# Introduction

*The CRC Concise Encyclopedia of Mathematics* is a compendium of mathematical definitions, formulas, figures, tabulations, and references. It is written in an informal style intended to make it accessible to a broad spectrum of readers with a wide range of mathematical backgrounds and interests. Although mathematics is a fascinating subject, it all too frequently is clothed in specialized jargon and dry formal exposition that make many interesting and useful mathematical results inaccessible to laypeople. This problem is often further compounded by the difficulty in locating concrete and easily understood examples. To give perspective to a subject, I find it helpful to learn why it is useful, how it is connected to other areas of mathematics and science, and how it is actually implemented. While a picture may be worth a thousand words, explicit examples are worth at least a few hundred! This work attempts to provide enough details to give the reader a flavor for a subject without getting lost in minutiae. While absolute rigor may suffer somewhat, I hope the improvement in usefulness and readability will more than make up for the deficiencies of this approach.

The format of this work is somewhere between a handbook, a dictionary, and an encyclopedia. It differs from existing dictionaries of mathematics in a number of important ways. First, the entire text and all the equations and figures are available in searchable electronic form on CD-ROM. Second, the entries are extensively cross-linked and cross-referenced, not only to related entries but also to many external sites on the Internet. This makes locating information very convenient. It also provides a highly efficient way to “navigate” from one related concept to another, a feature that is especially powerful in the electronic version. Standard mathematical references, combined with a few popular ones, are also given at the end of most entries to facilitate additional reading and exploration. In the interests of offering abundant examples, this work also contains a large number of explicit formulas and derivations, providing a ready place to locate a particular formula, as well as including the framework for understanding where it comes from.

The selection of topics in this work is more extensive than in most mathematical dictionaries (e.g., Borowski and Borwein’s *HarperCollins Dictionary of Mathematics* and Jeans and Jeans’ *Mathematics Dictionary*). At the same time, the descriptions are more accessible than in “technical” mathematical encyclopedias (e.g., Hazewinkel’s *Encyclopaedia of Mathematics* and Iyanaga’s *Encyclopedic Dictionary of Mathematics*). While the latter remain models of accuracy and rigor, they are not terribly useful to the undergraduate, research scientist, or recreational mathematician. In this work, the most useful, interesting, and entertaining (at least to my mind) aspects of topics are discussed in addition to their technical definitions. For example, in my entry for pi ( $\pi$ ), the definition in terms of the diameter and circumference of a circle is supplemented by a great many formulas and series for pi, including some of the amazing discoveries of Ramanujan. These formulas are comprehensible to readers with only minimal mathematical background, and are interesting to both those with and without formal mathematics training. However, they have not previously been collected in a single convenient location. For this reason, I hope that, in addition to serving as a reference source, this work has some of the same flavor and appeal of Martin Gardner’s delightful *Scientific American* columns.

Everything in this work has been compiled by me alone. I am an astronomer by training, but have picked up a fair bit of mathematics along the way. It never ceases to amaze me how mathematical connections weave their way through the physical sciences. It frequently transpires that some piece of recently acquired knowledge turns out to be just what I need to solve some apparently unrelated problem. I have therefore developed the habit of picking up and storing away odd bits of information for future use. This work has provided a mechanism for organizing what has turned out to be a fairly large collection of mathematics. I have also found it very difficult to find clear yet accessible explanations of technical mathematics unless I already have some familiarity with the subject. I hope this encyclopedia will provide jumping-off points for people who are interested in the subjects listed here but who, like me, are not necessarily experts.

The encyclopedia has been compiled over the last 11 years or so, beginning in my college years and continuing during graduate school. The initial document was written in *Microsoft Word*® on a Mac Plus® computer, and had reached about 200 pages by the time I started graduate school in 1990. When Andrew Treverrow made his *OrTeX* program available for the Mac, I began the task of converting all my documents to *TeX*, resulting in a vast improvement in readability. While undertaking the *Word* to *TeX* conversion, I also began cross-referencing entries, anticipating that eventually I would be able to convert the entire document

to hypertext. This hope was realized beginning in 1995, when the Internet explosion was in full swing and I learned of Nikos Drakos's excellent  $\text{T}_\text{E}\text{X}$  to HTML converter,  $\text{L}^{\text{A}}\text{T}_\text{E}\text{X}2\text{HTML}$ . After some additional effort, I was able to post an HTML version of my encyclopedia to the World Wide Web, currently located at [www.astro.virginia.edu/~eww6n/math/](http://www.astro.virginia.edu/~eww6n/math/).

The selection of topics included in this compendium is not based on any fixed set of criteria, but rather reflects my own random walk through mathematics. In truth, there is no good way of selecting topics in such a work. The mathematician James Sylvester may have summed up the situation most aptly. According to Sylvester (as quoted in the introduction to Ian Stewart's book *From Here to Infinity*), "Mathematics is not a book confined within a cover and bound between brazen clasps, whose contents it needs only patience to ransack; it is not a mine, whose treasures may take long to reduce into possession, but which fill only a limited number of veins and lodes; it is not a soil, whose fertility can be exhausted by the yield of successive harvests; it is not a continent or an ocean, whose area can be mapped out and its contour defined; it is as limitless as that space which it finds too narrow for its aspiration; its possibilities are as infinite as the worlds which are forever crowding in and multiplying upon the astronomer's gaze; it is as incapable of being restricted within assigned boundaries or being reduced to definitions of permanent validity, as the consciousness of life."

Several of Sylvester's points apply particularly to this undertaking. As he points out, mathematics itself cannot be confined to the pages of a book. The results of mathematics, however, are shared and passed on primarily through the printed (and now electronic) medium. While there is no danger of mathematical results being lost through lack of dissemination, many people miss out on fascinating and useful mathematical results simply because they are not aware of them. Not only does collecting many results in one place provide a single starting point for mathematical exploration, but it should also lessen the aggravation of encountering explanations for new concepts which themselves use unfamiliar terminology. In this work, the reader is only a cross-reference (or a mouse click) away from the necessary background material. As to Sylvester's second point, the very fact that the quantity of mathematics is so great means that any attempt to catalog it with any degree of completeness is doomed to failure. This certainly does not mean that it's not worth trying. Strangely, except for relatively small works usually on particular subjects, there do not appear to have been any substantial attempts to collect and display in a place of prominence the treasure trove of mathematical results that have been discovered (invented?) over the years (one notable exception being Sloane and Plouffe's *Encyclopedia of Integer Sequences*). This work, the product of the "gazing" of a single astronomer, attempts to fill that omission.

Finally, a few words about logistics. Because of the alphabetical listing of entries in the encyclopedia, neither table of contents nor index are included. In many cases, a particular entry of interest can be located from a cross-reference (indicated in SMALL CAPS TYPEFACE in the text) in a related article. In addition, most articles are followed by a "see also" list of related entries for quick navigation. This can be particularly useful if you are looking for a specific entry (say, "Zeno's Paradoxes"), but have forgotten the exact name. By examining the "see also" list at bottom of the entry for "Paradox," you will likely recognize Zeno's name and thus quickly locate the desired entry.

The alphabetization of entries contains a few peculiarities which need mentioning. All entries beginning with a numeral are ordered by increasing value and appear before the first entry for "A." In multiple-word entries containing a space or dash, the space or dash is treated as a character which precedes "a," so entries appear in the following order: "Sum," "Sum P. . .," "Sum-P. . .," and "Summary." One exception is that in a series of entries where a trailing "s" appears in some and not others, the trailing "s" is ignored in the alphabetization. Therefore, entries involving Euclid would be alphabetized as follows: "Euclid's Axioms," "Euclid Number," "Euclidean Algorithm." Because of the non-standard nomenclature that ensues from naming mathematical results after their discoverers, an important result such as the "Pythagorean Theorem" is written variously as "Pythagoras's Theorem," the "Pythagoras Theorem," etc. In this encyclopedia, I have endeavored to use the most widely accepted form. I have also tried to consistently give entry titles in the singular (e.g., "Knot" instead of "Knots").

In cases where the same word is applied in different contexts, the context is indicated in parentheses or appended to the end. Examples of the first type are "Crossing Number (Graph)" and "Crossing Number (Link)." Examples of the second type are "Convergent Sequence" and "Convergent Series." In the case of an entry like "Euler Theorem," which may describe one of three or four different formulas, I have taken the liberty of adding descriptive words ("Euler's *Something* Theorem") to all variations, or kept the standard

name for the most commonly used variant and added descriptive words for the others. In cases where specific examples are derived from a general concept, em dashes (—) are used (for example, “Fourier Series,” “Fourier Series—Power Series,” “Fourier Series—Square Wave,” “Fourier Series—Triangle”). The decision to put a possessive ’s at the end of a name or to use a lone trailing apostrophe is based on whether the final “s” is pronounced. “Gauss’s Theorem” is therefore written out, whereas “Archimedes’ Recurrence Formula” is not. Finally, given the absence of a definitive stylistic convention, plurals of numerals are written without an apostrophe (e.g., 1990s instead of 1990’s).

In an endeavor of this magnitude, errors and typographical mistakes are inevitable. The blame for these lies with me alone. Although the current length makes extensive additions in a printed version problematic, I plan to continue updating, correcting, and improving the work.

Eric Weisstein

Charlottesville, Virginia  
August 8, 1998

## Acknowledgments

Although I alone have compiled and typeset this work, many people have contributed indirectly and directly to its creation. I have not yet had the good fortune to meet Donald Knuth of Stanford University, but he is unquestionably the person most directly responsible for making this work possible. Before his mathematical typesetting program  $\mathrm{T}_{\mathrm{E}}\mathrm{X}$ , it would have been impossible for a single individual to compile such a work as this. Had Prof. Bateman owned a personal computer equipped with  $\mathrm{T}_{\mathrm{E}}\mathrm{X}$ , perhaps his shoe box of notes would not have had to await the labors of Erdelyi, Magnus, and Oberhettinger to become a three-volume work on mathematical functions. Andrew Trevorrow's shareware implementation of  $\mathrm{T}_{\mathrm{E}}\mathrm{X}$  for the Macintosh,  $\mathrm{OzT}_{\mathrm{E}}\mathrm{X}$  ([www.kagi.com/authors/akt/oztex.html](http://www.kagi.com/authors/akt/oztex.html)), was also of fundamental importance. Nikos Drakos and Ross Moore have provided another building block for this work by developing the  $\mathrm{L}^{\mathrm{A}}\mathrm{T}_{\mathrm{E}}\mathrm{X}2\mathrm{HTML}$  program ([www-dsdl.llnl.gov/files/programs/unix/latex2html/manual/manual.html](http://www-dsdl.llnl.gov/files/programs/unix/latex2html/manual/manual.html)), which has allowed me to easily maintain and update an on-line version of the encyclopedia long before it existed in book form.

I would like to thank Steven Finch of MathSoft, Inc., for his interesting on-line essays about mathematical constants ([www.mathsoft.com/asolve/constant/constant.html](http://www.mathsoft.com/asolve/constant/constant.html)), and also for his kind permission to reproduce excerpts from some of these essays. I hope that Steven will someday publish his detailed essays in book form. Thanks also to Neil Sloane and Simon Plouffe for compiling and making available the printed and on-line ([www.research.att.com/~njas/sequences/](http://www.research.att.com/~njas/sequences/)) versions of the *Encyclopedia of Integer Sequences*, an immensely valuable compilation of useful information which represents a truly mind-boggling investment of labor.

Thanks to Robert Dickau, Simon Plouffe, and Richard Schroepel for reading portions of the manuscript and providing a number of helpful suggestions and additions. Thanks also to algebraic topologist Ryan Budney for sharing some of his expertise, to Charles Walkden for his helpful comments about dynamical systems theory, and to Lambros Lambrou for his contributions. Thanks to David W. Wilson for a number of helpful comments and corrections. Thanks to Dale Rolfsen, compiler James Bailey, and artist Ali Roth for permission to reproduce their beautiful knot and link diagrams. Thanks to Gavin Theobald for providing diagrams of his masterful polygonal dissections. Thanks to Wolfram Research, not only for creating an indispensable mathematical tool in *Mathematica*®, but also for permission to include figures from the *Mathematica*® book and *MathSource* repository for the braid, conical spiral, double helix, Enneper's surfaces, Hadamard matrix, helicoid, helix, Henneberg's minimal surface, hyperbolic polyhedra, Klein bottle, Maeder's "owl" minimal surface, Penrose tiles, polyhedron, and Scherk's minimal surfaces entries.

Sincere thanks to Judy Schroeder for her skill and diligence in the monumental task of proofreading the entire document for syntax. Thanks also to Bob Stern, my executive editor from *CRC Press*, for his encouragement, and to Mimi Williams of *CRC Press* for her careful reading of the manuscript for typographical and formatting errors. As this encyclopedia's entry on *PROOFREADING MISTAKES* shows, the number of mistakes that are expected to remain after three independent proofreadings is much lower than the original number, but unfortunately still nonzero. Many thanks to the library staff at the University of Virginia, who have provided invaluable assistance in tracking down many an obscure citation. Finally, I would like to thank the hundreds of people who took the time to e-mail me comments and suggestions while this work was in its formative stages. Your continued comments and feedback are very welcome.

# Numerals

## 0

see ZERO

## 1

The number one (1) is the first POSITIVE INTEGER. It is an ODD NUMBER. Although the number 1 used to be considered a PRIME NUMBER, it requires special treatment in so many definitions and applications involving primes greater than or equal to 2 that it is usually placed into a class of its own. The number 1 is sometimes also called "unity," so the  $n$ th roots of 1 are often called the  $n$ th ROOTS OF UNITY. FRACTIONS having 1 as a NUMERATOR are called UNIT FRACTIONS. If only one root, solution, etc., exists to a given problem, the solution is called UNIQUE.

The GENERATING FUNCTION have all COEFFICIENTS 1 is given by

$$\frac{1}{1-x} = 1 + x + x^2 + x^3 + x^4 + \dots$$

see also 2, 3, EXACTLY ONE, ROOT OF UNITY, UNIQUE, UNIT FRACTION, ZERO

## 2

The number two (2) is the second POSITIVE INTEGER and the first PRIME NUMBER. It is EVEN, and is the only EVEN PRIME (the PRIMES other than 2 are called the ODD PRIMES). The number 2 is also equal to its FACTORIAL since  $2! = 2$ . A quantity taken to the POWER 2 is said to be SQUARED. The number of times  $k$  a given BINARY number  $b_n \dots b_2 b_1 b_0$  is divisible by 2 is given by the position of the first  $b_k = 1$ , counting from the right. For example,  $12 = 1100$  is divisible by 2 twice, and  $13 = 1101$  is divisible by 2 0 times.

see also 1, BINARY, 3, SQUARED, ZERO

## $2x \bmod 1$ Map

Let  $x_0$  be a REAL NUMBER in the CLOSED INTERVAL  $[0, 1]$ , and generate a SEQUENCE using the MAP

$$x_{n+1} \equiv 2x_n \pmod{1}. \quad (1)$$

Then the number of periodic ORBITS of period  $p$  (for  $p$  PRIME) is given by

$$N_p = \frac{2^p - 2}{p}. \quad (2)$$

Since a typical ORBIT visits each point with equal probability, the NATURAL INVARIANT is given by

$$\rho(x) = 1. \quad (3)$$

see also TENT MAP

## References

## 3

3 is the only INTEGER which is the sum of the preceding POSITIVE INTEGERS ( $1 + 2 = 3$ ) and the only number which is the sum of the FACTORIALS of the preceding POSITIVE INTEGERS ( $1! + 2! = 3$ ). It is also the first ODD PRIME. A quantity taken to the POWER 3 is said to be CUBED.

see also 1, 2,  $3x + 1$  MAPPING, CUBED, PERIOD THREE THEOREM, SUPER-3 NUMBER, TERNARY, THREE-COLORABLE, ZERO

## $3x + 1$ Mapping

see COLLATZ PROBLEM

## 10

The number 10 (ten) is the basis for the DECIMAL system of notation. In this system, each "decimal place" consists of a DIGIT 0-9 arranged such that each DIGIT is multiplied by a POWER of 10, decreasing from left to right, and with a decimal place indicating the  $10^0 = 1$ s place. For example, the number 1234.56 specifies

$$1 \times 10^3 + 2 \times 10^2 + 3 \times 10^1 + 4 \times 10^0 + 5 \times 10^{-1} + 6 \times 10^{-2}.$$

The decimal places to the left of the decimal point are 1, 10, 100, 1000, 10000, 100000, 1000000, 10000000, ... (Sloane's A011557), called one, ten, HUNDRED, THOUSAND, ten thousand, hundred thousand, MILLION, 10 million, 100 million, and so on. The names of subsequent decimal places for LARGE NUMBERS differ depending on country.

Any POWER of 10 which can be written as the PRODUCT of two numbers not containing 0s must be of the form  $2^n \cdot 5^n = 10^n$  for  $n$  an INTEGER such that neither  $2^n$  nor  $5^n$  contains any ZEROS. The largest known such number is

$$10^{33} = 2^{33} \cdot 5^{33} \\ = 8,589,934,592 \cdot 116,415,321,826,934,814,453,125.$$

A complete list of known such numbers is

$$\begin{aligned} 10^1 &= 2^1 \cdot 5^1 \\ 10^2 &= 2^2 \cdot 5^2 \\ 10^3 &= 2^3 \cdot 5^3 \\ 10^4 &= 2^4 \cdot 5^4 \\ 10^5 &= 2^5 \cdot 5^5 \\ 10^6 &= 2^6 \cdot 5^6 \\ 10^7 &= 2^7 \cdot 5^7 \\ 10^9 &= 2^9 \cdot 5^9 \\ 10^{18} &= 2^{18} \cdot 5^{18} \\ 10^{33} &= 2^{33} \cdot 5^{33} \end{aligned}$$

(Madachy 1979). Since all POWERS of 2 with exponents  $n \leq 4.6 \times 10^7$  contain at least one ZERO (M. Cook), no

other POWER of ten less than 46 million can be written as the PRODUCT of two numbers not containing 0s.

see also BILLION, DECIMAL, HUNDRED, LARGE NUMBER, MILLIARD, MILLION, THOUSAND, TRILLION, ZERO

## 12

One DOZEN, or a twelfth of a GROSS.

see also DOZEN, GROSS

## 13

A NUMBER traditionally associated with bad luck. A so-called BAKER'S DOZEN is equal to 13. Fear of the number 13 is called TRISKAIDEKAPHOBIA.

see also BAKER'S DOZEN, FRIDAY THE THIRTEENTH, TRISKAIDEKAPHOBIA

## 15

see 15 PUZZLE, FIFTEEN THEOREM

## 15 Puzzle

1	2	3	4
5	6	7	8
9	10	11	12
13	14	15	

A puzzle introduced by Sam Loyd in 1878. It consists of 15 squares numbered from 1 to 15 which are placed in a  $4 \times 4$  box leaving one position out of the 16 empty. The goal is to rearrange the squares from a given arbitrary starting arrangement by sliding them one at a time into the configuration shown above. For some initial arrangements, this rearrangement is possible, but for others, it is not.

To address the solubility of a given initial arrangement, proceed as follows. If the SQUARE containing the number  $i$  appears "before" (reading the squares in the box from left to right and top to bottom)  $n$  numbers which are less than  $i$ , then call it an inversion of order  $n$ , and denote it  $n_i$ . Then define

$$N \equiv \sum_{i=1}^{15} n_i = \sum_{i=2}^{15} n_i,$$

where the sum need run only from 2 to 15 rather than 1 to 15 since there are no numbers less than 1 (so  $n_1$  must equal 0). If  $N$  is EVEN, the position is possible, otherwise it is not. This can be formally proved using ALTERNATING GROUPS. For example, in the following arrangement

2	1	3	4
5	6	7	8
9	10	11	12
13	14	15	

$n_2 = 1$  (2 precedes 1) and all other  $n_i = 0$ , so  $N = 1$  and the puzzle cannot be solved.

## 18-Point Problem

Place a point somewhere on a LINE SEGMENT. Now place a second point and number it 2 so that each of the points is in a different half of the LINE SEGMENT. Continue, placing every  $N$ th point so that all  $N$  points are on different  $(1/N)$ th of the LINE SEGMENT. Formally, for a given  $N$ , does there exist a sequence of real numbers  $x_1, x_2, \dots, x_N$  such that for every  $n \in \{1, \dots, N\}$  and every  $k \in \{1, \dots, n\}$ , the inequality

$$\frac{k-1}{n} \leq x_k < \frac{k}{n}$$

holds for some  $i \in \{1, \dots, n\}$ ? Surprisingly, it is only possible to place 17 points in this manner (Berlekamp and Graham 1970, Warmus 1976).

Steinhaus (1979) gives a 14-point solution (0.06, 0.55, 0.77, 0.39, 0.96, 0.28, 0.64, 0.13, 0.88, 0.48, 0.19, 0.71, 0.35, 0.82), and Warmus (1976) gives the 17-point solution

$$\begin{aligned} \frac{4}{7} \leq x_1 < \frac{7}{12}, \frac{2}{7} \leq x_2 < \frac{5}{17}, \frac{16}{17} \leq x_3 < 1, \frac{1}{14} \leq x_4 < \frac{1}{13}, \\ \frac{8}{11} \leq x_5 < \frac{11}{15}, \frac{5}{11} \leq x_6 < \frac{6}{13}, \frac{1}{7} \leq x_7 < \frac{2}{13}, \frac{14}{17} \leq x_8 < \frac{5}{6}, \\ \frac{3}{8} \leq x_9 < \frac{5}{13}, \frac{11}{17} \leq x_{10} < \frac{2}{3}, \frac{3}{14} \leq x_{11} < \frac{3}{13}, \\ \frac{15}{17} \leq x_{12} < \frac{11}{12}, \frac{1}{2} \leq x_{12} < \frac{9}{17}, 0 \leq x_{14} < \frac{1}{17}, \\ \frac{13}{17} \leq x_{15} < \frac{4}{5}, \frac{5}{16} \leq x_{16} < \frac{6}{17}, \frac{10}{17} \leq x_{17} < \frac{11}{17}. \end{aligned}$$

Warmus (1976) states that there are 768 patterns of 17-point solutions (counting reversals as equivalent).

#### 24-Cell

A finite regular 4-D POLYTOPE with SCHLÄFLI SYMBOL  $\{3, 4, 3\}$ . Coxeter (1969) gives a list of the VERTEX positions. The EVEN coefficients of the  $D_4$  lattice are 1, 24, 24, 96, ... (Sloane's A004011), and the 24 shortest vectors in this lattice form the 24-cell (Coxeter 1973, Conway and Sloane 1993, Sloane and Plouffe 1995).

#### 144

A DOZEN DOZEN, also called a GROSS. 144 is a SQUARE NUMBER and a SUM-PRODUCT NUMBER.

see also DOZEN

#### 196-Algorithm

Take any POSITIVE INTEGER of two DIGITS or more, reverse the DIGITS, and add to the original number. Now repeat the procedure with the SUM so obtained. This procedure quickly produces PALINDROMIC NUMBERS for most INTEGERS. For example, starting with the number 5280 produces (5280, 6105, 11121, 23232). The end results of applying the algorithm to 1, 2, 3, ... are 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 11, 33, 44, 55, 66, 77, 88, 99, 121, ... (Sloane's A033865). The value for 89 is especially large, being 8813200023188.

The first few numbers not known to produce PALINDROMES are 196, 887, 1675, 7436, 13783, ... (Sloane's A006960), which are simply the numbers obtained by iteratively applying the algorithm to the number 196. This number therefore lends itself to the name of the ALGORITHM.

The number of terms  $a(n)$  in the iteration sequence required to produce a PALINDROMIC NUMBER from  $n$  (i.e.,  $a(n) = 1$  for a PALINDROMIC NUMBER,  $a(n) = 2$  if a PALINDROMIC NUMBER is produced after a single iteration of the 196-algorithm, etc.) for  $n = 1, 2, \dots$  are 1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1, 2, 2, 2, 2, 2, 2, 2, 3, 2, 2, 1, ... (Sloane's A030547). The smallest numbers which require  $n = 0, 1, 2, \dots$  iterations to reach a palindrome are 0, 10, 19, 59, 69, 166, 79, 188, ... (Sloane's A023109).

**239**

Some interesting properties (as well as a few arcane ones not reiterated here) of the number 239 are discussed in Beeler *et al.* (1972, Item 63). 239 appears in MACHIN'S FORMULA

$$\frac{1}{4}\pi = 4 \tan\left(\frac{1}{5}\right) - \tan^{-1}\left(\frac{1}{239}\right),$$

which is related to the fact that

$$2 \cdot 13^4 - 1 = 239^2,$$

which is why 239/169 is the 7th CONVERGENT of  $\sqrt{2}$ . Another pair of INVERSE TANGENT FORMULAS involving 239 is

$$\begin{aligned} \tan^{-1}\left(\frac{1}{239}\right) &= \tan^{-1}\left(\frac{1}{70}\right) - \tan^{-1}\left(\frac{1}{99}\right) \\ &= \tan^{-1}\left(\frac{1}{408}\right) + \tan^{-1}\left(\frac{1}{577}\right). \end{aligned}$$

239 needs 4 SQUARES (the maximum) to express it, 9 CUBES (the maximum, shared only with 23) to express it, and 19 fourth POWERS (the maximum) to express it (see WARING'S PROBLEM). However, 239 doesn't need the maximum number of fifth POWERS (Beeler *et al.* 1972, Item 63).

**257-gon**

257 is a FERMAT PRIME, and the 257-gon is therefore a CONSTRUCTIBLE POLYGON using COMPASS and STRAIGHTEDGE, as proved by Gauss. An illustration of the 257-gon is not included here, since its 257 segments so closely resemble a CIRCLE. Richelot and Schwenkenwein found constructions for the 257-gon in 1832 (Coxeter 1969). De Temple (1991) gives a construction using 150 CIRCLES (24 of which are CARLYLE CIRCLES) which has GEOMETROGRAPHY symbol  $94S_1 + 47S_2 + 275C_1 + 0C_2 + 150C_3$  and SIMPLICITY 566.

**2187**

The digits in the number 2187 form the two VAMPIRE NUMBERS:  $21 \times 87 = 1827$  and  $2187 = 27 \times 81$ .

References

Gardner, M. "Lucky Numbers and 2187." *Math. Intell.* **19**, 26-29, Spring 1997.

**65537-gon**

65537 is the largest known FERMAT PRIME, and the 65537-gon is therefore a CONSTRUCTIBLE POLYGON using COMPASS and STRAIGHTEDGE, as proved by Gauss. The 65537-gon has so many sides that it is, for all intents and purposes, indistinguishable from a CIRCLE using any reasonable printing or display methods. Hermes spent 10 years on the construction of the 65537-gon at Göttingen around 1900 (Coxeter 1969). De Temple (1991) notes that a GEOMETRIC CONSTRUCTION can be done using 1332 or fewer CARLYLE CIRCLES.

# A

## A-Integrable

A generalization of the LEBESGUE INTEGRAL. A MEASURABLE FUNCTION  $f(x)$  is called A-integrable over the CLOSED INTERVAL  $[a, b]$  if

$$m\{x : |f(x)| > n\} = \mathcal{O}(n^{-1}), \quad (1)$$

where  $m$  is the LEBESGUE MEASURE, and

$$I = \lim_{n \rightarrow \infty} \int_a^b [f(x)]_n dx \quad (2)$$

exists, where

$$[f(x)]_n = \begin{cases} f(x) & \text{if } |f(x)| \leq n \\ 0 & \text{if } |f(x)| > n. \end{cases} \quad (3)$$

## References

## A-Sequence

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

An INFINITE SEQUENCE of POSITIVE INTEGERS  $a_i$  satisfying

$$1 \leq a_1 < a_2 < a_3 < \dots \quad (1)$$

is an A-sequence if no  $a_k$  is the SUM of two or more distinct earlier terms (Guy 1994). Erdős (1962) proved

$$S(A) \equiv \sup_{\text{all } A \text{ sequences}} \sum_{k=1}^{\infty} \frac{1}{a_k} < 103. \quad (2)$$

Any A-sequence satisfies the CHI INEQUALITY (Levine and O'Sullivan 1977), which gives  $S(A) < 3.9998$ . Abbott (1987) and Zhang (1992) have given a bound from below, so the best result to date is

$$2.0649 < S(A) < 3.9998. \quad (3)$$

Levine and O'Sullivan (1977) conjectured that the sum of RECIPROALS of an A-sequence satisfies

$$S(A) \leq \sum_{k=1}^{\infty} \frac{1}{\chi_k} = 3.01\dots, \quad (4)$$

where  $\chi_i$  are given by the LEVINE-O'SULLIVAN GREEDY ALGORITHM.

## AAA Theorem

Specifying three ANGLES  $A$ ,  $B$ , and  $C$  does not uniquely define a TRIANGLE, but any two TRIANGLES with the same ANGLES are SIMILAR. Specifying two ANGLES of a TRIANGLE automatically gives the third since the sum of ANGLES in a TRIANGLE sums to  $180^\circ$  ( $\pi$  RADIANS), i.e.,

$$C = \pi - A - B.$$

see also AAS THEOREM, ASA THEOREM, ASS THEOREM, SAS THEOREM, SSS THEOREM, TRIANGLE

## AAS Theorem

Specifying two angles  $A$  and  $B$  and a side  $a$  uniquely determines a TRIANGLE with AREA

$$K = \frac{a^2 \sin B \sin C}{2 \sin A} = \frac{a^2 \sin B \sin(\pi - A - B)}{2 \sin A}. \quad (1)$$

The third angle is given by

$$C = \pi - A - B, \quad (2)$$

since the sum of angles of a TRIANGLE is  $180^\circ$  ( $\pi$  RADIANS). Solving the LAW OF SINES

$$\frac{a}{\sin A} = \frac{b}{\sin B} \quad (3)$$

for  $b$  gives

$$b = a \frac{\sin B}{\sin A}. \quad (4)$$

Finally,

$$c = b \cos A + a \cos B = a(\sin B \cot A + \cos B) \quad (5)$$

$$= a \sin B(\cot A + \cot B). \quad (6)$$

see also AAA THEOREM, ASA THEOREM, ASS THEOREM, SAS THEOREM, SSS THEOREM, TRIANGLE

## Abacus

A mechanical counting device consisting of a frame holding a series of parallel rods on each of which beads are strung. Each bead represents a counting unit, and each rod a place value. The primary purpose of the abacus is not to perform actual computations, but to provide a quick means of storing numbers during a calculation. Abaci were used by the Japanese and Chinese, as well as the Romans.

see also ROMAN NUMERAL, SLIDE RULE

## abc Conjecture

A CONJECTURE due to J. Oesterlé and D. W. Masser. It states that, for any INFINITESIMAL  $\epsilon > 0$ , there exists a CONSTANT  $C_\epsilon$  such that for any three RELATIVELY PRIME INTEGERS  $a, b, c$  satisfying

$$a + b = c,$$

the INEQUALITY

$$\max\{|a|, |b|, |c|\} \leq C_\epsilon \prod_{p|abc} p^{1+\epsilon}$$

holds, where  $p|abc$  indicates that the PRODUCT is over PRIMES  $p$  which DIVIDE the PRODUCT  $abc$ . If this CONJECTURE were true, it would imply FERMAT'S LAST THEOREM for sufficiently large POWERS (Goldfeld 1996). This is related to the fact that the abc conjecture implies that there are at least  $C \ln x$  WIEFERICH PRIMES  $\leq x$  for some constant  $C$  (Silverman 1988, Vardi 1991). see also FERMAT'S LAST THEOREM, MASON'S THEOREM, WIEFERICH PRIME

## Abel's Functional Equation

Let  $\text{Li}_2(x)$  denote the DILOGARITHM, defined by

$$\text{Li}_2(x) = \sum_{n=1}^{\infty} \frac{x^n}{n^2},$$

then

$$\begin{aligned} \text{Li}_2(x) + \text{Li}_2(y) + \text{Li}_2(xy) + \text{Li}_2\left(\frac{x(1-y)}{1-xy}\right) \\ + \text{Li}_2\left(\frac{y(1-x)}{1-xy}\right) = 3\text{Li}_2(1). \end{aligned}$$

see also DILOGARITHM, POLYLOGARITHM, RIEMANN ZETA FUNCTION

## Abelian Group

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

A GROUP for which the elements COMMUTE (i.e.,  $AB = BA$  for all elements  $A$  and  $B$ ) is called an Abelian group. All CYCLIC GROUPS are Abelian, but an Abelian group is not necessarily CYCLIC. All SUBGROUPS of an Abelian group are NORMAL. In an Abelian group, each element is in a CONJUGACY CLASS by itself, and the CHARACTER TABLE involves POWERS of a single element known as a GENERATOR.

No general formula is known for giving the number of nonisomorphic FINITE GROUPS of a given ORDER. However, the number of nonisomorphic Abelian FINITE GROUPS  $a(n)$  of any given ORDER  $n$  is given by writing  $n$  as

$$n = \prod_i p_i^{\alpha_i}, \quad (1)$$

where the  $p_i$  are distinct PRIME FACTORS, then

$$a(n) = \prod_i P(\alpha_i), \quad (2)$$

where  $P$  is the PARTITION FUNCTION. This gives 1, 1, 1, 2, 1, 1, 1, 3, 2, ... (Sloane's A000688). The smallest orders for which  $n = 1, 2, 3, \dots$  nonisomorphic Abelian groups exist are 1, 4, 8, 36, 16, 72, 32, 900, 216, 144, 64, 1800, 0, 288, 128, ... (Sloane's A046056), where 0 denotes an impossible number (i.e., not a product of partition numbers) of nonisomorphic Abelian, groups. The "missing" values are 13, 17, 19, 23, 26, 29, 31, 34, 37, 38, 39, 41, 43, 46, ... (Sloane's A046064). The incrementally largest numbers of Abelian groups as a function of order are 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56, 77, 101, ... (Sloane's A046054), which occur for orders 1, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, ... (Sloane's A046055).

The KRONECKER DECOMPOSITION THEOREM states that every FINITE Abelian group can be written as a DIRECT PRODUCT of CYCLIC GROUPS of PRIME POWER ORDERS. If the ORDERS of a FINITE GROUP is a PRIME  $p$ , then there exists a single Abelian group of order  $p$  (denoted  $Z_p$ ) and no non-Abelian groups. If the ORDERS is a prime squared  $p^2$ , then there are two Abelian groups (denoted  $Z_{p^2}$  and  $Z_p \otimes Z_p$ . If the ORDERS is

a prime cubed  $p^3$ , then there are three Abelian groups (denoted  $Z_p \otimes Z_p \otimes Z_p$ ,  $Z_p \otimes Z_{p^2}$ , and  $Z_{p^3}$ ), and five groups total. If the order is a PRODUCT of two primes  $p$  and  $q$ , then there exists exactly one Abelian group of order  $pq$  (denoted  $Z_p \otimes Z_q$ ).

Another interesting result is that if  $a(n)$  denotes the number of nonisomorphic Abelian groups of ORDER  $n$ , then

$$\sum_{n=1}^{\infty} a(n)n^{-s} = \zeta(s)\zeta(2s)\zeta(3s)\cdots, \quad (3)$$

where  $\zeta(s)$  is the RIEMANN ZETA FUNCTION. Srinivasan (1973) has also shown that

$$\sum_{n=1}^N a(n) = A_1 N + A_2 N^{1/2} + A_3 N^{1/3} + \mathcal{O}[x^{105/407}(\ln x)^2], \quad (4)$$

where

$$A_k \equiv \prod_{\substack{j=1 \\ j \neq k}} \zeta\left(\frac{j}{k}\right) = \begin{cases} 2.294856591\dots & \text{for } k=1 \\ -14.6475663\dots & \text{for } k=2 \\ 118.6924619\dots & \text{for } k=3, \end{cases} \quad (5)$$

and  $\zeta$  is again the RIEMANN ZETA FUNCTION. [Richert (1952) incorrectly gave  $A_3 = 114$ .] DeKoninck and Ivic (1980) showed that

$$\sum_{n=1}^N \frac{1}{a(n)} = BN + \mathcal{O}[\sqrt{N}(\ln N)^{-1/2}], \quad (6)$$

where

$$B \equiv \prod \left\{ 1 - \sum_{k=2}^{\infty} \left[ \frac{1}{P(k-2)} - \frac{1}{P(k)} \right] \frac{1}{p^k} \right\} = 0.752\dots \quad (7)$$

is a product over PRIMES. Bounds for the number of nonisomorphic non-Abelian groups are given by Neumann (1969) and Pyber (1993).

### Abel's Identity

Given a homogeneous linear SECOND-ORDER ORDINARY DIFFERENTIAL EQUATION,

$$y'' + P(x)y' + Q(x)y = 0, \quad (1)$$

call the two linearly independent solutions  $y_1(x)$  and  $y_2(x)$ . Then

$$y_1''(x) + P(x)y_1'(x) + Q(x)y_1 = 0 \quad (2)$$

$$y_2''(x) + P(x)y_2'(x) + Q(x)y_2 = 0. \quad (3)$$

Now, take  $y_1 \times (3) - y_2 \times (2)$ ,

$$y_1[y_2'' + P(x)y_2' + Q(x)y_2] - y_2[y_1'' + P(x)y_1' + Q(x)y_1] = 0 \quad (4)$$

$$(y_1y_2'' - y_2y_1'') + P(y_1y_2' - y_2y_1') + Q(y_1y_2 - y_2y_1) = 0 \quad (5)$$

$$(y_1y_2'' - y_2y_1'') + P(y_1y_2' - y_2y_1') = 0. \quad (6)$$

Now, use the definition of the WRONSKIAN and take its DERIVATIVE,

$$W \equiv y_1y_2' - y_2y_1' \quad (7)$$

$$\begin{aligned} W' &= (y_1'y_2' + y_1y_2'') - (y_2'y_1' + y_2y_1'') \\ &= y_1y_2'' - y_2y_1''. \end{aligned} \quad (8)$$

Plugging  $W$  and  $W'$  into (6) gives

$$W' + PW = 0. \quad (9)$$

This can be rearranged to yield

$$\frac{dW}{W} = -P(x) dx \quad (10)$$

which can then be directly integrated to

$$\ln W = -C_1 \int P(x) dx, \quad (11)$$

where  $\ln x$  is the NATURAL LOGARITHM. A second integration then yields Abel's identity

$$W(x) = C_2 e^{-\int P(x) dx}, \quad (12)$$

where  $C_1$  is a constant of integration and  $C_2 \equiv e^{C_1}$ .

### Abel's Inequality

Let  $\{f_n\}$  and  $\{a_n\}$  be SEQUENCES with  $f_n \geq f_{n+1} > 0$  for  $n = 1, 2, \dots$ , then

$$\left| \sum_{n=1}^m a_n f_n \right| \leq A f_1,$$

where

$$A = \max\{|a_1|, |a_1 + a_2|, \dots, |a_1 + a_2 + \dots + a_m|\}.$$

### Abelian Integral

An INTEGRAL of the form

$$\int_0^x \frac{dt}{\sqrt{R(t)}},$$

where  $R(t)$  is a POLYNOMIAL of degree  $> 4$ . They are also called HYPERELLIPTIC INTEGRALS.

see also ABELIAN FUNCTION, ELLIPTIC INTEGRAL

### Abel's Irreducibility Theorem

If one ROOT of the equation  $f(x) = 0$ , which is irreducible over a FIELD  $K$ , is also a ROOT of the equation  $F(x) = 0$  in  $K$ , then all the ROOTS of the irreducible equation  $f(x) = 0$  are ROOTS of  $F(x) = 0$ . Equivalently,  $F(x)$  can be divided by  $f(x)$  without a REMAINDER,

$$F(x) = f(x)F_1(x),$$

where  $F_1(x)$  is also a POLYNOMIAL over  $K$ .

**Abel's Test**

see ABEL'S UNIFORM CONVERGENCE TEST

**Abel's Theorem**

Given a TAYLOR SERIES

$$F(z) = \sum_{n=0}^{\infty} C_n z^n = \sum_{n=0}^{\infty} C_n r^n e^{in\theta}, \quad (1)$$

where the COMPLEX NUMBER  $z$  has been written in the polar form  $z = re^{i\theta}$ , examine the REAL and IMAGINARY PARTS

$$u(r, \theta) = \sum_{n=0}^{\infty} C_n r^n \cos(n\theta) \quad (2)$$

$$v(r, \theta) = \sum_{n=0}^{\infty} C_n r^n \sin(n\theta). \quad (3)$$

Abel's theorem states that, if  $u(1, \theta)$  and  $v(1, \theta)$  are CONVERGENT, then

$$u(1, \theta) + iv(1, \theta) = \lim_{r \rightarrow 1} f(re^{i\theta}). \quad (4)$$

Stated in words, Abel's theorem guarantees that, if a REAL POWER SERIES CONVERGES for some POSITIVE value of the argument, the DOMAIN of UNIFORM CONVERGENCE extends at least up to and including this point. Furthermore, the continuity of the sum function extends at least up to and including this point.

**Abel Transform**

The following INTEGRAL TRANSFORM relationship, known as the Abel transform, exists between two functions  $f(x)$  and  $g(t)$  for  $0 < \alpha < 1$ ,

$$f(x) = \int_0^x \frac{g(t) dt}{(x-t)^\alpha} \quad (1)$$

$$g(t) = -\frac{\sin(\pi\alpha)}{\pi} \frac{d}{dt} \int_0^t \frac{f(x) dx}{(x-t)^{1-\alpha}} \quad (2)$$

$$= -\frac{\sin(\pi\alpha)}{\pi} \left[ \int_0^t \frac{df}{dx} \frac{dx}{(t-x)^{1-\alpha}} + \frac{f(0)}{t^{1-\alpha}} \right]. \quad (3)$$

The Abel transform is used in calculating the radial mass distribution of galaxies and inverting planetary radio occultation data to obtain atmospheric information.

**Abel's Uniform Convergence Test**

Let  $\{u_n(x)\}$  be a SEQUENCE of functions. If

1.  $u_n(x)$  can be written  $u_n(x) = a_n f_n(x)$ ,
2.  $\sum a_n$  is CONVERGENT,
3.  $f_n(x)$  is a MONOTONIC DECREASING SEQUENCE (i.e.,  $f_{n+1}(x) \leq f_n(x)$ ) for all  $n$ , and
4.  $f_n(x)$  is BOUNDED in some region (i.e.,  $0 \leq f_n(x) \leq M$  for all  $x \in [a, b]$ )

then, for all  $x \in [a, b]$ , the SERIES  $\sum u_n(x)$  CONVERGES UNIFORMLY.

Murty, V. K. *Introduction to Abelian Varieties*. Providence, RI: Amer. Math. Soc., 1993.

**Abhyankar's Conjecture**

For a FINITE GROUP  $G$ , let  $p(G)$  be the SUBGROUP generated by all the SYLOW  $p$ -SUBGROUPS of  $G$ . If  $X$  is a projective curve in characteristic  $p > 0$ , and if  $x_0, \dots, x_t$  are points of  $X$  (for  $t > 0$ ), then a NECESSARY and SUFFICIENT condition that  $G$  occur as the GALOIS GROUP of a finite covering  $Y$  of  $X$ , branched only at the points  $x_0, \dots, x_t$ , is that the QUOTIENT GROUP  $G/p(G)$  has  $2g + t$  generators.

Raynaud (1994) solved the Abhyankar problem in the crucial case of the affine line (i.e., the projective line with a point deleted), and Harbater (1994) proved the full Abhyankar conjecture by building upon this special solution.

**Absolute Convergence**

A SERIES  $\sum_n u_n$  is said to CONVERGE absolutely if the SERIES  $\sum_n |u_n|$  CONVERGES, where  $|u_n|$  denotes the ABSOLUTE VALUE. If a SERIES is absolutely convergent, then the sum is independent of the order in which terms are summed. Furthermore, if the SERIES is multiplied by another absolutely convergent series, the product series will also converge absolutely.

*see also* CONDITIONAL CONVERGENCE, CONVERGENT SERIES, RIEMANN SERIES THEOREM

References

**Absolute Pseudoprime**

*see* CARMICHAEL NUMBER

**Absolute Square**

Also known as the squared NORM. The absolute square of a COMPLEX NUMBER  $z$  is written  $|z|^2$  and is defined as

$$|z|^2 \equiv zz^*, \quad (1)$$

where  $z^*$  denotes the COMPLEX CONJUGATE of  $z$ . For a REAL NUMBER, (1) simplifies to

$$|z|^2 = z^2. \quad (2)$$

If the COMPLEX NUMBER is written  $z = x + iy$ , then the absolute square can be written

$$|x + iy|^2 = x^2 + y^2. \quad (3)$$

An important identity involving the absolute square is given by

$$\begin{aligned} |a \pm be^{-i\delta}|^2 &= (a \pm be^{-i\delta})(a \pm be^{i\delta}) \\ &= a^2 + b^2 \pm ab(e^{i\delta} + e^{-i\delta}) \\ &= a^2 + b^2 \pm 2ab \cos \delta. \end{aligned} \quad (4)$$

If  $a = 1$ , then (4) becomes

$$\begin{aligned} |1 \pm be^{-i\delta}|^2 &= 1 + b^2 \pm 2b \cos \delta \\ &= 1 + b^2 \pm 2b[1 - 2\sin^2(\tfrac{1}{2}\delta)] \\ &= 1 \pm 2b + b^2 \mp 4b \sin^2(\tfrac{1}{2}\delta) \\ &= (1 \pm b)^2 \mp 4b \sin^2(\tfrac{1}{2}\delta). \end{aligned} \quad (5)$$

If  $a = 1$ , and  $b = 1$ , then

$$|1 - e^{-i\delta}|^2 = (1 - 1)^2 + 4 \cdot 1 \sin^2(\tfrac{1}{2}\delta) = 4 \sin^2(\tfrac{1}{2}\delta). \quad (6)$$

Finally,

$$\begin{aligned} |e^{i\phi_1} + e^{i\phi_2}|^2 &= (e^{i\phi_1} + e^{i\phi_2})(e^{-i\phi_1} + e^{-i\phi_2}) \\ &= 2 + e^{i(\phi_2 - \phi_1)} + e^{-i(\phi_2 - \phi_1)} \\ &= 2 + 2\cos(\phi_2 - \phi_1) = 2[1 + \cos(\phi_2 - \phi_1)] \\ &= 4\cos^2(\phi_2 - \phi_1). \end{aligned} \quad (7)$$

### Absolute Value

The absolute value of a REAL NUMBER  $x$  is denoted  $|x|$  and given by

$$|x| = x \operatorname{sgn}(x) = \begin{cases} -x & \text{for } x \leq 0 \\ x & \text{for } x \geq 0, \end{cases}$$

where  $\operatorname{SGN}$  is the sign function.

The same notation is used to denote the MODULUS of a COMPLEX NUMBER  $z = x + iy$ ,  $|z| \equiv \sqrt{x^2 + y^2}$ , a  $p$ -ADIC absolute value, or a general VALUATION. The NORM of a VECTOR  $\mathbf{x}$  is also denoted  $|\mathbf{x}|$ , although  $\|\mathbf{x}\|$  is more commonly used.

Other NOTATIONS similar to the absolute value are the FLOOR FUNCTION  $\lfloor x \rfloor$ , NINT function  $\operatorname{NINT}[x]$ , and CEILING FUNCTION  $\lceil x \rceil$ .

see also ABSOLUTE SQUARE, CEILING FUNCTION, FLOOR FUNCTION, MODULUS (COMPLEX NUMBER), NINT, SGN, TRIANGLE FUNCTION, VALUATION

### Absolutely Continuous

Let  $\mu$  be a POSITIVE MEASURE on a SIGMA ALGEBRA  $M$  and let  $\lambda$  be an arbitrary (real or complex) MEASURE on  $M$ . Then  $\lambda$  is absolutely continuous with respect to  $\mu$ , written  $\lambda \ll \mu$ , if  $\lambda(E) = 0$  for every  $E \in M$  for which  $\mu(E) = 0$ .

see also CONCENTRATED, MUTUALLY SINGULAR

### Absorption Law

The law appearing in the definition of a BOOLEAN ALGEBRA which states

$$a \wedge (a \vee b) = a \vee (a \wedge b) = a$$

for binary operators  $\vee$  and  $\wedge$  (which most commonly are logical OR and logical AND).

see also BOOLEAN ALGEBRA, LATTICE

### References

Birkhoff, G. and Mac Lane, S. *A Survey of Modern Algebra*, 3rd ed. New York: Macmillan, p. 317, 1965.

### Abstraction Operator

see LAMBDA CALCULUS

### Abundance

The abundance of a number  $n$  is the quantity

$$A(n) \equiv \sigma(n) - 2n,$$

where  $\sigma(n)$  is the DIVISOR FUNCTION. Kravitz has conjectured that no numbers exist whose abundance is an ODD SQUARE (Guy 1994).

The following table lists special classifications given to a number  $n$  based on the value of  $A(n)$ .

$A(n)$	Number
$< 0$	deficient number
$-1$	almost perfect number
$0$	perfect number
$1$	quasiperfect number
$> 0$	abundant number

see also DEFICIENCY

### References

Guy, R. K. *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 45–46, 1994.

### Abundant Number

An abundant number is an INTEGER  $n$  which is not a PERFECT NUMBER and for which

$$s(n) \equiv \sigma(n) - n > n, \quad (1)$$

where  $\sigma(n)$  is the DIVISOR FUNCTION. The quantity  $\sigma(n) - 2n$  is sometimes called the ABUNDANCE. The first few abundant numbers are 12, 18, 20, 24, 30, 36, ... (Sloane's A005101). Abundant numbers are sometimes called EXCESSIVE NUMBERS.

There are only 21 abundant numbers less than 100, and they are all EVEN. The first ODD abundant number is

$$945 = 3^3 \cdot 7 \cdot 5. \quad (2)$$

That 945 is abundant can be seen by computing

$$s(945) = 975 > 945. \quad (3)$$

Any multiple of a PERFECT NUMBER or an abundant number is also abundant. Every number greater than 20161 can be expressed as a sum of two abundant numbers.

Define the density function

$$A(x) \equiv \lim_{n \rightarrow \infty} \frac{|\{n : \sigma(n) \geq xn\}|}{n} \quad (4)$$

for a POSITIVE REAL NUMBER  $x$ , then Davenport (1933) proved that  $A(x)$  exists and is continuous for all  $x$ , and Erdős (1934) gave a simplified proof (Finch). Wall (1971) and Wall *et al.* (1977) showed that

$$0.2441 < A(2) < 0.2909, \quad (5)$$

and Deléglise showed that

$$0.2474 < A(2) < 0.2480. \quad (6)$$

A number which is abundant but for which all its PROPER DIVISORS are DEFICIENT is called a PRIMITIVE ABUNDANT NUMBER (Guy 1994, p. 46).

see also ALIQUOT SEQUENCE, DEFICIENT NUMBER, HIGHLY ABUNDANT NUMBER, MULTIAMICABLE NUMBERS, PERFECT NUMBER, PRACTICAL NUMBER, PRIMITIVE ABUNDANT NUMBER, WEIRD NUMBER

### Acceleration

Let a particle travel a distance  $s(t)$  as a function of time  $t$  (here,  $s$  can be thought of as the ARC LENGTH of the curve traced out by the particle). The SPEED (the SCALAR NORM of the VECTOR VELOCITY) is then given by

$$\frac{ds}{dt} = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2}. \quad (1)$$

The acceleration is defined as the time DERIVATIVE of the VELOCITY, so the SCALAR acceleration is given by

$$a \equiv \frac{dv}{dt} \quad (2)$$

$$= \frac{d^2s}{dt^2} \quad (3)$$

$$= \frac{\frac{dx}{dt} \frac{d^2x}{dt^2} + \frac{dy}{dt} \frac{d^2y}{dt^2} + \frac{dz}{dt} \frac{d^2z}{dt^2}}{\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2}} \quad (4)$$

$$= \frac{dx}{ds} \frac{d^2x}{dt^2} + \frac{dy}{ds} \frac{d^2y}{dt^2} + \frac{dz}{ds} \frac{d^2z}{dt^2} \quad (5)$$

$$= \frac{d\mathbf{r}}{ds} \cdot \frac{d^2\mathbf{r}}{dt^2}. \quad (6)$$

The VECTOR acceleration is given by

$$\mathbf{a} \equiv \frac{d\mathbf{v}}{dt} = \frac{d^2\mathbf{r}}{dt^2} = \frac{d^2s}{dt^2} \hat{\mathbf{T}} + \kappa \left(\frac{ds}{dt}\right)^2 \hat{\mathbf{N}}, \quad (7)$$

where  $\hat{\mathbf{T}}$  is the UNIT TANGENT VECTOR,  $\kappa$  the CURVATURE,  $s$  the ARC LENGTH, and  $\hat{\mathbf{N}}$  the UNIT NORMAL VECTOR.

Let a particle move along a straight LINE so that the positions at times  $t_1$ ,  $t_2$ , and  $t_3$  are  $s_1$ ,  $s_2$ , and  $s_3$ , respectively. Then the particle is uniformly accelerated with acceleration  $a$  IFF

$$a \equiv 2 \left[ \frac{(s_2 - s_3)t_1 + (s_3 - s_1)t_2 + (s_1 - s_2)t_3}{(t_1 - t_2)(t_2 - t_3)(t_3 - t_1)} \right] \quad (8)$$

is a constant (Klamkin 1995, 1996).

Consider the measurement of acceleration in a rotating reference frame. Apply the ROTATION OPERATOR

$$\tilde{R} \equiv \left( \frac{d}{dt} \right)_{\text{body}} + \omega \times \quad (9)$$

twice to the RADIUS VECTOR  $\mathbf{r}$  and suppress the *body* notation,

$$\begin{aligned} \mathbf{a}_{\text{space}} &= \tilde{R}^2 \mathbf{r} = \left( \frac{d}{dt} + \omega \times \right)^2 \mathbf{r} \\ &= \left( \frac{d}{dt} + \omega \times \right) \left( \frac{d\mathbf{r}}{dt} + \omega \times \mathbf{r} \right) \\ &= \frac{d^2 \mathbf{r}}{dt^2} + \frac{d}{dt} (\omega \times \mathbf{r}) + \omega \times \frac{d\mathbf{r}}{dt} + \omega \times (\omega \times \mathbf{r}) \\ &= \frac{d^2 \mathbf{r}}{dt^2} + \omega \times \frac{d\mathbf{r}}{dt} + \mathbf{r} \times \frac{d\omega}{dt} + \omega \times \frac{d\mathbf{r}}{dt} \\ &\quad + \omega \times (\omega \times \mathbf{r}). \end{aligned} \quad (10)$$

Grouping terms and using the definitions of the VELOCITY  $\mathbf{v} \equiv d\mathbf{r}/dt$  and ANGULAR VELOCITY  $\boldsymbol{\alpha} \equiv d\omega/dt$  give the expression

$$\mathbf{a}_{\text{space}} = \frac{d^2 \mathbf{r}}{dt^2} + 2\omega \times \mathbf{v} + \omega \times (\omega \times \mathbf{r}) + \mathbf{r} \times \boldsymbol{\alpha}. \quad (11)$$

Now, we can identify the expression as consisting of three terms

$$\mathbf{a}_{\text{body}} \equiv \frac{d^2 \mathbf{r}}{dt^2}, \quad (12)$$

$$\mathbf{a}_{\text{Coriolis}} \equiv 2\omega \times \mathbf{v}, \quad (13)$$

$$\mathbf{a}_{\text{centrifugal}} \equiv \omega \times (\omega \times \mathbf{r}), \quad (14)$$

a “body” acceleration, centrifugal acceleration, and Coriolis acceleration. Using these definitions finally gives

$$\mathbf{a}_{\text{space}} = \mathbf{a}_{\text{body}} + \mathbf{a}_{\text{Coriolis}} + \mathbf{a}_{\text{centrifugal}} + \mathbf{r} \times \boldsymbol{\alpha}, \quad (15)$$

where the fourth term will vanish in a uniformly rotating frame of reference (i.e.,  $\boldsymbol{\alpha} = 0$ ). The centrifugal acceleration is familiar to riders of merry-go-rounds, and the Coriolis acceleration is responsible for the motions of hurricanes on Earth and necessitates large trajectory corrections for intercontinental ballistic missiles.

#### Achilles and the Tortoise Paradox

see ZENO’S PARADOXES

#### Ackermann Function

The Ackermann function is the simplest example of a well-defined TOTAL FUNCTION which is COMPUTABLE but not PRIMITIVE RECURSIVE, providing a counterexample to the belief in the early 1900s that every COMPUTABLE FUNCTION was also PRIMITIVE RECURSIVE (Dötzel 1991). It grows faster than an exponential function, or even a multiple exponential function. The Ackermann function  $A(x, y)$  is defined by

$$A(x, y) \equiv \begin{cases} y + 1 & \text{if } x = 0 \\ A(x - 1, 1) & \text{if } y = 0 \\ A(x - 1, A(x, y - 1)) & \text{otherwise.} \end{cases} \quad (1)$$

Special values for INTEGER  $x$  include

$$A(0, y) = y + 1 \quad (2)$$

$$A(1, y) = y + 2 \quad (3)$$

$$A(2, y) = 2y + 3 \quad (4)$$

$$A(3, y) = 2^{y+3} - 3 \quad (5)$$

$$A(4, y) = \underbrace{2^{2^{\dots^2}}}_{y+3} - 3. \quad (6)$$

Expressions of the latter form are sometimes called POWER TOWERS.  $A(0, y)$  follows trivially from the definition.  $A(1, y)$  can be derived as follows,

$$\begin{aligned} A(1, y) &= A(0, A(1, y - 1)) = A(1, y - 1) + 1 \\ &= A(0, A(1, y - 2)) + 1 = A(1, y - 2) + 2 \\ &= \dots = A(1, 0) + y = A(0, 1) + y = y + 2. \end{aligned} \quad (7)$$

$A(2, y)$  has a similar derivation,

$$\begin{aligned} A(2, y) &= A(1, A(2, y - 1)) = A(2, y - 1) + 2 \\ &= A(1, A(2, y - 2)) + 2 = A(2, y - 2) + 4 = \dots \\ &= A(2, 0) + 2y = A(1, 1) + 2y = 2y + 3. \end{aligned} \quad (8)$$

Buck (1963) defines a related function using the same fundamental RECURRENCE RELATION (with arguments flipped from Buck’s convention)

$$F(x, y) = F(x - 1, F(x, y - 1)), \quad (9)$$

see also ACKERMANN FUNCTION, ARROW NOTATION,  
POWER TOWER

$$F(1, 0) = 2 \quad (11)$$

$$F(2, 0) = 0 \quad (12)$$

$$F(x, 0) = 1 \quad \text{for } x = 3, 4, \dots \quad (13)$$

$$F(x, 0) = 1 \quad \text{for } x = 3, 4, \dots \quad (13)$$

$$F(1, y) = 2 + y \quad (14)$$

$$F(2, y) = 2y \quad (15)$$

$$F(3, y) = 2^y \quad (16)$$

$$F(4, y) = \underbrace{2^2}_{y^2} \overset{2}{\dots}. \quad (17)$$

then gives  $1, 3, 4, 8, 65536, \underbrace{2^{2^m}}_m, \dots$  (Sloane's A001695),

where  $m = \underbrace{2^{2^{\dots^2}}}_{65536}$ , a truly huge number!

A term invented by B. Grünbaum in an attempt to promote concrete and precise POLYHEDRON terminology. The word "coptic" derives from the Greek for "to cut," and acoptic polyhedra are defined as POLYHEDRA for which the FACES do not intersect (cut) themselves, making them 2-MANIFOLDS.

*see also* HONEYCOMB, NOLID, POLYHEDRON, SPONGE

Let  $M(X)$  denote the GROUP of all invertible MAPS  $X \rightarrow X$  and let  $G$  be any GROUP. A HOMOMORPHISM  $\theta : G \rightarrow M(X)$  is called an action of  $G$  on  $X$ . Therefore,  $\theta$  satisfies

1. For each  $g \in G$ ,  $\theta(g)$  is a MAP  $X \rightarrow X : x \mapsto \theta(g)x$ ,
2.  $\theta(gh)x = \theta(g)(\theta(h)x)$ ,
3.  $\theta(e)x = x$ , where  $e$  is the group identity in  $G$ ,
4.  $\theta(q^{-1})x = \theta(q)^{-1}x$ .

STRAIGHT ANGLE

A TRIANGLE in which all three ANGLES are ACUTE ANGLES. A TRIANGLE which is neither acute nor a RIGHT TRIANGLE (i.e., it has an OBTUSE ANGLE) is called an OBTUSE TRIANGLE. A SQUARE can be dissected into as few as 8 acute triangles.

*see also* OBTUSE TRIANGLE, RIGHT TRIANGLE

## Adams-Bashforth-Moulton Method

see ADAMS' METHOD

### Adams' Method

Adams' method is a numerical METHOD for solving linear FIRST-ORDER ORDINARY DIFFERENTIAL EQUATIONS of the form

$$\frac{dy}{dx} = f(x, y). \quad (1)$$

Let

$$h = x_{n+1} - x_n \quad (2)$$

be the step interval, and consider the MACLAURIN SERIES of  $y$  about  $x_n$ ,

$$y_{n+1} = y_n + \left(\frac{dy}{dx}\right)_n (x - x_n) + \frac{1}{2} \left(\frac{d^2y}{dx^2}\right)_n (x - x_n)^2 + \dots \quad (3)$$

$$\left(\frac{dy}{dx}\right)_{n+1} = \left(\frac{dy}{dx}\right)_n + \left(\frac{d^2y}{dx^2}\right)_n (x - x_n) + \dots \quad (4)$$

Here, the DERIVATIVES of  $y$  are given by the BACKWARD DIFFERENCES

$$q_n \equiv \left(\frac{dy}{dx}\right)_n = \frac{\Delta y_n}{x_{n+1} - x_n} = \frac{y_{n+1} - y_n}{h} \quad (5)$$

$$\nabla q_n \equiv \left(\frac{d^2y}{dx^2}\right)_n = q_n - q_{n-1} \quad (6)$$

$$\nabla^2 q_n \equiv \left(\frac{d^3y}{dx^3}\right)_n = \nabla q_n - \nabla q_{n-1}, \quad (7)$$

etc. Note that by (1),  $q_n$  is just the value of  $f(x_n, y_n)$ .

For first-order interpolation, the method proceeds by iterating the expression

$$y_{n+1} = y_n + q_n h \quad (8)$$

where  $q_n \equiv f(x_n, y_n)$ . The method can then be extended to arbitrary order using the finite difference integration formula from Beyer (1987)

$$\int_0^1 f_p dp = \left(1 + \frac{1}{2} \nabla + \frac{5}{12} \nabla^2 + \frac{3}{8} \nabla^3 + \frac{251}{720} \nabla^4 + \frac{95}{288} \nabla^5 + \frac{19087}{60480} \nabla^6 + \dots\right) f_p \quad (9)$$

to obtain

$$y_{n+1} - y_n = h \left( q_n + \frac{1}{2} \nabla q_{n-1} + \frac{5}{12} \nabla^2 q_{n-2} + \frac{3}{8} \nabla^3 q_{n-3} + \frac{251}{720} \nabla^4 q_{n-4} + \frac{95}{288} \nabla^5 q_{n-5} + \dots \right). \quad (10)$$

Note that von Kármán and Biot (1940) confusingly use the symbol normally used for FORWARD DIFFERENCES  $\Delta$  to denote BACKWARD DIFFERENCES  $\nabla$ .

see also GILL'S METHOD, MILNE'S METHOD, PREDICTOR-CORRECTOR METHODS, RUNGE-KUTTA METHOD

### Addend

A quantity to be ADDED to another, also called a SUMMAND. For example, in the expression  $a + b + c$ ,  $a$ ,  $b$ , and  $c$  are all addends. The first of several addends, or "the one to which the others are added" ( $a$  in the previous example), is sometimes called the AUGEND.

see also ADDITION, AUGEND, PLUS, RADICAND

### Addition

$$\begin{array}{r} 1 \ 1 \quad \leftarrow \text{carries} \\ 1 \ 5 \ 8 \quad \leftarrow \text{addend 1} \\ + 2 \ 4 \ 9 \quad \leftarrow \text{addend 2} \\ \hline 4 \ 0 \ 7 \quad \leftarrow \text{sum} \end{array}$$

The combining of two or more quantities using the PLUS operator. The individual numbers being combined are called ADDENDS, and the total is called the SUM. The first of several ADDENDS, or "the one to which the others are added," is sometimes called the AUGEND. The opposite of addition is SUBTRACTION.

While the usual form of adding two  $n$ -digit INTEGERS (which consists of summing over the columns right to left and "CARRYING" a 1 to the next column if the sum exceeds 9) requires  $n$  operations (plus carries), two  $n$ -digit INTEGERS can be added in about  $2 \lg n$  steps by  $n$  processors using carry-lookahead addition (McGeoch 1993). Here,  $\lg x$  is the LG function, the LOGARITHM to the base 2.

### Addition Chain

An addition chain for a number  $n$  is a SEQUENCE  $1 = a_0 < a_1 < \dots < a_r = n$ , such that each member after  $a_0$  is the SUM of the two earlier (not necessarily distinct) ones. The number  $r$  is called the length of the addition chain. For example,

$$1, 1 + 1 = 2, 2 + 2 = 4, 4 + 2 = 6, 6 + 2 = 8, 8 + 6 = 14$$

[illegible]

Guy, R. K. "Addition Chains. Brauer Chains. Hansen Chains." §C6 in *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 111–113, 1994.

It is conjectured that the maximum number lacking the DIGIT 1 with persistence 11 is

Consider the process of taking a number, adding its DIGITS, then adding the DIGITS of number derived from it, etc., until the remaining number has only one DIGIT. The number of additions required to obtain a single DIGIT from a number  $n$  is called the additive persistence of  $n$ , and the DIGIT obtained is called the DIGITAL ROOT of  $n$ .

There is a stronger conjecture that there is a maximum number lacking the DIGIT 1 for each persistence  $\geq 2$ .

The maximum additive persistence in base 2 is 1. It is conjectured that all powers of  $2 > 2^{15}$  contain a 0 in base 3, which would imply that the maximum persistence in base 3 is 3 (Guy, 1994).

An element of an ADÉLE GROUP, sometimes called a REPARTITION in older literature. Adèles arise in both NUMBER FIELDS and FUNCTION FIELDS. The adèles of a NUMBER FIELD are the additive SUBGROUPS of all elements in  $\prod k_\nu$ , where  $\nu$  is the PLACE, whose ABSOLUTE VALUE is  $< 1$  at all but finitely many  $\nu$ s.

Let  $F$  be a FUNCTION FIELD of algebraic functions of one variable. Then a MAP  $r$  which assigns to every PLACE  $P$  of  $F$  an element  $r(P)$  of  $F$  such that there are only a finite number of PLACES  $P$  for which  $\nu_P(r(P)) < 0$ .

The restricted topological DIRECT PRODUCT of the GROUP  $G_{k_v}$  with distinct invariant open subgroups  $G_{0_v}$ .

Weil, A. *Adèles and Algebraic Groups*. Princeton, NJ: Princeton University Press, 1961.

### Adem Relations

Relations in the definition of a STEENROD ALGEBRA which state that, for  $i < 2j$ ,

$$Sq^i \circ Sq^j(x) = \sum_{k=0}^{[i]} \binom{j-k-1}{i-2k} Sq^{i+j-k} \circ Sq^k(x),$$

where  $f \circ g$  denotes function COMPOSITION and  $[i]$  is the FLOOR FUNCTION.

see also STEENROD ALGEBRA

### Adequate Knot

A class of KNOTS containing the class of ALTERNATING KNOTS. Let  $c(K)$  be the CROSSING NUMBER. Then for KNOT SUM  $K_1 \# K_2$  which is an adequate knot,

$$c(K_1 \# K_2) = c(K_1) + c(K_2).$$

This relationship is postulated to hold true for all KNOTS.

see also ALTERNATING KNOT, CROSSING NUMBER (LINK)

### Adiabatic Invariant

A property of motion which is conserved to exponential accuracy in the small parameter representing the typical rate of change of the gross properties of the body.

see also ALGEBRAIC INVARIANT, LYAPUNOV CHARACTERISTIC NUMBER

### Adjacency Matrix

The adjacency matrix of a simple GRAPH is a MATRIX with rows and columns labelled by VERTICES, with a 1 or 0 in position  $(v_i, v_j)$  according to whether  $v_i$  and  $v_j$  are ADJACENT or not.

see also INCIDENCE MATRIX

#### References

Chartrand, G. *Introductory Graph Theory*. New York: Dover, p. 218, 1985.

### Adjacency Relation

The SET  $E$  of EDGES of a GRAPH  $(V, E)$ , being a set of unordered pairs of elements of  $V$ , constitutes a RELATION on  $V$ . Formally, an adjacency relation is any RELATION which is IRREFLEXIVE and SYMMETRIC.

see also IRREFLEXIVE, RELATION, SYMMETRIC

### Adjacent Fraction

Two FRACTIONS are said to be adjacent if their difference has a unit NUMERATOR. For example,  $1/3$  and  $1/4$  are adjacent since  $1/3 - 1/4 = 1/12$ , but  $1/2$  and  $1/5$  are not since  $1/2 - 1/5 = 3/10$ . Adjacent fractions can be adjacent in a FAREY SEQUENCE.

see also FAREY SEQUENCE, FORD CIRCLE, FRACTION, NUMERATOR

#### References

Pickover, C. A. *Keys to Infinity*. New York: W. H. Freeman, p. 119, 1995.

### Adjacent Value

The value nearest to but still inside an inner FENCE.

#### References

Tukey, J. W. *Explanatory Data Analysis*. Reading, MA: Addison-Wesley, p. 667, 1977.

### Adjacent Vertices

In a GRAPH  $G$ , two VERTICES are adjacent if they are joined by an EDGE.

### Adjoint Curve

A curve which has at least multiplicity  $r_i - 1$  at each point where a given curve (having only ordinary singular points and cusps) has a multiplicity  $r_i$  is called the adjoint to the given curve. When the adjoint curve is of order  $n - 3$ , it is called a special adjoint curve.

#### References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 30, 1959.

### Adjoint Matrix

The adjoint matrix, sometimes also called the ADJUGATE MATRIX, is defined by

$$A^\dagger \equiv (A^T)^*, \quad (1)$$

where the ADJOINT OPERATOR is denoted  $^\dagger$  and  $^T$  denotes the TRANSPOSE. If a MATRIX is SELF-ADJOINT, it is said to be HERMITIAN. The adjoint matrix of a MATRIX product is given by

$$(ab)^\dagger_{ij} = [(ab)^T]^\dagger_{ij}. \quad (2)$$

Using the property of transpose products that

$$\begin{aligned} [(ab)^T]^\dagger_{ij} &= (b^T a^T)^\dagger_{ij} = (b_{ik}^T a_{kj}^T)^* = (b^T)_{ik}^* (a^T)_{kj}^* \\ &= b_{ik}^\dagger a_{kj}^\dagger = (b^\dagger a^\dagger)_{ij}, \end{aligned} \quad (3)$$

it follows that

$$(AB)^\dagger = B^\dagger A^\dagger. \quad (4)$$

### Adjoint Operator

Given a SECOND-ORDER ORDINARY DIFFERENTIAL EQUATION

$$\tilde{\mathcal{L}}u(x) \equiv p_0 \frac{du^2}{dx^2} + p_1 \frac{du}{dx} + p_2 u, \quad (1)$$

where  $p_i \equiv p_i(x)$  and  $u \equiv u(x)$ , the adjoint operator  $\tilde{\mathcal{L}}^\dagger$  is defined by

$$\begin{aligned} \tilde{\mathcal{L}}^\dagger u &\equiv \frac{d}{dx^2}(p_0 u) - \frac{d}{dx}(p_1 u) + p_2 u \\ &= p_0 \frac{d^2 u}{dx^2} + (2p_0' - p_1) \frac{du}{dx} + (p_0'' - p_1' + p_2)u. \end{aligned} \quad (2)$$

Write the two LINEARLY INDEPENDENT solutions as  $y_1(x)$  and  $y_2(x)$ . Then the adjoint operator can also be written

$$\tilde{\mathcal{L}}^{\dagger}u = \int (y_2\tilde{\mathcal{L}}y_1 - y_1\tilde{\mathcal{L}}y_2) dx = \left[ \frac{p_1}{p_0}(y_1'y_2 - y_1y_2') \right]. \quad (3)$$

see also SELF-ADJOINT OPERATOR, STURM-LIOUVILLE THEORY

## Adjugate Matrix

see ADJOINT MATRIX

## Adjunction

If  $a$  is an element of a FIELD  $F$  over the PRIME FIELD  $P$ , then the set of all RATIONAL FUNCTIONS of  $a$  with COEFFICIENTS in  $P$  is a FIELD derived from  $P$  by adjunction of  $a$ .

## Adleman-Pomerance-Rumely Primality Test

A modified MILLER'S PRIMALITY TEST which gives a guarantee of PRIMALITY or COMPOSITENESS. The ALGORITHM's running time for a number  $N$  has been proved to be as  $\mathcal{O}((\ln N)^{c \ln \ln \ln N})$  for some  $c > 0$ . It was simplified by Cohen and Lenstra (1984), implemented by Cohen and Lenstra (1987), and subsequently optimized by Bosma and van der Hulst (1990).

## Affine Hull

The IDEAL generated by a SET in a VECTOR SPACE.

see also AFFINE COMPLEX PLANE, AFFINE CONNECTION, AFFINE EQUATION, AFFINE GEOMETRY, AFFINE GROUP, AFFINE PLANE, AFFINE SPACE, AFFINE TRANSFORMATION, AFFINITY, CONVEX HULL, HULL

### Affine Plane

A 2-D AFFINE GEOMETRY constructed over a FINITE FIELD. For a FIELD  $F$  of size  $n$ , the affine plane consists of the set of points which are ordered pairs of elements in  $F$  and a set of lines which are themselves a set of points. Adding a POINT AT INFINITY and LINE AT INFINITY allows a PROJECTIVE PLANE to be constructed from an affine plane. An affine plane of order  $n$  is a BLOCK DESIGN of the form  $(n^2, n, 1)$ . An affine plane of order  $n$  exists IFF a PROJECTIVE PLANE of order  $n$  exists.

### Affine Space

Let  $V$  be a VECTOR SPACE over a FIELD  $K$ , and let  $A$  be a nonempty SET. Now define addition  $p + a \in A$  for any VECTOR  $a \in V$  and element  $p \in A$  subject to the conditions

1.  $p + 0 = p$ ,
2.  $(p + a) + b = p + (a + b)$ ,
3. For any  $q \in A$ , there EXISTS a unique VECTOR  $a \in V$  such that  $q = p + a$ .

Here,  $a, b \in V$ . Note that (1) is implied by (2) and (3). Then  $A$  is an affine space and  $K$  is called the COEFFICIENT FIELD.

In an affine space, it is possible to fix a point and coordinate axis such that every point in the SPACE can be represented as an  $n$ -tuple of its coordinates. Every ordered pair of points  $A$  and  $B$  in an affine space is then associated with a VECTOR  $AB$ .

see also AFFINE COMPLEX PLANE, AFFINE CONNECTION, AFFINE EQUATION, AFFINE GEOMETRY, AFFINE GROUP, AFFINE HULL, AFFINE PLANE, AFFINE SPACE, AFFINE TRANSFORMATION, AFFINITY

### Affine Transformation

Any TRANSFORMATION preserving COLLINEARITY (i.e., all points lying on a LINE initially still lie on a LINE after TRANSFORMATION). An affine transformation is also called an AFFINITY. An affine transformation of  $\mathbb{R}^n$  is a MAP  $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$  of the form

$$F(p) = Ap + q \quad (1)$$

for all  $p \in \mathbb{R}^n$ , where  $A$  is a linear transformation of  $\mathbb{R}^n$ . If  $\det(A) = 1$ , the transformation is ORIENTATION-PRESERVING; if  $\det(A) = -1$ , it is ORIENTATION-REVERSING.

DILATION (CONTRACTION, HOMOTHECY), EXPANSION, REFLECTION, ROTATION, and TRANSLATION are all affine transformations, as are their combinations. A particular example combining ROTATION and EXPANSION is the rotation-enlargement transformation

$$\begin{aligned} \begin{bmatrix} x' \\ y' \end{bmatrix} &= s \begin{bmatrix} \cos \alpha & \sin \alpha \\ -\sin \alpha & \cos \alpha \end{bmatrix} \begin{bmatrix} x - x_0 \\ y - y_0 \end{bmatrix} \\ &= s \begin{bmatrix} \cos \alpha (x - x_0) + \sin \alpha (y - y_0) \\ -\sin \alpha (x - x_0) + \cos \alpha (y - y_0) \end{bmatrix}. \end{aligned} \quad (2)$$

Separating the equations,

$$x' = (s \cos \alpha)x + (s \sin \alpha)y - s(x_0 \cos \alpha + y_0 \sin \alpha) \quad (3)$$

$$y' = (-s \sin \alpha)x + (s \cos \alpha)y + s(x_0 \sin \alpha - y_0 \cos \alpha). \quad (4)$$

This can be also written as

$$x' = ax + by + c \quad (5)$$

$$y' = bx + ay + d, \quad (6)$$

where

$$a = s \cos \alpha \quad (7)$$

$$b = -s \sin \alpha. \quad (8)$$

The scale factor  $s$  is then defined by

$$s \equiv \sqrt{a^2 + b^2}, \quad (9)$$

and the rotation ANGLE by

$$\alpha = \tan^{-1} \left( -\frac{b}{a} \right). \quad (10)$$

**Airy Differential Equation**

Some authors define a general Airy differential equation as

$$y'' \pm k^2 xy = 0. \quad (1)$$

This equation can be solved by series solution using the expansions

$$y = \sum_{n=0}^{\infty} a_n x^n \quad (2)$$

$$\begin{aligned} y' &= \sum_{n=0}^{\infty} n a_n x^{n-1} = \sum_{n=1}^{\infty} n a_n x^{n-1} \\ &= \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n \end{aligned} \quad (3)$$

$$\begin{aligned} y'' &= \sum_{n=0}^{\infty} (n+1) n a_{n+1} x^{n-1} = \sum_{n=1}^{\infty} (n+1) n a_{n+1} x^{n-1} \\ &= \sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n. \end{aligned} \quad (4)$$

Specializing to the "conventional" Airy differential equation occurs by taking the MINUS SIGN and setting  $k^2 = 1$ . Then plug (4) into

$$y'' - xy = 0 \quad (5)$$

to obtain

$$\sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n - x \sum_{n=0}^{\infty} a_n x^n = 0 \quad (6)$$

$$\sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n - \sum_{n=0}^{\infty} a_n x^{n+1} = 0 \quad (7)$$

$$2a_2 + \sum_{n=1}^{\infty} (n+2)(n+1) a_{n+2} x^n - \sum_{n=1}^{\infty} a_{n-1} x^n = 0 \quad (8)$$

$$2a_2 + \sum_{n=1}^{\infty} [(n+2)(n+1) a_{n+2} - a_{n-1}] x^n = 0. \quad (9)$$

In order for this equality to hold for all  $x$ , each term must separately be 0. Therefore,

$$a_2 = 0 \quad (10)$$

$$(n+2)(n+1) a_{n+2} = a_{n-1}. \quad (11)$$

Starting with the  $n = 3$  term and using the above RECURRENCE RELATION, we obtain

$$5 \cdot 4 a_5 = 20 a_5 = a_2 = 0. \quad (12)$$

Continuing, it follows by INDUCTION that

$$a_2 = a_5 = a_8 = a_{11} = \dots a_{3n-1} = 0 \quad (13)$$

for  $n = 1, 2, \dots$ . Now examine terms of the form  $a_{3n}$ .

$$a_3 = \frac{a_0}{3 \cdot 2} \quad (14)$$

$$a_6 = \frac{a_3}{6 \cdot 5} = \frac{a_0}{(6 \cdot 5)(3 \cdot 2)} \quad (15)$$

$$a_9 = \frac{a_6}{9 \cdot 8} = \frac{a_0}{(9 \cdot 8)(6 \cdot 5)(3 \cdot 2)}. \quad (16)$$

Again by INDUCTION,

$$a_{3n} = \frac{a_0}{[(3n)(3n-1)][(3n-3)(3n-4)] \dots [6 \cdot 5][3 \cdot 2]} \quad (17)$$

for  $n = 1, 2, \dots$ . Finally, look at terms of the form  $a_{3n+1}$ ,

$$a_4 = \frac{a_1}{4 \cdot 3} \quad (18)$$

$$a_7 = \frac{a_4}{7 \cdot 6} = \frac{a_1}{(7 \cdot 6)(4 \cdot 3)} \quad (19)$$

$$a_{10} = \frac{a_7}{10 \cdot 9} = \frac{a_1}{(10 \cdot 9)(7 \cdot 6)(4 \cdot 3)}. \quad (20)$$

By INDUCTION,

$$a_{3n+1} = \frac{a_1}{[(3n+1)(3n)][(3n-2)(3n-3)] \cdots [7 \cdot 6][4 \cdot 3]} \quad (21)$$

for  $n = 1, 2, \dots$ . The general solution is therefore

$$y = a_0 \left[ 1 + \sum_{n=1}^{\infty} \frac{x^{3n}}{(3n)(3n-1)(3n-3)(3n-4) \cdots 3 \cdot 2} \right] + a_1 \left[ x + \sum_{n=1}^{\infty} \frac{x^{3n+1}}{(3n+1)(3n)(3n-2)(3n-3) \cdots 4 \cdot 3} \right]. \quad (22)$$

For a general  $k^2$  with a MINUS SIGN, equation (1) is

$$y'' - k^2 xy = 0, \quad (23)$$

and the solution is

$$y(x) = \frac{1}{3} \sqrt{x} \left[ AI_{-1/3} \left( \frac{2}{3} kx^{3/2} \right) - BI_{1/3} \left( \frac{2}{3} kx^{3/2} \right) \right], \quad (24)$$

where  $I$  is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND. This is usually expressed in terms of the AIRY FUNCTIONS  $Ai(x)$  and  $Bi(x)$

$$y(x) = A' Ai(k^{2/3}x) + B' Bi(k^{2/3}x). \quad (25)$$

If the PLUS SIGN is present instead, then

$$y'' + k^2 xy = 0 \quad (26)$$

and the solutions are

$$y(x) = \frac{1}{3} \sqrt{x} \left[ AJ_{-1/3} \left( \frac{2}{3} kx^{3/2} \right) + BJ_{1/3} \left( \frac{2}{3} kx^{3/2} \right) \right], \quad (27)$$

where  $J(z)$  is a BESSEL FUNCTION OF THE FIRST KIND. see also AIRY-FOCK FUNCTIONS, AIRY FUNCTIONS, BESSEL FUNCTION OF THE FIRST KIND, MODIFIED BESSEL FUNCTION OF THE FIRST KIND

## Airy-Fock Functions

The three Airy-Fock functions are

$$\nu(z) = \frac{1}{2} \sqrt{\pi} Ai(z) \quad (1)$$

$$w_1(z) = 2e^{i\pi/6} \nu(\omega z) \quad (2)$$

$$w_2(z) = 2e^{-i\pi/6} \nu(\omega^{-1}z), \quad (3)$$

where  $Ai(z)$  is an AIRY FUNCTION. These functions satisfy

$$\nu(z) = \frac{w_1(z) - w_2(z)}{2i} \quad (4)$$

$$[w_1(z)]^* = w_2(z^*), \quad (5)$$

where  $z^*$  is the COMPLEX CONJUGATE of  $z$ .

## Airy Functions

Watson's (1966, pp. 188–190) definition of an Airy function is the solution to the AIRY DIFFERENTIAL EQUATION

$$\Phi'' \pm k^2 \Phi x = 0 \quad (1)$$

which is FINITE at the ORIGIN, where  $\Phi'$  denotes the DERIVATIVE  $d\Phi/dx$ ,  $k^2 = 1/3$ , and either SIGN is permitted. Call these solutions  $(1/\pi)\Phi(\pm k^2, x)$ , then

$$\frac{1}{\pi} \Phi(\pm \frac{1}{3}; x) \equiv \int_0^\infty \cos(t^3 \pm xt) dt \quad (2)$$

$$\Phi(\frac{1}{3}; x) = \frac{1}{3} \pi \sqrt{\frac{x}{3}} \left[ J_{-1/3} \left( \frac{2x^{3/2}}{3^{3/2}} \right) + J_{1/3} \left( \frac{2x^{3/2}}{3^{3/2}} \right) \right] \quad (3)$$

$$\Phi(-\frac{1}{3}; x) = \frac{1}{3} \pi \sqrt{\frac{x}{3}} \left[ I_{-1/3} \left( \frac{2x^{3/2}}{3^{3/2}} \right) - I_{1/3} \left( \frac{2x^{3/2}}{3^{3/2}} \right) \right], \quad (4)$$

where  $J(z)$  is a BESSEL FUNCTION OF THE FIRST KIND and  $I(z)$  is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND. Using the identity

$$K_n(x) = \frac{\pi I_{-n}(x) - I_n(x)}{2 \sin(n\pi)}, \quad (5)$$

where  $K(z)$  is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND, the second case can be re-expressed

$$\Phi(-\frac{1}{3}; x) = \frac{1}{3} \pi \sqrt{\frac{x}{3}} \left( \frac{2}{\pi} \right) \sin \left( \frac{1}{3} \pi \right) K_{1/3} \left( \frac{2x^{3/2}}{3^{3/2}} \right) \quad (6)$$

$$= \frac{\pi}{3} \sqrt{\frac{1}{3}x} \frac{2}{\pi} \frac{\sqrt{3}}{2} K_{1/3} \left( \frac{2x^{3/2}}{3^{3/2}} \right) \quad (7)$$

$$= \frac{1}{3} \sqrt{x} K_{1/3} \left( \frac{2x^{3/2}}{3^{3/2}} \right). \quad (8)$$

A more commonly used definition of Airy functions is given by Abramowitz and Stegun (1972, pp. 446–447) and illustrated above. This definition identifies the  $Ai(x)$  and  $Bi(x)$  functions as the two LINEARLY INDEPENDENT solutions to (1) with  $k^2 = 1$  and a MINUS SIGN,

$$y'' - yz = 0. \quad (9)$$

The solutions are then written

$$y(z) = A \text{Ai}(z) + B \text{Bi}(z), \quad (10)$$

where

$$\begin{aligned} \text{Ai}(z) &= \frac{1}{\pi} \Phi(-1, z) \\ &= \frac{1}{3} \sqrt{x} [I_{-1/3}(\frac{2}{3}z^{3/2}) - I_{1/3}(\frac{2}{3}z^{3/2})] \\ &= \sqrt{\frac{z}{3\pi}} K_{1/3}(\frac{2}{3}z^{3/2}) \end{aligned} \quad (11)$$

$$\text{Bi}(z) \equiv \sqrt{\frac{z}{3}} [I_{-1/3}(\frac{2}{3}z^{3/2}) + I_{1/3}(\frac{2}{3}z^{3/2})]. \quad (12)$$

In the above plot,  $\text{Ai}(z)$  is the solid curve and  $\text{Bi}(z)$  is dashed. For zero argument,

$$\text{Ai}(0) = -\frac{3^{-2/3}}{\Gamma(\frac{2}{3})}, \quad (13)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION. This means that Watson's expression becomes

$$(3a)^{-1/3} \pi \text{Ai}(\pm(3a)^{-1/3}x) = \int_0^\infty \cos(at^3 \pm xt) dt. \quad (14)$$

A generalization has been constructed by Hardy.

The ASYMPTOTIC SERIES of  $\text{Ai}(z)$  has a different form in different QUADRANTS of the COMPLEX PLANE, a fact known as the STOKES PHENOMENON. Functions related to the Airy functions have been defined as

$$\text{Gi}(z) \equiv \frac{1}{\pi} \int_0^\infty \sin(\frac{1}{3}t^3 + zt) dt \quad (15)$$

$$\text{Hi}(z) \equiv \frac{1}{\pi} \int_0^\infty \exp(-\frac{1}{3}t^3 + zt) dt. \quad (16)$$

### Airy Projection

A MAP PROJECTION. The inverse equations for  $\phi$  are computed by iteration. Let the ANGLE of the projection plane be  $\theta_b$ . Define

$$a = \begin{cases} 0 & \text{for } \theta_b = \frac{1}{2}\pi \\ \frac{\ln[\frac{1}{2} \cos(\frac{1}{2}\pi - \theta_b)]}{\tan[\frac{1}{2}(\frac{1}{2}\pi - \theta_b)]} & \text{otherwise.} \end{cases} \quad (1)$$

For proper convergence, let  $x_i = \pi/6$  and compute the initial point by checking

$$x_i = \left| \exp[-(\sqrt{x^2 + y^2} + a \tan x_i) \tan x_i] \right|. \quad (2)$$

As long as  $x_i > 1$ , take  $x_{i+1} = x_i/2$  and iterate again. The first value for which  $x_i < 1$  is then the starting point. Then compute

$$x_i = \cos^{-1}\{\exp[-(\sqrt{x^2 + y^2} + a \tan x_i) \tan x_i]\} \quad (3)$$

until the change in  $x_i$  between evaluations is smaller than the acceptable tolerance. The (inverse) equations are then given by

$$\phi = \frac{1}{2}\pi - 2x_i \quad (4)$$

$$\lambda = \tan^{-1}\left(-\frac{x}{y}\right). \quad (5)$$

### Aitken's $\delta^2$ Process

AN ALGORITHM which extrapolates the partial sums  $s_n$  of a SERIES  $\sum_n a_n$  whose CONVERGENCE is approximately geometric and accelerates its rate of CONVERGENCE. The extrapolated partial sum is given by

$$s_n' \equiv s_{n+1} - \frac{(s_{n+1} - s_n)^2}{s_{n+1} - 2s_n + s_{n-1}}.$$

### Aitken Interpolation

An algorithm similar to NEVILLE'S ALGORITHM for constructing the LAGRANGE INTERPOLATING POLYNOMIAL. Let  $f(x|x_0, x_1, \dots, x_k)$  be the unique POLYNOMIAL of  $k$ th ORDER coinciding with  $f(x)$  at  $x_0, \dots, x_k$ . Then

$$f(x|x_0, x_1) = \frac{1}{x_1 - x_0} \begin{vmatrix} f_0 & x_0 - x \\ f_1 & x_1 - x \end{vmatrix}$$

$$f(x|x_0, x_2) = \frac{1}{x_2 - x_0} \begin{vmatrix} f_0 & x_0 - x \\ f_2 & x_2 - x \end{vmatrix}$$

$$f(x|x_0, x_1, x_2) = \frac{1}{x_2 - x_1} \begin{vmatrix} f(x|x_0, x_1) & x_1 - x \\ f(x|x_0, x_2) & x_2 - x \end{vmatrix}$$

$$f(x|x_0, x_1, x_2, x_3) = \frac{1}{x_3 - x_2} \begin{vmatrix} f(x|x_0, x_1, x_2) & x_2 - x \\ f(x|x_0, x_1, x_3) & x_3 - x \end{vmatrix}.$$

### Ajima-Malfatti Points

The lines connecting the vertices and corresponding circle-circle intersections in MALFATTI'S TANGENT TRIANGLE PROBLEM coincide in a point  $Y$  called the first Ajima-Malfatti point (Kimberling and MacDonald 1990, Kimberling 1994). Similarly, letting  $A''$ ,  $B''$ , and  $C''$  be the excenters of  $ABC$ , then the lines  $A'A''$ ,  $B'B''$ , and  $C'C''$  are coincident in another point called the second Ajima-Malfatti point. The points are sometimes simply called the MALFATTI POINTS (Kimberling 1994).

### Albers Conic Projection

see ALBERS EQUAL-AREA CONIC PROJECTION

### Albers Equal-Area Conic Projection

Let  $\phi_0$  be the LATITUDE for the origin of the CARTESIAN COORDINATES and  $\lambda_0$  its LONGITUDE. Let  $\phi_1$  and  $\phi_2$  be the standard parallels. Then

$$x = \rho \sin \theta \quad (1)$$

$$y = \rho_0 - \rho \cos \theta, \quad (2)$$

where

$$\rho = \frac{\sqrt{C - 2n \sin \phi}}{n} \quad (3)$$

$$\theta = n(\lambda - \lambda_0) \quad (4)$$

$$\rho_0 = \frac{\sqrt{C - 2n \sin \phi_0}}{n} \quad (5)$$

$$C = \cos^2 \phi_1 + 2n \sin \phi_1 \quad (6)$$

$$n = \frac{1}{2}(\sin \phi_1 + \sin \phi_2). \quad (7)$$

The inverse FORMULAS are

$$\phi = \sin^{-1} \left( \frac{C - \rho^2 n^2}{2n} \right) \quad (8)$$

$$\lambda = \lambda_0 + \frac{\theta}{n}, \quad (9)$$

where

$$\rho = \sqrt{x^2 + (\rho_0 - y)^2} \quad (10)$$

$$\theta = \tan^{-1} \left( \frac{x}{\rho_0 - y} \right). \quad (11)$$

**Aleph**

The SET THEORY symbol ( $\aleph$ ) for the CARDINALITY of an INFINITE SET.

see also ALEPH-0 ( $\aleph_0$ ), ALEPH-1 ( $\aleph_1$ ), COUNTABLE SET, COUNTABLY INFINITE SET, FINITE, INFINITE, TRANSFINITE NUMBER, UNCOUNTABLY INFINITE SET

**Aleph-0 ( $\aleph_0$ )**

The SET THEORY symbol for a SET having the same CARDINAL NUMBER as the "small" INFINITE SET of INTEGERS. The ALGEBRAIC NUMBERS also belong to  $\aleph_0$ . Rather surprising properties satisfied by  $\aleph_0$  include

$$\aleph_0^r = \aleph_0 \quad (1)$$

$$r\aleph_0 = \aleph_0 \quad (2)$$

$$\aleph_0 + f = \aleph_0, \quad (3)$$

where  $f$  is any FINITE SET. However,

$$\aleph_0^{\aleph_0} = C, \quad (4)$$

where  $C$  is the CONTINUUM.

see also ALEPH-1, CARDINAL NUMBER, CONTINUUM, CONTINUUM HYPOTHESIS, COUNTABLY INFINITE SET, FINITE, INFINITE, TRANSFINITE NUMBER, UNCOUNTABLY INFINITE SET

**Aleph-1 ( $\aleph_1$ )**

The SET THEORY symbol for the smallest INFINITE SET larger than ALPHA-0 ( $\aleph_0$ ). The CONTINUUM HYPOTHESIS asserts that  $\aleph_1 = c$ , where  $c$  is the CARDINALITY of the "large" INFINITE SET of REAL NUMBERS (called the CONTINUUM in SET THEORY). However, the truth of the CONTINUUM HYPOTHESIS depends on the version of SET THEORY you are using and so is UNDECIDABLE.

Curiously enough,  $n$ -D SPACE has the same number of points ( $c$ ) as 1-D SPACE, or any FINITE INTERVAL of 1-D SPACE (a LINE SEGMENT), as was first recognized by Georg Cantor.

see also ALEPH-0 ( $\aleph_0$ ), CONTINUUM, CONTINUUM HYPOTHESIS, COUNTABLY INFINITE SET, FINITE, INFINITE, TRANSFINITE NUMBER, UNCOUNTABLY INFINITE SET

**Alethic**

A term in LOGIC meaning pertaining to TRUTH and FALSEHOOD.

**Alexander-Conway Polynomial**

see CONWAY POLYNOMIAL

## Alexander's Horned Sphere

The above solid, composed of a countable UNION of COMPACT SETS, is called Alexander's horned sphere. It is HOMEOMORPHIC with the BALL  $\mathbb{B}^3$ , and its boundary is therefore a SPHERE. It is therefore an example of a wild embedding in  $\mathbb{E}^3$ . The outer complement of the solid is not SIMPLY CONNECTED, and its fundamental GROUP is not finitely generated. Furthermore, the set of nonlocally flat ("bad") points of Alexander's horned sphere is a CANTOR SET.

The complement in  $\mathbb{R}^3$  of the bad points for Alexander's horned sphere is SIMPLY CONNECTED, making it inequivalent to ANTOINE'S HORNED SPHERE. Alexander's horned sphere has an uncountable infinity of WILD POINTS, which are the limits of the sequences of the horned sphere's branch points (roughly, the "ends" of the horns), since any NEIGHBORHOOD of a limit contains a horned complex.

A humorous drawing by Simon Frazer (Guy 1983, Schroeder 1991, Albers 1994) depicts mathematician John H. Conway with Alexander's horned sphere growing from his head.

see also ANTOINE'S HORNED SPHERE

## Alexander Ideal

The order IDEAL in  $\Lambda$ , the RING of integral LAURENT POLYNOMIALS, associated with an ALEXANDER MATRIX for a KNOT  $K$ . Any generator of a principal Alexander ideal is called an ALEXANDER POLYNOMIAL. Because the ALEXANDER INVARIANT of a TAME KNOT in  $\mathbb{S}^3$  has a SQUARE presentation MATRIX, its Alexander ideal is PRINCIPAL and it has an ALEXANDER POLYNOMIAL  $\Delta(t)$ .

see also ALEXANDER INVARIANT, ALEXANDER MATRIX, ALEXANDER POLYNOMIAL

## References

- Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, pp. 206–207, 1976.

## Alexander Invariant

The Alexander invariant  $H_*(\tilde{X})$  of a KNOT  $K$  is the HOMOLOGY of the INFINITE cyclic cover of the complement of  $K$ , considered as a MODULE over  $\Lambda$ , the RING of integral LAURENT POLYNOMIALS. The Alexander invariant for a classical TAME KNOT is finitely presentable, and only  $H_1$  is significant.

For any KNOT  $K^n$  in  $\mathbb{S}^{n+2}$  whose complement has the homotopy type of a FINITE COMPLEX, the Alexander invariant is finitely generated and therefore finitely presentable. Because the Alexander invariant of a TAME KNOT in  $\mathbb{S}^3$  has a SQUARE presentation MATRIX, its ALEXANDER IDEAL is PRINCIPAL and it has an ALEXANDER POLYNOMIAL denoted  $\Delta(t)$ .

see also ALEXANDER IDEAL, ALEXANDER MATRIX, ALEXANDER POLYNOMIAL

## References

- Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, pp. 206–207, 1976.

## Alexander Matrix

A presentation matrix for the ALEXANDER INVARIANT  $H_1(\tilde{X})$  of a KNOT  $K$ . If  $V$  is a SEIFERT MATRIX for a TAME KNOT  $K$  in  $\mathbb{S}^3$ , then  $V^T - tV$  and  $V - tV^T$  are Alexander matrices for  $K$ , where  $V^T$  denotes the MATRIX TRANSPOSE.

see also ALEXANDER IDEAL, ALEXANDER INVARIANT, ALEXANDER POLYNOMIAL, SEIFERT MATRIX

## References

- Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, pp. 206–207, 1976.

**Alexander Polynomial**

A POLYNOMIAL invariant of a KNOT discovered in 1923 by J. W. Alexander (Alexander 1928). In technical language, the Alexander polynomial arises from the HOMOMORPHISM of the infinitely cyclic cover of a KNOT's complement. Any generator of a PRINCIPAL ALEXANDER IDEAL is called an Alexander polynomial (Rolfsen 1976). Because the ALEXANDER INVARIANT of a TAME KNOT in  $\mathbb{S}^3$  has a SQUARE presentation MATRIX, its ALEXANDER IDEAL is PRINCIPAL and it has an Alexander polynomial denoted  $\Delta(t)$ .

Let  $\Psi$  be the MATRIX PRODUCT of BRAID WORDS of a KNOT, then

$$\frac{\det(I - \Psi)}{1 + t + \dots + t^{n-1}} = \Delta_L, \quad (1)$$

where  $\Delta_L$  is the Alexander polynomial and  $\det$  is the DETERMINANT. The Alexander polynomial of a TAME KNOT in  $\mathbb{S}^3$  satisfies

$$\Delta(t) = \det(V^T - tV), \quad (2)$$

where  $V$  is a SEIFERT MATRIX,  $\det$  is the DETERMINANT, and  $V^T$  denotes the MATRIX TRANSPOSE. The Alexander polynomial also satisfies

$$\Delta(1) = \pm 1. \quad (3)$$

The Alexander polynomial of a splittable link is always 0. Surprisingly, there are known examples of nontrivial KNOTS with Alexander polynomial 1. An example is the  $(-3, 5, 7)$  PRETZEL KNOT.

The Alexander polynomial remained the *only* known KNOT POLYNOMIAL until the JONES POLYNOMIAL was discovered in 1984. Unlike the Alexander polynomial, the more powerful JONES POLYNOMIAL *does*, in most cases, distinguish HANDEDNESS. A normalized form of the Alexander polynomial symmetric in  $t$  and  $t^{-1}$  and satisfying

$$\Delta(\text{unknot}) = 1 \quad (4)$$

was formulated by J. H. Conway and is sometimes denoted  $\nabla_L$ . The NOTATION  $[a + b + c + \dots]$  is an abbreviation for the Conway-normalized Alexander polynomial of a KNOT

$$a + b(x + x^{-1}) + c(x^2 + x^{-2}) + \dots \quad (5)$$

For a description of the NOTATION for LINKS, see Rolfsen (1976, p. 389). Examples of the Conway-Alexander polynomials for common KNOTS include

$$\nabla_{\text{TK}} = [1 - 1 = -x^{-1} + 1 - x] \quad (6)$$

$$\nabla_{\text{FEK}} = [3 - 1 = -x^{-1} + 3 - x] \quad (7)$$

$$\nabla_{\text{SSK}} = [1 - 1 + 1 = x^{-2} - x^{-1} + 1 - x + x^2] \quad (8)$$

for the TREFOIL KNOT, FIGURE-OF-EIGHT KNOT, and SOLOMON'S SEAL KNOT, respectively. Multiplying through to clear the NEGATIVE POWERS gives the usual Alexander polynomial, where the final SIGN is determined by convention.

Let an Alexander polynomial be denoted  $\Delta$ , then there exists a SKEIN RELATIONSHIP (discovered by J. H. Conway)

$$\Delta_{L_+}(t) - \Delta_{L_-}(t) + (t^{-1/2} - t^{1/2})\Delta_{L_0}(t) = 0 \quad (9)$$

corresponding to the above LINK DIAGRAMS (Adams 1994). A slightly different SKEIN RELATIONSHIP convention used by Doll and Hoste (1991) is

$$\nabla_{L_+} - \nabla_{L_-} = z\nabla_{L_0}. \quad (10)$$

These relations allow Alexander polynomials to be constructed for arbitrary knots by building them up as a sequence of over- and undercrossings.

For a KNOT,

$$\Delta_K(-1) \equiv \begin{cases} 1 \pmod{8} & \text{if } \text{Arf}(K) = 0, \\ 5 \pmod{8} & \text{if } \text{Arf}(K) = 1, \end{cases} \quad (11)$$

where  $\text{Arf}$  is the ARF INVARIANT (Jones 1985). If  $K$  is a KNOT and

$$|\Delta_K(i)| > 3, \quad (12)$$

then  $K$  cannot be represented as a closed 3-BRAID. Also, if

$$\Delta_K(e^{2\pi i/5}) > \frac{13}{2}, \quad (13)$$

then  $K$  cannot be represented as a closed 4-braid (Jones 1985).

The HOMFLY POLYNOMIAL  $P(a, z)$  generalizes the Alexander polynomial (as well as the JONES POLYNOMIAL) with

$$\nabla(z) = P(1, z) \quad (14)$$

(Doll and Hoste 1991).

Rolfsen (1976) gives a tabulation of Alexander polynomials for KNOTS up to 10 CROSSINGS and LINKS up to 9 CROSSINGS.

## Alexander-Spanier Cohomology

A fundamental result of DE RHAM COHOMOLOGY is that the  $k$ th DE RHAM COHOMOLOGY VECTOR SPACE of a MANIFOLD  $M$  is canonically isomorphic to the Alexander-Spanier cohomology VECTOR SPACE  $H^k(M; \mathbb{R})$  (also called cohomology with compact support). In the case that  $M$  is COMPACT, Alexander-Spanier cohomology is exactly "singular" COHOMOLOGY.

## Alexander's Theorem

Any LINK can be represented by a closed BRAID.

## Algebra

The branch of mathematics dealing with GROUP THEORY and CODING THEORY which studies number systems and operations within them. The word "algebra" is a distortion of the Arabic title of a treatise by Al-Khwarizmi about algebraic methods. Note that mathematicians refer to the "school algebra" generally taught in middle and high school as "ARITHMETIC," reserving the word "algebra" for the more advanced aspects of the subject.

Formally, an algebra is a VECTOR SPACE  $V$ , over a FIELD  $F$  with a MULTIPLICATION which turns it into a RING defined such that, if  $f \in F$  and  $x, y \in V$ , then

$$f(xy) = (fx)y = x(fy).$$

In addition to the usual algebra of REAL NUMBERS, there are  $\approx 1151$  additional CONSISTENT algebras which can be formulated by weakening the FIELD AXIOMS, at least 200 of which have been *rigorously* proven to be self-CONSISTENT (Bell 1945).

Algebras which have been investigated and found to be of interest are usually named after one or more of their investigators. This practice leads to exotic-sounding (but unenlightening) names which algebraists frequently use with minimal or nonexistent explanation.

## Algebraic Closure

The algebraic closure of a FIELD  $K$  is the “smallest” FIELD containing  $K$  which is algebraically closed. For example, the FIELD of COMPLEX NUMBERS  $\mathbb{C}$  is the algebraic closure of the FIELD of REALS  $\mathbb{R}$ .

## Algebraic Coding Theory

see CODING THEORY

## Algebraic Curve

An algebraic curve over a FIELD  $K$  is an equation  $f(X, Y) = 0$ , where  $f(X, Y)$  is a POLYNOMIAL in  $X$  and  $Y$  with COEFFICIENTS in  $K$ . A nonsingular algebraic curve is an algebraic curve over  $K$  which has no SINGULAR POINTS over  $K$ . A point on an algebraic curve is simply a solution of the equation of the curve. A  $K$ -RATIONAL POINT is a point  $(X, Y)$  on the curve, where  $X$  and  $Y$  are in the FIELD  $K$ .

see also ALGEBRAIC GEOMETRY, ALGEBRAIC VARIETY, CURVE

## References

## Algebraic Integer

If  $r$  is a ROOT of the POLYNOMIAL equation

$$x^n + a_{n-1}x^{n-1} + \dots + a_1x + a_0 = 0,$$

where the  $a_i$ s are INTEGERS and  $r$  satisfies no similar equation of degree  $< n$ , then  $r$  is an algebraic INTEGER of degree  $n$ . An algebraic INTEGER is a special case of an ALGEBRAIC NUMBER, for which the leading COEFFICIENT  $a_n$  need not equal 1. RADICAL INTEGERS are a subring of the ALGEBRAIC INTEGERS.

A SUM or PRODUCT of algebraic integers is again an algebraic integer. However, ABEL'S IMPOSSIBILITY THEOREM shows that there are algebraic integers of degree  $\geq 5$  which are not expressible in terms of ADDITION, SUBTRACTION, MULTIPLICATION, DIVISION, and the extraction of ROOTS on REAL NUMBERS.

The GAUSSIAN INTEGER are algebraic integers of  $\mathbb{Q}(\sqrt{-1})$ , since  $a + bi$  are roots of

$$z^2 - 2az + a^2 + b^2 = 0.$$

## Algebraic Number

If  $r$  is a ROOT of the POLYNOMIAL equation

$$a_0x^n + a_1x^{n-1} + \dots + a_{n-1}x + a_n = 0, \quad (1)$$

where the  $a_i$ s are INTEGERS and  $r$  satisfies no similar equation of degree  $< n$ , then  $r$  is an algebraic number of degree  $n$ . If  $r$  is an algebraic number and  $a_0 = 1$ , then it is called an ALGEBRAIC INTEGER. It is also true that if the  $c_i$ s in

$$c_0x^n + c_1x^{n-1} + \dots + c_{n-1}x + c_n = 0 \quad (2)$$

are algebraic numbers, then any ROOT of this equation is also an algebraic number.

If  $\alpha$  is an algebraic number of degree  $n$  satisfying the POLYNOMIAL

$$a(x - \alpha)(x - \beta)(x - \gamma) \dots, \quad (3)$$

then there are  $n - 1$  other algebraic numbers  $\beta, \gamma, \dots$  called the conjugates of  $\alpha$ . Furthermore, if  $\alpha$  satisfies any other algebraic equation, then its conjugates also satisfy the same equation (Conway and Guy 1996).

Any number which is not algebraic is said to be TRANSCENDENTAL.

## Algebraic Number Field

see NUMBER FIELD

## Algebraic Surface

The set of ROOTS of a POLYNOMIAL  $f(x, y, z) = 0$ . An algebraic surface is said to be of degree  $n = \max(i + j + k)$ , where  $n$  is the maximum sum of powers of all terms  $a_m x^i y^j z^k$ . The following table lists the names of algebraic surfaces of a given degree.

Order	Surface
3	cubic surface
4	quartic surface
5	quintic surface
6	sextic surface
7	heptic surface
8	octic surface
9	nonic surface
10	decic surface

### Algebraic Topology

The study of intrinsic qualitative aspects of spatial objects (e.g., SURFACES, SPHERES, TORI, CIRCLES, KNOTS, LINKS, configuration spaces, etc.) that remain invariant under both-directions continuous ONE-TO-ONE (HOMEOMORPHIC) transformations. The discipline of algebraic topology is popularly known as "RUBBER-SHEET GEOMETRY" and can also be viewed as the study of DISCONNECTIVITIES. Algebraic topology has a great deal of mathematical machinery for studying different kinds of HOLE structures, and it gets the prefix "algebraic" since many HOLE structures are represented best by algebraic objects like GROUPS and RINGS.

A technical way of saying this is that algebraic topology is concerned with FUNCTORS from the topological CATEGORY of GROUPS and HOMOMORPHISMS. Here, the FUNCTORS are a kind of filter, and given an "input" SPACE, they spit out something else in return. The returned object (usually a GROUP or RING) is then a representation of the HOLE structure of the SPACE, in the sense that this algebraic object is a vestige of what the original SPACE was like (i.e., much information is lost, but some sort of "shadow" of the SPACE is retained—just enough of a shadow to understand some aspect of its HOLE-structure, but no more). The idea is that FUNCTORS give much simpler objects to deal with. Because SPACES by themselves are very complicated, they are unmanageable without looking at particular aspects.

COMBINATORIAL TOPOLOGY is a special type of algebraic topology that uses COMBINATORIAL methods.

### Algebraic Variety

A generalization to  $n$ -D of ALGEBRAIC CURVES. More technically, an algebraic variety is a reduced SCHEME of FINITE type over a FIELD  $K$ . An algebraic variety  $V$  is defined as the SET of points in the REALS  $\mathbb{R}^n$  (or the COMPLEX NUMBERS  $\mathbb{C}^n$ ) satisfying a system of POLYNOMIAL equations  $f_i(x_1, \dots, x_n) = 0$  for  $i = 1, 2, \dots$ . According to the HILBERT BASIS THEOREM, a FINITE number of equations suffices.

### Algebroidal Function

An ANALYTIC FUNCTION  $f(z)$  satisfying the irreducible algebraic equation

$$A_0(z)f^k + A_1(z)f^{k-1} + \dots + A_k(z) = 0$$

with single-valued MEROMORPHIC functions  $A_j(z)$  in a COMPLEX DOMAIN  $G$  is called a  $k$ -algebroidal function in  $G$ .

### Algorithm

A specific set of instructions for carrying out a procedure or solving a problem, usually with the requirement that the procedure terminate at some point. Specific algorithms sometimes also go by the name METHOD, PROCEDURE, or TECHNIQUE. The word "algorithm" is a distortion of Al-Khwarizmi, an Arab mathematician who wrote an influential treatise about algebraic methods.

## Alhazen's Billiard Problem

In a given CIRCLE, find an ISOSCELES TRIANGLE whose LEGS pass through two given POINTS inside the CIRCLE. This can be restated as: from two POINTS in the PLANE of a CIRCLE, draw LINES meeting at the POINT of the CIRCUMFERENCE and making equal ANGLES with the NORMAL at that POINT.

The problem is called the billiard problem because it corresponds to finding the POINT on the edge of a circular "BILLIARD" table at which a cue ball at a given POINT must be aimed in order to carom once off the edge of the table and strike another ball at a second given POINT. The solution leads to a BIQUADRATIC EQUATION of the form

$$H(x^2 - y^2) - 2Kxy + (x^2 + y^2)(hy - kx) = 0.$$

The problem is equivalent to the determination of the point on a spherical mirror where a ray of light will reflect in order to pass from a given source to an observer. It is also equivalent to the problem of finding, given two points and a CIRCLE such that the points are both inside or outside the CIRCLE, the ELLIPSE whose FOCI are the two points and which is tangent to the given CIRCLE.

The problem was first formulated by Ptolemy in 150 AD, and was named after the Arab scholar Alhazen, who discussed it in his work on optics. It was not until 1997 that Neumann proved the problem to be insoluble using a COMPASS and RULER construction because the solution requires extraction of a CUBE ROOT. This is the same reason that the CUBE DUPLICATION problem is insoluble.

## Alhazen's Problem

see ALHAZEN'S BILLIARD PROBLEM

## Alias' Paradox

Choose between the following two alternatives:

1. 90% chance of an unknown amount  $x$  and a 10% chance of \$1 million, or
2. 89% chance of the same unknown amount  $x$ , 10% chance of \$2.5 million, and 1% chance of nothing.

The PARADOX is to determine which choice has the larger expectation value,  $0.9x + \$100,000$  or  $0.89x + \$250,000$ . However, the best choice depends on the unknown amount, even though it is the same in both cases! This appears to violate the INDEPENDENCE AXIOM.

see also INDEPENDENCE AXIOM, MONTY HALL PROBLEM, NEWCOMB'S PARADOX

## Aliasing

Given a power spectrum (a plot of power vs. frequency), aliasing is a false translation of power falling in some frequency range  $(-f_c, f_c)$  outside the range. Aliasing can be caused by discrete sampling below the NYQUIST FREQUENCY. The sidelobes of any INSTRUMENT FUNCTION (including the simple SINC SQUARED function obtained simply from FINITE sampling) are also a form of aliasing. Although sidelobe contribution at large offsets can be minimized with the use of an APODIZATION FUNCTION, the tradeoff is a widening of the response (i.e., a lowering of the resolution).

see also APODIZATION FUNCTION, NYQUIST FREQUENCY

## Aliquant Divisor

A number which does not DIVIDE another exactly. For instance, 4 and 5 are aliquant divisors of 6. A number which is not an aliquant divisor (i.e., one that *does* DIVIDE another exactly) is said to be an ALIQUOT DIVISOR.

see also ALIQUOT DIVISOR, DIVISOR, PROPER DIVISOR

**Aliquot Cycle**

see SOCIABLE NUMBERS

**Aliquot Divisor**

A number which DIVIDES another exactly. For instance, 1, 2, 3, and 6 are aliquot divisors of 6. A number which is not an aliquot divisor is said to be an ALIQUANT DIVISOR. The term “aliquot” is frequently used to specifically mean a PROPER DIVISOR, i.e., a DIVISOR of a number other than the number itself.

see also ALIQUANT DIVISOR, DIVISOR, PROPER DIVISOR

**Aliquot Sequence**

Let

$$s(n) \equiv \sigma(n) - n,$$

where  $\sigma(n)$  is the DIVISOR FUNCTION and  $s(n)$  is the RESTRICTED DIVISOR FUNCTION. Then the SEQUENCE of numbers

$$s^0(n) \equiv n, s^1(n) = s(n), s^2(n) = s(s(n)), \dots$$

is called an aliquot sequence. If the SEQUENCE for a given  $n$  is bounded, it either ends at  $s(1) = 0$  or becomes periodic.

1. If the SEQUENCE reaches a constant, the constant is known as a PERFECT NUMBER.
2. If the SEQUENCE reaches an alternating pair, it is called an AMICABLE PAIR.
3. If, after  $k$  iterations, the SEQUENCE yields a cycle of minimum length  $t$  of the form  $s^{k+1}(n), s^{k+2}(n), \dots, s^{k+t}(n)$ , then these numbers form a group of SOCIABLE NUMBERS of order  $t$ .

It has not been proven that all aliquot sequences eventually terminate and become period. The smallest number whose fate is not known is 276, which has been computed up to  $s^{487}(276)$  (Guy 1994).

**All-Poles Model**

see MAXIMUM ENTROPY METHOD

**Alladi-Grinstead Constant**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let  $N(n)$  be the number of ways in which the FACTORIAL  $n!$  can be decomposed into  $n$  FACTORS of the form  $p_k^{b_k}$  arranged in nondecreasing order. Also define

$$m(n) \equiv \max(p_1^{b_1}), \quad (1)$$

i.e.,  $m(n)$  is the LEAST PRIME FACTOR raised to its appropriate POWER in the factorization. Then define

$$\alpha(n) \equiv \frac{\ln m(n)}{\ln n} \quad (2)$$

where  $\ln(x)$  is the NATURAL LOGARITHM. For instance,

$$\begin{aligned} 9! &= 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 3^4 \\ &= 2 \cdot 2 \cdot 2 \cdot 2 \cdot 3 \cdot 5 \cdot 7 \cdot 2^3 \cdot 3^3 \\ &= 2 \cdot 2 \cdot 2 \cdot 2 \cdot 5 \cdot 7 \cdot 2^3 \cdot 3^2 \cdot 3^2 \\ &= 2 \cdot 2 \cdot 2 \cdot 3 \cdot 2^2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 3^3 \\ &= 2 \cdot 2 \cdot 2 \cdot 2^2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 3^2 \cdot 3^2 \\ &= 2 \cdot 2 \cdot 2 \cdot 3 \cdot 3 \cdot 5 \cdot 7 \cdot 3^2 \cdot 2^4 \\ &= 2 \cdot 2 \cdot 3 \cdot 3 \cdot 2^2 \cdot 5 \cdot 7 \cdot 2^3 \cdot 3^2 \\ &= 2 \cdot 2 \cdot 3 \cdot 3 \cdot 3 \cdot 3 \cdot 5 \cdot 7 \cdot 2^5 \\ &= 2 \cdot 3 \cdot 3 \cdot 2^2 \cdot 2^2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 3^2 \\ &= 2 \cdot 3 \cdot 3 \cdot 3 \cdot 3 \cdot 2^2 \cdot 5 \cdot 7 \cdot 2^4 \\ &= 2 \cdot 3 \cdot 3 \cdot 3 \cdot 3 \cdot 5 \cdot 7 \cdot 2^3 \cdot 2^3 \\ &= 3 \cdot 3 \cdot 3 \cdot 3 \cdot 2^2 \cdot 2^2 \cdot 5 \cdot 7 \cdot 2^3, \end{aligned} \quad (3)$$

so

$$\alpha(9) = \frac{\ln 3}{\ln 9} = \frac{\ln 3}{2 \ln 3} = \frac{1}{2}. \quad (4)$$

For large  $n$ ,

$$\lim_{n \rightarrow \infty} \alpha(n) = e^{c-1} = 0.809394020534 \dots, \quad (5)$$

where

$$c \equiv \sum_{k=2}^{\infty} \frac{1}{k} \ln \left( \frac{k}{k-1} \right). \quad (6)$$

**Almost All**

Given a property  $P$ , if  $P(x) \sim x$  as  $x \rightarrow \infty$  (so the number of numbers less than  $x$  not satisfying the property  $P$  is  $o(x)$ ), then  $P$  is said to hold true for almost all numbers. For example, almost all positive integers are COMPOSITE NUMBERS (which is not in conflict with the second of EUCLID'S THEOREMS that there are an infinite number of PRIMES).

see also FOR ALL, NORMAL ORDER

References

**Almost Alternating Knot**

An ALMOST ALTERNATING LINK with a single component.

**Almost Alternating Link**

Call a projection of a LINK an almost alternating projection if one crossing change in the projection makes it an alternating projection. Then an almost alternating link is a LINK with an almost alternating projection, but no alternating projection. Every ALTERNATING KNOT has an almost alternating projection. A PRIME KNOT which is almost alternating is either a TORUS KNOT or a HYPERBOLIC KNOT. Therefore, no SATELLITE KNOT is an almost alternating knot.

All nonalternating 9-crossing PRIME KNOTS are almost alternating. Of the 393 nonalternating with 11 or fewer crossings, all but five are known to be nonalternating (3 of these have 11 crossings). The fate of the remaining five is not known. The (2,  $q$ ), (3, 4), and (3, 5)-TORUS KNOTS are almost alternating.

**Almost Everywhere**

A property of  $X$  is said to hold almost everywhere if the SET of points in  $X$  where this property fails has MEASURE 0.

see also MEASURE

References

Sansone, G. *Orthogonal Functions*, rev. English ed. New York: Dover, p. 1, 1991.

**Almost Integer**

A number which is very close to an INTEGER. One surprising example involving both  $e$  and  $\pi$  is

$$e^\pi - \pi = 19.999099979 \dots, \quad (1)$$

which can also be written as

$$(\pi + 20)^i = -0.9999999992 - 0.0000388927i \approx -1 \quad (2)$$

$$\cos(\ln(\pi + 20)) \approx -0.9999999992. \quad (3)$$

Applying COSINE a few more times gives

$$\begin{aligned} \cos(\pi \cos(\pi \cos(\ln(\pi + 20)))) \\ \approx -1 + 3.9321609261 \times 10^{-35}. \end{aligned} \quad (4)$$

This curious near-identity was apparently noticed almost simultaneously around 1988 by N. J. A. Sloane, J. H. Conway, and S. Plouffe, but no satisfying explanation as to “why” it has been true has yet been discovered.

An interesting near-identity is given by

$$\begin{aligned} \frac{1}{4} \left[ \cos\left(\frac{1}{10}\right) + \cosh\left(\frac{1}{10}\right) + 2 \cos\left(\frac{1}{20}\sqrt{2}\right) \cosh\left(\frac{1}{20}\sqrt{2}\right) \right] \\ = 1 + 2.480 \dots \times 10^{-13} \end{aligned} \quad (5)$$

(W. Dubuque). Other remarkable near-identities are given by

$$\frac{5(1 + \sqrt{5})[\Gamma(\frac{3}{4})]^2}{e^{5\pi/6}\sqrt{\pi}} = 1 + 4.5422 \dots \times 10^{-14}, \quad (6)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION (S. Plouffe), and

$$e^6 - \pi^4 - \pi^5 = 0.000017673 \dots \quad (7)$$

(D. Wilson).

A whole class of IRRATIONAL “almost integers” can be found using the theory of MODULAR FUNCTIONS, and a few rather spectacular examples are given by Ramanujan (1913–14). Such approximations were also studied by Hermite (1859), Kronecker (1863), and Smith (1965). They can be generated using some amazing (and very deep) properties of the  $j$ -FUNCTION. Some of the numbers which are closest approximations to INTEGERS are  $e^{\pi\sqrt{163}}$  (sometimes known as the RAMANUJAN CONSTANT and which corresponds to the field  $\mathbb{Q}(\sqrt{-163})$  which has CLASS NUMBER 1 and is the IMAGINARY quadratic field of maximal discriminant),  $e^{\pi\sqrt{22}}$ ,  $e^{\pi\sqrt{37}}$ , and  $e^{\pi\sqrt{58}}$ , the latter three of which have CLASS NUMBER 2 and are due to Ramanujan (Berndt 1994, Waldschmidt 1988).

The properties of the  $j$ -FUNCTION also give rise to the spectacular identity

$$\left[ \frac{\ln(640320^3 + 744)}{\pi} \right]^2 = 163 + 2.32167 \dots \times 10^{-29} \quad (8)$$

(Le Lionnais 1983, p. 152).

The list below gives numbers of the form  $x \equiv e^{\pi\sqrt{n}}$  for  $n \leq 1000$  for which  $[x] - x \leq 0.01$ .

$$\begin{aligned} e^{\pi\sqrt{6}} &= 2, 197.990\,869\,543 \dots \\ e^{\pi\sqrt{17}} &= 422, 150.997\,675\,680 \dots \\ e^{\pi\sqrt{18}} &= 614, 551.992\,885\,619 \dots \\ e^{\pi\sqrt{22}} &= 2, 508, 951.998\,257\,553 \dots \\ e^{\pi\sqrt{25}} &= 6, 635, 623.999\,341\,134 \dots \\ e^{\pi\sqrt{37}} &= 199, 148, 647.999\,978\,046\,551 \dots \\ e^{\pi\sqrt{43}} &= 884, 736, 743.999\,777\,466 \dots \\ e^{\pi\sqrt{58}} &= 24, 591, 257, 751.999\,999\,822\,213 \dots \\ e^{\pi\sqrt{59}} &= 30, 197, 683, 486.993\,182\,260 \dots \\ e^{\pi\sqrt{67}} &= 147, 197, 952, 743.999\,998\,662\,454 \dots \\ e^{\pi\sqrt{74}} &= 54, 551, 812, 208.999\,917\,467\,885 \dots \\ e^{\pi\sqrt{149}} &= 45, 116, 546, 012, 289, 599.991\,830\,287 \dots \\ e^{\pi\sqrt{163}} &= 262, 537, 412, 640, 768, 743.999\,999\,999\,999\,250\,072 \dots \\ e^{\pi\sqrt{177}} &= 1, 418, 556, 986, 635, 586, 485.996\,179\,355 \dots \\ e^{\pi\sqrt{232}} &= 604, 729, 957, 825, 300, 084, 759.999\,992\,171\,526 \dots \\ e^{\pi\sqrt{267}} &= 19, 683, 091, 854, 079, 461, 001, 445.992\,737\,040 \dots \\ \\ e^{\pi\sqrt{326}} &= 4, 309, 793, 301, 730, 386, 363, 005, 719.996\,011\,651 \dots \\ e^{\pi\sqrt{386}} &= 639, 355, 180, 631, 208, 421, \dots \\ &\quad \dots 212, 174, 016.997\,669\,832 \dots \\ e^{\pi\sqrt{522}} &= 14, 871, 070, 263, 238, 043, 663, 567, \dots \\ &\quad \dots 627, 879, 007.999\,848\,726 \dots \\ e^{\pi\sqrt{566}} &= 288, 099, 755, 064, 053, 264, 917, 867, \dots \\ &\quad \dots 975, 825, 573.993\,898\,311 \dots \\ e^{\pi\sqrt{638}} &= 28, 994, 858, 898, 043, 231, 996, 779, \dots \\ &\quad \dots 771, 804, 797, 161.992\,372\,939 \dots \\ e^{\pi\sqrt{719}} &= 3, 842, 614, 373, 539, 548, 891, 490, \dots \\ &\quad \dots 294, 277, 805, 829, 192.999\,987\,249 \dots \\ e^{\pi\sqrt{790}} &= 223, 070, 667, 213, 077, 889, 794, 379, \dots \\ &\quad \dots 623, 183, 838, 336, 437.992\,055\,118 \dots \\ e^{\pi\sqrt{792}} &= 249, 433, 117, 287, 892, 229, 255, 125, \dots \\ &\quad \dots 388, 685, 911, 710, 805.996\,097\,323 \dots \\ e^{\pi\sqrt{926}} &= 365, 698, 321, 891, 389, 219, 219, 142, \dots \\ &\quad \dots 531, 076, 638, 716, 362, 775.998\,259\,747 \dots \\ e^{\pi\sqrt{986}} &= 6, 954, 830, 200, 814, 801, 770, 418, 837, \dots \\ &\quad \quad \quad 940, 281, 460, 320, 666, 108.994\,649\,611 \dots \end{aligned}$$

Gosper noted that the expression

$$1 - 262537412640768744e^{-\pi\sqrt{163}} - 196884e^{-2\pi\sqrt{163}} + 103378831900730205293632e^{-3\pi\sqrt{163}}. \quad (9)$$

differs from an INTEGER by a mere  $10^{-59}$ .

#### Almost Perfect Number

A number  $n$  for which the DIVISOR FUNCTION satisfies  $\sigma(n) = 2n - 1$  is called almost perfect. The only known almost perfect numbers are the POWERS of 2, namely 1, 2, 4, 8, 16, 32, ... (Sloane's A000079). Singh (1997) calls almost perfect numbers SLIGHTLY DEFECTIVE.

see also QUASIPERFECT NUMBER

#### Almost Prime

A number  $n$  with prime factorization

$$n = \prod_{i=1}^r p_i^{a_i}$$

is called  $k$ -almost prime when the sum of the POWERS  $\sum_{i=1}^r a_i = k$ . The set of  $k$ -almost primes is denoted  $P_k$ .

The PRIMES correspond to the “1-almost prime” numbers 2, 3, 5, 7, 11, ... (Sloane's A000040). The 2-almost prime numbers correspond to SEMIPRIMES 4, 6, 9, 10, 14, 15, 21, 22, ... (Sloane's A001358). The first few 3-almost primes are 8, 12, 18, 20, 27, 28, 30, 42, 44, 45, 50, 52, 63, 66, 68, 70, 75, 76, 78, 92, 98, 99, ... (Sloane's A014612). The first few 4-almost primes are 16, 24, 36, 40, 54, 56, 60, 81, 84, 88, 90, 100, ... (Sloane's A014613). The first few 5-almost primes are 32, 48, 72, 80, ... (Sloane's A014614).

### Alpha

A financial measure giving the difference between a fund's actual return and its expected level of performance, given its level of risk (as measured by BETA). A POSITIVE alpha indicates that a fund has performed better than expected based on its BETA, whereas a NEGATIVE alpha indicates poorer performance

see also BETA, SHARPE RATIO

### Alpha Function

$$\alpha_n(z) \equiv \int_1^{\infty} t^n e^{-zt} dt = n! z^{-(n+1)} e^{-z} \sum_{k=0}^n \frac{z^k}{k!}.$$

The alpha function satisfies the RECURRENCE RELATION

$$z\alpha_n(z) = e^{-z} + n\alpha_{n-1}(z).$$

see also BETA FUNCTION (EXPONENTIAL)

### Alpha Value

An alpha value is a number  $0 \leq \alpha \leq 1$  such that  $P(z \geq z_{\text{observed}}) \leq \alpha$  is considered "SIGNIFICANT," where  $P$  is a  $P$ -VALUE.

see also CONFIDENCE INTERVAL,  $P$ -VALUE, SIGNIFICANCE

### Alphabet

A SET (usually of letters) from which a SUBSET is drawn. A sequence of letters is called a WORD, and a set of WORDS is called a CODE.

see also CODE, WORD

### Alphamagic Square

A MAGIC SQUARE for which the number of letters in the word for each number generates another MAGIC SQUARE. This definition depends, of course, on the language being used. In English, for example,

5	22	18	4	9	8
28	15	2	11	7	3
12	8	25	6	5	10

where the MAGIC SQUARE on the right corresponds to the number of letters in

five	twenty-two	eighteen
twenty-eight	fifteen	two
twelve	eight	twenty-five

### Alternate Algebra

Let  $A$  denote an  $\mathbb{R}$ -ALGEBRA, so that  $A$  is a VECTOR SPACE over  $\mathbb{R}$  and

$$A \times A \rightarrow A \quad (1)$$

$$(x, y) \mapsto x \cdot y. \quad (2)$$

Then  $A$  is said to be alternate if, for all  $x, y \in A$ ,

$$(x \cdot y) \cdot y = x \cdot (y \cdot y) \quad (3)$$

$$(x \cdot x) \cdot y = x \cdot (x \cdot y). \quad (4)$$

Here, VECTOR MULTIPLICATION  $x \cdot y$  is assumed to be BILINEAR.

see EXTERIOR ALGEBRA

**Alternating Group**

EVEN PERMUTATION GROUPS  $A_n$  which are NORMAL SUBGROUPS of the PERMUTATION GROUP of ORDER  $n!/2$ . They are FINITE analogs of the families of simple LIE GROUPS. The lowest order alternating group is 60. Alternating groups with  $n \geq 5$  are non-ABELIAN SIMPLE GROUPS. The number of conjugacy classes in the alternating groups  $A_n$  for  $n = 2, 3, \dots$  are 1, 3, 4, 5, 7, 9,  $\dots$  (Sloane's A000702).

**Alternating Knot**

An alternating knot is a KNOT which possesses a knot diagram in which crossings alternate between under- and overpasses. Not all knot diagrams of alternating knots need be alternating diagrams.

The TREFOIL KNOT and FIGURE-OF-EIGHT KNOT are alternating knots. One of TAIT'S KNOT CONJECTURES states that the number of crossings is the same for any diagram of a reduced alternating knot. Furthermore, a reduced alternating projection of a knot has the least number of crossings for any projection of that knot. Both of these facts were proved true by Kauffman (1988), Thistlethwaite (1987), and Murasugi (1987).

If  $K$  has a reduced alternating projection of  $n$  crossings, then the SPAN of  $K$  is  $4n$ . Let  $c(K)$  be the CROSSING NUMBER. Then an alternating knot  $K_1 \# K_2$  (a KNOT SUM) satisfies

$$c(K_1 \# K_2) = c(K_1) + c(K_2).$$

In fact, this is true as well for the larger class of ADEQUATE KNOTS and postulated for all KNOTS. The number of PRIME alternating knots of  $n$  crossing for  $n = 1, 2, \dots$  are 0, 0, 1, 1, 2, 3, 7, 18, 41, 123, 367,  $\dots$  (Sloane's A002864).

**Alternating Permutation**

An arrangement of the elements  $c_1, \dots, c_n$  such that no element  $c_i$  has a magnitude between  $c_{i-1}$  and  $c_{i+1}$  is called an alternating (or ZIGZAG) permutation. The determination of the number of alternating permutations for the set of the first  $n$  INTEGERS  $\{1, 2, \dots, n\}$  is known as ANDRÉ'S PROBLEM. An example of an alternating permutation is (1, 3, 2, 5, 4).

As many alternating permutations among  $n$  elements begin by rising as by falling. The magnitude of the  $c_n$ s does not matter; only the number of them. Let the number of alternating permutations be given by  $Z_n = 2A_n$ . This quantity can then be computed from

$$2na_n = \sum a_r a_s, \quad (1)$$

where  $r$  and  $s$  pass through all INTEGRAL numbers such that

$$r + s = n - 1, \quad (2)$$

$a_0 = a_1 = 1$ , and

$$A_n = n!a_n. \quad (3)$$

The numbers  $A_n$  are sometimes called the EULER ZIGZAG NUMBERS, and the first few are given by 1, 1, 1, 2, 5, 16, 61, 272,  $\dots$  (Sloane's A000111). The ODD-numbered  $A_n$ s are called EULER NUMBERS, SECANT NUMBERS, or ZIG NUMBERS, and the EVEN-numbered ones are sometimes called TANGENT NUMBERS or ZAG NUMBERS.

Curiously enough, the SECANT and TANGENT MACLAURIN SERIES can be written in terms of the  $A_n$ s as

$$\sec x = A_0 + A_2 \frac{x^2}{2!} + A_4 \frac{x^4}{4!} + \dots \quad (4)$$

$$\tan x = A_1 x + A_3 \frac{x^3}{3!} + A_5 \frac{x^5}{5!} + \dots, \quad (5)$$

or combining them,

$$\sec x + \tan x = A_0 + A_1 x + A_2 \frac{x^2}{2!} + A_3 \frac{x^3}{3!} + A_4 \frac{x^4}{4!} + A_5 \frac{x^5}{5!} + \dots \quad (6)$$

#### Altitude

The altitudes of a TRIANGLE are the CEVIANS  $A_i H_i$  which are PERPENDICULAR to the LEGS  $A_j A_k$  opposite  $A_i$ . They have lengths  $h_i \equiv \overline{A_i H_i}$  given by

$$h_i = a_{i+1} \sin \alpha_{i+2} = a_{i+2} \sin \alpha_{i+1} \quad (1)$$

$$h_1 = \frac{2\sqrt{s(s-a_1)(s-a_2)(s-a_3)}}{a_1}, \quad (2)$$

where  $s$  is the SEMIPERIMETER and  $a_i \equiv \overline{A_j A_k}$ . Another interesting FORMULA is

$$h_1 h_2 h_3 = 2s\Delta \quad (3)$$

(Johnson 1929, p. 191), where  $\Delta$  is the AREA of the TRIANGLE. The three altitudes of any TRIANGLE are CONCURRENT at the ORTHOCENTER  $H$ . This fundamental fact did not appear anywhere in Euclid's *Elements*.

Other formulas satisfied by the altitude include

$$\frac{1}{h_1} + \frac{1}{h_2} + \frac{1}{h_3} = \frac{1}{r} \quad (4)$$

$$\frac{1}{r_1} = \frac{1}{h_2} + \frac{1}{h_3} - \frac{1}{h_1} \quad (5)$$

$$\frac{1}{r_2} + \frac{1}{r_3} = \frac{1}{r} - \frac{1}{r_1} = \frac{2}{h_1}, \quad (6)$$

where  $r$  is the INRADIUS and  $r_i$  are the EXRADII (Johnson 1929, p. 189). In addition,

$$HA_1 \cdot HH_1 = HA_2 \cdot HH_2 = HA_3 \cdot HH_3 \quad (7)$$

$$HA_1 \cdot HH_1 = \frac{1}{2}(a_1^2 + a_2^2 + a_3^2) - 4R^2, \quad (8)$$

where  $R$  is the CIRCUMRADIUS.

The points  $A_1, A_3, H_1$ , and  $H_3$  (and their permutations with respect to indices) all lie on a CIRCLE, as do the points  $A_3, H_3, H$ , and  $H_1$  (and their permutations with respect to indices). TRIANGLES  $\Delta A_1 A_2 A_3$  and  $\Delta A_1 H_2 H_3$  are inversely similar.

The triangle  $H_1 H_2 H_3$  has the minimum PERIMETER of any TRIANGLE inscribed in a given ACUTE TRIANGLE (Johnson 1929, pp. 161–165). The PERIMETER of  $\Delta H_1 H_2 H_3$  is  $2\Delta/R$  (Johnson 1929, p. 191). Additional properties involving the FEET of the altitudes are given by Johnson (1929, pp. 261–262).

#### Alysoid

see CATENARY

#### Ambient Isotopy

An ambient isotopy from an embedding of a MANIFOLD  $M$  in  $N$  to another is a HOMOTOPY of self DIFFEOMORPHISMS (or ISOMORPHISMS, or piecewise-linear transformations, etc.) of  $N$ , starting at the IDENTITY MAP, such that the “last” DIFFEOMORPHISM compounded with the first embedding of  $M$  is the second embedding of  $M$ . In other words, an ambient isotopy is like an ISOTOPY except that instead of distorting the embedding, the whole ambient SPACE is being stretched and distorted and the embedding is just “coming along for the ride.”

For SMOOTH MANIFOLDS, a MAP is ISOTOPIC IFF it is ambiently isotopic.

For KNOTS, the equivalence of MANIFOLDS under continuous deformation is independent of the embedding SPACE. KNOTS of opposite CHIRALITY have ambient isotopy, but not REGULAR ISOTOPY.

see also ISOTOPY, REGULAR ISOTOPY

#### References

- Hirsch, M. W. *Differential Topology*. New York: Springer-Verlag, 1988.

#### Ambiguous

An expression is said to be ambiguous (or poorly defined) if its definition does not assign it a unique interpretation or value. An expression which is *not* ambiguous is said to be WELL-DEFINED.

see also WELL-DEFINED

#### Ambrose-Kakutani Theorem

For every ergodic FLOW on a nonatomic PROBABILITY SPACE, there is a MEASURABLE SET intersecting almost every orbit in a discrete set.

#### Amenable Number

A number  $n$  which can be built up from INTEGERS  $a_1, a_2, \dots, a_k$  by either ADDITION or MULTIPLICATION such that

$$\sum_{i=1}^k a_i = \prod_{i=1}^k a_i = n.$$

The numbers  $\{a_1, \dots, a_n\}$  in the SUM are simply a PARTITION of  $n$ . The first few amenable numbers are

$$2 + 2 = 2 \times 2 = 4$$

$$1 + 2 + 3 = 1 \times 2 \times 3 = 6$$

$$1 + 1 + 2 + 4 = 1 \times 1 \times 2 \times 4 = 8$$

$$1 + 1 + 2 + 2 + 2 = 1 \times 1 \times 2 \times 2 \times 2 = 8.$$

In fact, all COMPOSITE NUMBERS are amenable.

#### Amicable Numbers

see AMICABLE PAIR, AMICABLE QUADRUPLE, AMICABLE TRIPLE, MULTIAMICABLE NUMBERS

**Amicable Pair**

An amicable pair consists of two INTEGERS  $m, n$  for which the sum of PROPER DIVISORS (the DIVISORS excluding the number itself) of one number equals the other. Amicable pairs are occasionally called FRIENDLY PAIRS, although this nomenclature is to be discouraged since FRIENDLY PAIRS are defined by a different, if related, criterion. Symbolically, amicable pairs satisfy

$$s(m) = n \quad (1)$$

$$s(n) = m, \quad (2)$$

where  $s(n)$  is the RESTRICTED DIVISOR FUNCTION or, equivalently,

$$\sigma(m) = \sigma(n) = s(m) + s(n) = m + n, \quad (3)$$

where  $\sigma(n)$  is the DIVISOR FUNCTION. The smallest amicable pair is (220, 284) which has factorizations

$$220 = 11 \cdot 5 \cdot 2^2 \quad (4)$$

$$284 = 71 \cdot 2^2 \quad (5)$$

giving RESTRICTED DIVISOR FUNCTIONS

$$\begin{aligned} s(220) &= \sum \{1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110\} \\ &= 284 \end{aligned} \quad (6)$$

$$\begin{aligned} s(284) &= \sum \{1, 2, 4, 71, 142\} \\ &= 220. \end{aligned} \quad (7)$$

The quantity

$$\sigma(m) = \sigma(n) = s(m) + s(n), \quad (8)$$

in this case,  $220 + 284 = 504$ , is called the PAIR SUM.

In 1636, Fermat found the pair (17296, 18416) and in 1638, Descartes found (9363584, 9437056). By 1747, Euler had found 30 pairs, a number which he later extended to 60. There were 390 known as of 1946 (Scott 1946). There are a total of 236 amicable pairs below  $10^8$  (Cohen 1970), 1427 below  $10^{10}$  (te Riele 1986), 3340 less than  $10^{11}$  (Moews and Moews 1993), and less than  $2.01 \times 10^{11}$  (Moews and Moews), and 5001 less than  $\approx 3.06 \times 10^{11}$  (Moews and Moews).

The first few amicable pairs are (220, 284), (1184, 1210), (2620, 2924) (5020, 5564), (6232, 6368), (10744, 10856), (12285, 14595), (17296, 18416), (63020, 76084), ... (Sloane's A002025 and A002046). An exhaustive tabulation is maintained by D. Moews.

Let an amicable pair be denoted  $(m, n)$  with  $m < n$ .  $(m, n)$  is called a regular amicable pair of type  $(i, j)$  if

$$(m, n) = (gM, gN), \quad (9)$$

where  $g \equiv \text{GCD}(m, n)$  is the GREATEST COMMON DIVISOR,

$$\text{GCD}(g, M) = \text{GCD}(g, N) = 1, \quad (10)$$

$M$  and  $N$  are SQUAREFREE, then the number of PRIME factors of  $M$  and  $N$  are  $i$  and  $j$ . Pairs which are not regular are called irregular or exotic (te Riele 1986). There are no regular pairs of type  $(1, j)$  for  $j \geq 1$ . If  $m \equiv 0 \pmod{6}$  and

$$n = \sigma(m) - m \quad (11)$$

is EVEN, then  $(m, n)$  cannot be an amicable pair (Lee 1969). The minimal and maximal values of  $m/n$  found by te Riele (1986) were

$$938304290/1344480478 = 0.697893577 \dots \quad (12)$$

and

$$4000783984/4001351168 = 0.9998582519 \dots \quad (13)$$

te Riele (1986) also found 37 pairs of amicable pairs having the same PAIR SUM. The first such pair is (609928, 686072) and (643336, 652664), which has the PAIR SUM

$$\sigma(m) = \sigma(n) = m + n = 1,296,000. \quad (14)$$

te Riele (1986) found no amicable  $n$ -tuples having the same PAIR SUM for  $n > 2$ . However, Moews and Moews found a triple in 1993, and te Riele found a quadruple in 1995. In November 1997, a quintuple and sextuple were discovered. The sextuple is (1953433861918, 2216492794082), (1968039941816, 2201886714184), (1981957651366, 2187969004634), (1993501042130, 2176425613870), (2046897812505, 2123028843495), (2068113162038, 2101813493962), all having PAIR SUM 4169926656000. Amazingly, the sextuple is smaller than any known quadruple or quintuple, and is likely smaller than any quintuple.

On October 4, 1997, Mariano Garcia found the largest known amicable pair, each of whose members has 4829 DIGITS. The new pair is

$$N_1 = CM[(P + Q)P^{89} - 1] \quad (15)$$

$$N_2 = CQ[(P - M)P^{89} - 1], \quad (16)$$

where

$$C = 2^{11}P^{89} \quad (17)$$

$$M = 287155430510003638403359267 \quad (18)$$

$$P = 574451143340278962374313859 \quad (19)$$

$$Q = 136272576607912041393307632916794623. \quad (20)$$

$P, Q, (P + Q)P^{89} - 1$ , and  $(P - M)P^{89} - 1$  are PRIME.

Pomerance (1981) has proved that

$$[\text{amicable numbers} \leq n] < ne^{-[\ln(n)]^{1/3}} \quad (21)$$

for large enough  $n$  (Guy 1994). No nonfinite lower bound has been proven.

## Amicable Quadruple

An amicable quadruple as a QUADRUPLE  $(a, b, c, d)$  such that

$$\sigma(a) = \sigma(b) = \sigma(c) = \sigma(d) = a + b + c + d,$$

where  $\sigma(n)$  is the DIVISOR FUNCTION.

## References

- Guy, R. K. *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, p. 59, 1994.

## Amicable Triple

Dickson (1913, 1952) defined an amicable triple to be a TRIPLE of three numbers  $(l, m, n)$  such that

$$s(l) = m + n$$

$$s(m) = l + n$$

$$s(n) = l + m,$$

where  $s(n)$  is the RESTRICTED DIVISOR FUNCTION (Madachy 1979). Dickson (1913, 1952) found eight sets of amicable triples with two equal numbers, and two sets with distinct numbers. The latter are (123228768, 103340640, 124015008), for which

$$s(12322876) = 103340640 + 124015008 = 227355648$$

$$s(103340640) = 123228768 + 124015008 = 24724377$$

$$s(124015008) = 123228768 + 103340640 = 226569408,$$

and (1945330728960, 2324196638720, 2615631953920), for which

$$\begin{aligned}s(1945330728960) &= 2324196638720 + 2615631953920 \\ &= 4939828592640 \\ s(2324196638720) &= 1945330728960 + 2615631953920 \\ &= 4560962682880 \\ s(2615631953920) &= 1945330728960 + 2324196638720 \\ &= 4269527367680.\end{aligned}$$

A second definition (Guy 1994) defines an amicable triple as a TRIPLE  $(a, b, c)$  such that

$$\sigma(a) = \sigma(b) = \sigma(c) = a + b + c,$$

where  $\sigma(n)$  is the DIVISOR FUNCTION. An example is  $(2^2 3^2 5 \cdot 11, 2^5 3^2 7, 2^2 3^2 71)$ .

#### Amortization

The payment of a debt plus accrued INTEREST by regular payments.

#### Ampersand Curve

The PLANE CURVE with Cartesian equation

$$(y^2 - x^2)(x - 1)(2x - 3) = 4(x^2 + y^2 - 2x)^2.$$

#### References

- Cundy, H. and Rollett, A. *Mathematical Models, 3rd ed.* Stradbroke, England: Tarquin Pub., p. 72, 1989.

#### Amphichiral

An object is amphichiral (also called REFLEXIBLE) if it is superposable with its MIRROR IMAGE (i.e., its image in a plane mirror).

see also AMPHICHIRAL KNOT, CHIRAL, DISYMMETRIC, HANDEDNESS, MIRROR IMAGE

#### Amphichiral Knot

An amphichiral knot is a KNOT which is capable of being continuously deformed into its own MIRROR IMAGE. The amphichiral knots having ten or fewer crossings are  $04_{001}$  (FIGURE-OF-EIGHT KNOT),  $06_{003}$ ,  $08_{003}$ ,  $08_{009}$ ,  $08_{012}$ ,  $08_{017}$ ,  $08_{018}$ ,  $10_{017}, 10_{033}$ ,  $10_{037}$ ,  $10_{043}$ ,  $10_{045}$ ,  $10_{079}$ ,  $10_{081}$ ,  $10_{088}$ ,  $10_{099}$ ,  $10_{109}$ ,  $10_{115}$ ,  $10_{118}$ , and  $10_{123}$  (Jones 1985). The HOMFLY POLYNOMIAL is good at identifying amphichiral knots, but sometimes fails to identify knots which are not. No complete invariant (an invariant which always definitively determines if a KNOT is AMPHICHIRAL) is known.

Let  $b_+$  be the SUM of POSITIVE exponents, and  $b_-$  the SUM of NEGATIVE exponents in the BRAID GROUP  $B_n$ . If

$$b_+ - 3b_- - n + 1 > 0,$$

then the KNOT corresponding to the closed BRAID  $b$  is not amphichiral (Jones 1985).

#### Amplitude

The variable  $\phi$  used in ELLIPTIC FUNCTIONS and ELLIPTIC INTEGRALS, which can be defined by

$$\phi = \text{am } u \equiv \int \text{dn } u \, du,$$

where  $\text{dn}(u)$  is a JACOBI ELLIPTIC FUNCTION. The term "amplitude" is also used to refer to the maximum offset of a function from its baseline level.

**Anallagmatic Curve**

A curve which is invariant under INVERSION. Examples include the CARDIOID, CARTESIAN OVALS, CASSINI OVALS, LIMAÇON, STROPHOID, and MACLAURIN TRISECTRIX.

**Anallagmatic Pavement**

see HADAMARD MATRIX

**Analogy**

Inference of the TRUTH of an unknown result obtained by noting its similarity to a result already known to be TRUE. In the hands of a skilled mathematician, analogy can be a very powerful tool for suggesting new and extending old results. However, subtleties can render results obtained by analogy incorrect, so rigorous PROOF is still needed.

see also INDUCTION

**Analysis**

The study of how continuous mathematical structures (FUNCTIONS) vary around the NEIGHBORHOOD of a point on a SURFACE. Analysis includes CALCULUS, DIFFERENTIAL EQUATIONS, etc.

see also ANALYSIS SITUS, CALCULUS, COMPLEX ANALYSIS, FUNCTIONAL ANALYSIS, NONSTANDARD ANALYSIS, REAL ANALYSIS

**Analytic Function**

A FUNCTION in the COMPLEX NUMBERS  $\mathbb{C}$  is analytic on a region  $R$  if it is COMPLEX DIFFERENTIABLE at every point in  $R$ . The terms HOLOMORPHIC FUNCTION and REGULAR FUNCTION are sometimes used interchangeably with “analytic function.” If a FUNCTION is analytic, it is infinitely DIFFERENTIABLE.

**Analytic Set**

A DEFINABLE SET, also called a SOUSLIN SET.

see also COANALYTIC SET, SOUSLIN SET

**Anarboricity**

Given a GRAPH  $G$ , the anarboricity is the maximum number of line-disjoint nonacyclic SUBGRAPHS whose UNION is  $G$ .

see also ARBORICITY

**Anchor**

An anchor is the BUNDLE MAP  $\rho$  from a VECTOR BUNDLE  $A$  to the TANGENT BUNDLE  $TB$  satisfying

1.  $[\rho(X), \rho(Y)] = \rho([X, Y])$  and
2.  $[X, \phi Y] = \phi[X, Y] + (\rho(X) \cdot \phi)Y$ ,

where  $X$  and  $Y$  are smooth sections of  $A$ ,  $\phi$  is a smooth function of  $B$ , and the bracket is the “Jacobi-Lie bracket” of a VECTOR FIELD.

**And**

A term (PREDICATE) in LOGIC which yields TRUE if one or more conditions are TRUE, and FALSE if any condition is FALSE.  $A$  AND  $B$  is denoted  $A \& B$ ,  $A \wedge B$ , or simply  $AB$ . The BINARY AND operator has the following TRUTH TABLE:

$A$	$B$	$A \wedge B$
F	F	F
F	T	F
T	F	F
T	T	T

A PRODUCT of ANDs (the AND of  $n$  conditions) is called a CONJUNCTION, and is denoted

$$\bigwedge_{k=1}^n A_k.$$

Two binary numbers can have the operation AND performed bitwise with 1 representing TRUE and 0 FALSE. Some computer languages denote this operation on  $A$ ,  $B$ , and  $C$  as  $A \& B \& C$  or  $\text{logand}(A, B, C)$ .

see also BINARY OPERATOR, INTERSECTION, NOT, OR, PREDICATE, TRUTH TABLE, XOR

**Anderson-Darling Statistic**

A statistic defined to improve the KOLMOGOROV-SMIRNOV TEST in the TAIL of a distribution.

see also KOLMOGOROV-SMIRNOV TEST, KUIPER STATISTIC

**Andrews Cube**

see SEMIPERFECT MAGIC CUBE

**Andrews-Curtis Link**

The LINK of 2-spheres in  $\mathbb{R}^4$  obtained by SPINNING intertwined arcs. The link consists of a knotted 2-sphere and a SPUN TREFOIL KNOT.

see also SPUN KNOT, TREFOIL KNOT

References

- Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, p. 94, 1976.

**Andrews-Schur Identity**

$$\begin{aligned} & \sum_{k=0}^n q^{k^2+ak} \begin{bmatrix} 2n-k+a \\ k \end{bmatrix} \\ &= \sum_{k=-\infty}^{\infty} q^{10k^2+(4a-1)k} \begin{bmatrix} 2n+2a+2 \\ n-5k \end{bmatrix} \frac{[10k+2a+2]}{[2n+2a+2]}, \end{aligned} \quad (1)$$

where  $[x]$  is a GAUSSIAN POLYNOMIAL. It is a POLYNOMIAL identity for  $a = 0, 1$  which implies the ROGERS-RAMANUJAN IDENTITIES by taking  $n \rightarrow \infty$  and applying the JACOBI TRIPLE PRODUCT identity. A variant of this equation is

$$\begin{aligned} \sum_{k=-[a/2]}^n q^{k^2+2ak} \begin{bmatrix} n+k+a \\ n-k \end{bmatrix} \\ = \sum_{k=-[(n+2a+2)/5]}^{[n/5]} q^{15k^2+(6a+1)k} \begin{bmatrix} 2n+2a+2 \\ 5-5k \end{bmatrix} \\ \times \frac{[10k+2a+2]}{[2n+2a+2]}, \quad (2) \end{aligned}$$

where the symbol  $[x]$  in the SUM limits is the FLOOR FUNCTION (Paule 1994). The RECIPROCAL of the identity is

$$\begin{aligned} \sum_{k=0}^{\infty} \frac{q^{k^2+2ak}}{(q; q)_{2k+a}} \\ = \prod_{j=0}^{\infty} \frac{1}{(1-q^{2j+1})(1-q^{20j+4a+4})(1-q^{20j-4a+16})} \quad (3) \end{aligned}$$

for  $a = 0, 1$  (Paule 1994). For  $q = 1$ , (1) and (2) become

$$\begin{aligned} \sum_{k=-[a/2]}^n \binom{n+k+a}{n-k} \\ = \sum_{k=-[(n+2a+2)/5]}^{[n/5]} \binom{2n+2a+2}{n-5k} \frac{5k+a+1}{n+a+1}. \quad (4) \end{aligned}$$

### Andrica's Conjecture

Andrica's conjecture states that, for  $p_n$  the  $n$ th PRIME NUMBER, the INEQUALITY

$$A_n \equiv \sqrt{p_{n+1}} - \sqrt{p_n} < 1$$

holds, where the discrete function  $A_n$  is plotted above. The largest value among the first 1000 PRIMES is for  $n = 4$ , giving  $\sqrt{11} - \sqrt{7} \approx 0.670873$ . Since the Andrica function falls asymptotically as  $n$  increases so a PRIME GAP of increasing size is needed at large  $n$ , it seems likely the CONJECTURE is true. However, it has not yet been proven.

$A_n$  bears a strong resemblance to the PRIME DIFFERENCE FUNCTION, plotted above, the first few values of which are 1, 2, 2, 4, 2, 4, 2, 4, 6, 2, 6, ... (Sloane's A001223).

### Anger Function

A generalization of the BESSEL FUNCTION OF THE FIRST KIND defined by

$$\mathcal{J}_\nu(z) \equiv \frac{1}{\pi} \int_0^\pi \cos(\nu\theta - z \sin \theta) d\theta.$$

If  $\nu$  is an INTEGER  $n$ , then  $\mathcal{J}_n(z) = J_n(z)$ , where  $J_n(z)$  is a BESSEL FUNCTION OF THE FIRST KIND. Anger's original function had an upper limit of  $2\pi$ , but the current NOTATION was standardized by Watson (1966).

## Angle

Given two intersecting LINES or LINE SEGMENTS, the amount of ROTATION about the point of intersection (the VERTEX) required to bring one into correspondence with the other is called the angle  $\theta$  between them. Angles are usually measured in DEGREES (denoted  $^\circ$ ), RADIANs (denoted rad, or without a unit), or sometimes GRADIANS (denoted grad).

One full rotation in these three measures corresponds to  $360^\circ$ ,  $2\pi$  rad, or 400 grad. Half a full ROTATION is called a STRAIGHT ANGLE, and a QUARTER of a full rotation is called a RIGHT ANGLE. An angle less than a RIGHT ANGLE is called an ACUTE ANGLE, and an angle greater than a RIGHT ANGLE is called an OBTUSE ANGLE.

The use of DEGREES to measure angles harks back to the Babylonians, whose SEXAGESIMAL number system was based on the number 60.  $360^\circ$  likely arises from the Babylonian year, which was composed of 360 days (12 months of 30 days each). The DEGREE is further divided into 60 ARC MINUTES, and an ARC MINUTE into 60 ARC SECONDS. A more natural measure of an angle is the RADIAN. It has the property that the ARC LENGTH around a CIRCLE is simply given by the radian angle measure times the CIRCLE RADIUS. The RADIAN is also the most useful angle measure in CALCULUS because the DERIVATIVE of TRIGONOMETRIC functions such as

$$\frac{d}{dx} \sin x = \cos x$$

does not require the insertion of multiplicative constants like  $\pi/180$ . GRADIANS are sometimes used in surveying (they have the nice property that a RIGHT ANGLE is exactly 100 GRADIANS), but are encountered infrequently, if at all, in mathematics.

The concept of an angle can be generalized from the CIRCLE to the SPHERE. The fraction of a SPHERE subtended by an object is measured in STERADIANS, with the entire SPHERE corresponding to  $4\pi$  STERADIANS.

A ruled SEMICIRCLE used for measuring and drawing angles is called a PROTRACTOR. A COMPASS can also be used to draw circular ARCS of some angular extent.

## Angle Bisector

The (interior) bisector of an ANGLE is the LINE or LINE SEGMENT which cuts it into two equal ANGLES on the same "side" as the ANGLE.

The length of the bisector of ANGLE  $A_1$  in the above TRIANGLE  $\Delta A_1 A_2 A_3$  is given by

$$t_1^2 = a_2 a_3 \left[ 1 - \frac{a_1^2}{(a_2 + a_3)^2} \right],$$

where  $t_i \equiv \overline{A_i T_i}$  and  $a_i \equiv \overline{A_j A_k}$ . The angle bisectors meet at the INCENTER  $I$ , which has TRILINEAR COORDINATES 1:1:1.

see also ANGLE BISECTOR THEOREM, CYCLIC QUADRANGLE, EXTERIOR ANGLE BISECTOR, ISODYNAMIC POINTS, ORTHOCENTRIC SYSTEM, STEINER-LEHMUS THEOREM, TRISECTION

## Angle Bisector Theorem

The ANGLE BISECTOR of an ANGLE in a TRIANGLE divides the opposite side in the same RATIO as the sides adjacent to the ANGLE.

## Angle Bracket

The combination of a BRA and KET (bra+ket = bracket) which represents the INNER PRODUCT of two functions or vectors,

$$\langle f|g \rangle = \int f(x)g(x) dx$$

$$\langle \mathbf{v}|\mathbf{w} \rangle = \mathbf{v} \cdot \mathbf{w}.$$

By itself, the BRA is a COVARIANT 1-VECTOR, and the KET is a COVARIANT ONE-FORM. These terms are commonly used in quantum mechanics.

see also BRA, DIFFERENTIAL  $k$ -FORM, KET, ONE-FORM

**Angle of Parallelism**

Given a point  $P$  and a LINE  $AB$ , draw the PERPENDICULAR through  $P$  and call it  $PC$ . Let  $PD$  be any other line from  $P$  which meets  $CB$  in  $D$ . In a HYPERBOLIC GEOMETRY, as  $D$  moves off to infinity along  $CB$ , then the line  $PD$  approaches the limiting line  $PE$ , which is said to be parallel to  $CB$  at  $P$ . The angle  $\angle CPE$  which  $PE$  makes with  $PC$  is then called the angle of parallelism for perpendicular distance  $x$ , and is given by

$$\Pi(x) = 2 \tan^{-1}(e^{-x}).$$

This is known as LOBACHEVSKY'S FORMULA.

see also HYPERBOLIC GEOMETRY, LOBACHEVSKY'S FORMULA

**Angle Trisection**

see TRISECTION

**Angular Acceleration**

The angular acceleration  $\alpha$  is defined as the time DERIVATIVE of the ANGULAR VELOCITY  $\omega$ ,

$$\alpha \equiv \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2} \hat{\mathbf{z}} = \frac{\mathbf{a}}{r}.$$

see also ACCELERATION, ANGULAR DISTANCE, ANGULAR VELOCITY

**Angular Defect**

The DIFFERENCE between the SUM of face ANGLES  $A_i$  at a VERTEX of a POLYHEDRON and  $2\pi$ ,

$$\delta = 2\pi - \sum_i A_i.$$

see also DESCARTES TOTAL ANGULAR DEFECT, JUMP ANGLE

**Angular Distance**

The angular distance traveled around a CIRCLE is the number of RADIANS the path subtends,

$$\theta \equiv \frac{\ell}{2\pi r} 2\pi = \frac{\ell}{r}.$$

see also ANGULAR ACCELERATION, ANGULAR VELOCITY

**Angular Velocity**

The angular velocity  $\omega$  is the time DERIVATIVE of the ANGULAR DISTANCE  $\theta$  with direction  $\hat{\mathbf{z}}$  PERPENDICULAR to the plane of angular motion,

$$\omega \equiv \frac{d\theta}{dt} \hat{\mathbf{z}} = \frac{\mathbf{v}}{r}.$$

see also ANGULAR ACCELERATION, ANGULAR DISTANCE

**Anharmonic Ratio**

see CROSS-RATIO

**Anisohedral Tiling**

A  $k$ -anisohedral tiling is a tiling which permits no  $n$ -ISOHEDRAL TILING with  $n < k$ .

**References**

**Annihilator**

The term annihilator is used in several different ways in various aspects of mathematics. It is most commonly used to mean the SET of all functions satisfying a given set of conditions which is zero on every member of a given SET.

**Annulus**

The region in common to two concentric CIRCLES of RADII  $a$  and  $b$ . The AREA of an annulus is

$$A_{\text{annulus}} = \pi(b^2 - a^2).$$

An interesting identity is as follows. In the figure,

the AREA of the shaded region  $A$  is given by

$$A = C_1 + C_2.$$

 Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, p. 38, 1976.

**Anomalous Cancellation**

The simplification of a FRACTION  $a/b$  which gives a correct answer by "canceling" DIGITS of  $a$  and  $b$ . There are only four such cases for NUMERATOR and DENOMINATORS of two DIGITS in base 10:  $64/16 = 4/1 = 4$ ,  $98/49 = 8/4 = 2$ ,  $95/19 = 5/1 = 5$ , and  $65/26 = 5/2$  (Boas 1979).

The concept of anomalous cancellation can be extended to arbitrary bases. PRIME bases have no solutions, but there is a solution corresponding to each PROPER DIVISOR of a COMPOSITE  $b$ . When  $b - 1$  is PRIME, this type of solution is the only one. For base 4, for example, the only solution is  $32_4/13_4 = 2_4$ . Boas gives a table of solutions for  $b \leq 39$ . The number of solutions is EVEN unless  $b$  is an EVEN SQUARE.

$b$	$N$	$b$	$N$
4	1	26	4
6	2	27	6
8	2	28	10
9	2	30	6
10	4	32	4
12	4	34	6
14	2	35	6
15	6	36	21
16	7	38	2
18	4	39	6
20	4		
21	10		
22	6		
24	6

**Anomalous Number**

see BENFORD'S LAW

**Anonymous**

A term in SOCIAL CHOICE THEORY meaning invariance of a result under permutation of voters.

see also DUAL VOTING, MONOTONIC VOTING

**Anosov Automorphism**

A HYPERBOLIC linear map  $\mathbb{R}^n \rightarrow \mathbb{R}^n$  with INTEGER entries in the transformation MATRIX and DETERMINANT  $\pm 1$  is an ANOSOV DIFFEOMORPHISM of the  $n$ -TORUS, called an Anosov automorphism (or HYPERBOLIC AUTOMORPHISM). Here, the term automorphism is used in the GROUP THEORY sense.

**Anosov Diffeomorphism**

An Anosov diffeomorphism is a  $C^1$  DIFFEOMORPHISM  $\phi$  such that the MANIFOLD  $M$  is HYPERBOLIC with respect to  $\phi$ . Very few classes of Anosov diffeomorphisms are known. The best known is ARNOLD'S CAT MAP.

A HYPERBOLIC linear map  $\mathbb{R}^n \rightarrow \mathbb{R}^n$  with INTEGER entries in the transformation MATRIX and DETERMINANT  $\pm 1$  is an Anosov diffeomorphism of the  $n$ -TORUS. Not every MANIFOLD admits an Anosov diffeomorphism. Anosov diffeomorphisms are EXPANSIVE, and there are no Anosov diffeomorphisms on the CIRCLE.

It is conjectured that if  $\phi : M \rightarrow M$  is an Anosov diffeomorphism on a COMPACT RIEMANNIAN MANIFOLD and the NONWANDERING SET  $\Omega(\phi)$  of  $\phi$  is  $M$ , then  $\phi$  is TOPOLOGICALLY CONJUGATE to a FINITE-TO-ONE FACTOR of an ANOSOV AUTOMORPHISM of a NILMANIFOLD. It has been proved that any Anosov diffeomorphism on the  $n$ -TORUS is TOPOLOGICALLY CONJUGATE to an ANOSOV AUTOMORPHISM, and also that Anosov diffeomorphisms are  $C^1$  STRUCTURALLY STABLE.

**Anosov Flow**

A FLOW defined analogously to the ANOSOV DIFFEOMORPHISM, except that instead of splitting the TANGENT BUNDLE into two invariant sub-BUNDLES, they are split into three (one exponentially contracting, one expanding, and one which is 1-dimensional and tangential to the flow direction).

see also DYNAMICAL SYSTEM

**Anosov Map**

An important example of a ANOSOV DIFFEOMORPHISM.

$$\begin{bmatrix} x_{n+1} \\ y_{n+1} \end{bmatrix} = \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix},$$

where  $x_{n+1}, y_{n+1}$  are computed mod 1.

see also ARNOLD'S CAT MAP

**ANOVA**

"Analysis of Variance." A STATISTICAL TEST for heterogeneity of MEANS by analysis of group VARIANCES. To apply the test, assume random sampling of a variate  $y$  with equal VARIANCES, independent errors, and a NORMAL DISTRIBUTION. Let  $n$  be the number of REPLICATES (sets of identical observations) within each of  $K$  FACTOR LEVELS (treatment groups), and  $y_{ij}$  be the  $j$ th observation within FACTOR LEVEL  $i$ . Also assume that the ANOVA is "balanced" by restricting  $n$  to be the same for each FACTOR LEVEL.

Now define the sum of square terms

$$SST \equiv \sum_{i=1}^k \sum_{j=1}^n (y_{ij} - \bar{y})^2 \quad (1)$$

$$= \sum_{i=1}^k \sum_{j=1}^n y_{ij}^2 - \frac{\left( \sum_{i=1}^k \sum_{j=1}^n y_{ij} \right)^2}{Kn} \quad (2)$$

$$SSA \equiv \frac{1}{n} \sum_{i=1}^k \left( \sum_{j=1}^n y_{ij} \right)^2 - \frac{1}{Kn} \left( \sum_{i=1}^k \sum_{j=1}^n y_{ij} \right)^2 \quad (3)$$

$$SSE \equiv \sum_{i=1}^k \sum_{j=1}^n (y_{ij} - \bar{y}_i)^2 \quad (4)$$

$$= SST - SSA, \quad (5)$$

which are the total, treatment, and error sums of squares. Here,  $\bar{y}_i$  is the mean of observations within FACTOR LEVEL  $i$ , and  $\bar{y}$  is the "group" mean (i.e., mean of means). Compute the entries in the following table, obtaining the  $P$ -VALUE corresponding to the calculated  $F$ -RATIO of the mean squared values

$$F = \frac{MSA}{MSE}. \quad (6)$$

Category	SS	°Freedom	Mean Squared	$F$ -Ratio
treatment	SSA	$K - 1$	$MSA \equiv \frac{SSA}{K-1}$	$\frac{MSA}{MSE}$
error	SSE	$K(n - 1)$	$MSE \equiv \frac{SSE}{K(n-1)}$	
total	SST	$Kn - 1$	$MST \equiv \frac{SST}{Kn-1}$	

If the  $P$ -VALUE is small, reject the NULL HYPOTHESIS that all MEANS are the same for the different groups.

see also FACTOR LEVEL, REPLICATE, VARIANCE

**Anthropomorphic Polygon**

A SIMPLE POLYGON with precisely two EARS and one MOUTH.

**References**

Toussaint, G. "Anthropomorphic Polygons." *Amer. Math. Monthly* **122**, 31–35, 1991.

**Anthyphairetic Ratio**

An archaic word for a CONTINUED FRACTION.

**References**

Sloane, N. J. A. Sequence A006826/M2469 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Anticlastic**

When the GAUSSIAN CURVATURE  $K$  is everywhere NEGATIVE, a SURFACE is called anticlastic and is saddle-shaped. A SURFACE on which  $K$  is everywhere POSITIVE is called SYNCLASTIC. A point at which the GAUSSIAN CURVATURE is NEGATIVE is called a HYPERBOLIC POINT.

see also ELLIPTIC POINT, GAUSSIAN QUADRATURE, HYPERBOLIC POINT, PARABOLIC POINT, PLANAR POINT, SYNCLASTIC

**Anticommutative**

An OPERATOR  $*$  for which  $a * b = -b * a$  is said to be anticommutative.

see also COMMUTATIVE

**Anticommutator**

For OPERATORS  $\tilde{A}$  and  $\tilde{B}$ , the anticommutator is defined by

$$\{\tilde{A}, \tilde{B}\} \equiv \tilde{A}\tilde{B} + \tilde{B}\tilde{A}.$$

see also COMMUTATOR, JORDAN ALGEBRA

**Anticomplementary Triangle**

A TRIANGLE  $\Delta A'B'C'$  which has a given TRIANGLE  $\Delta ABC$  as its MEDIAL TRIANGLE. The TRILINEAR COORDINATES of the anticomplementary triangle are

$$\begin{aligned} A' &= -a^{-1} : b^{-1} : c^{-1} \\ B' &= a^{-1} : -b^{-1} : c^{-1} \\ C' &= a^{-1} : b^{-1} : -c^{-1}. \end{aligned}$$

see also MEDIAL TRIANGLE

**Antiderivative**

see INTEGRAL

**Antidifferentiation**

see INTEGRATION

**Antigonal Points**

Given  $\angle AXB + \angle AYB = \pi$  RADIANS in the above figure, then  $X$  and  $Y$  are said to be antigonal points with respect to  $A$  and  $B$ .

**Antihomography**

A CIRCLE-preserving TRANSFORMATION composed of an ODD number of INVERSIONS.

see also HOMOGRAPHY

**Antihomologous Points**

Two points which are COLLINEAR with respect to a SIMILITUDE CENTER but are not HOMOLOGOUS POINTS. Four interesting theorems from Johnson (1929) follow.

1. Two pairs of antihomologous points form inversely similar triangles with the HOMOTHETIC CENTER.
2. The PRODUCT of distances from a HOMOTHETIC CENTER to two antihomologous points is a constant.
3. Any two pairs of points which are antihomologous with respect to a SIMILITUDE CENTER lie on a CIRCLE.
4. The tangents to two CIRCLES at antihomologous points make equal ANGLES with the LINE through the points.

see also HOMOLOGOUS POINTS, HOMOTHETIC CENTER, SIMILITUDE CENTER

**References**

An antimagic square is an  $n \times n$  ARRAY of integers from 1 to  $n^2$  such that each row, column, and main diagonal produces a different sum such that these sums form a SEQUENCE of consecutive integers. It is therefore a special case of a HETEROSQUARE.

Antimagic squares of orders one and two are impossible, and it is believed that there are also no antimagic squares of order three. There are 18 families of antimagic squares of order four. Antimagic squares of orders 4–9 are illustrated above (Madachy 1979).

## Antipedal Triangle

The antipedal triangle  $A$  of a given TRIANGLE  $T$  is the TRIANGLE of which  $T$  is the PEDAL TRIANGLE. For a TRIANGLE with TRILINEAR COORDINATES  $\alpha : \beta : \gamma$  and ANGLES  $A$ ,  $B$ , and  $C$ , the antipedal triangle has VERTICES with TRILINEAR COORDINATES

$$\begin{aligned} &-(\beta + \alpha \cos C)(\gamma + \alpha \cos B) : (\gamma + \alpha \cos B)(\alpha + \beta \cos C) : \\ &\quad (\beta + \alpha \cos C)(\alpha + \gamma \cos B) \\ &(\gamma + \beta \cos A)(\beta + \alpha \cos C) : -(\gamma + \beta \cos A)(\alpha + \beta \cos C) : \\ &\quad (\alpha + \beta \cos C)(\beta + \gamma \cos A) \\ &(\beta + \gamma \cos A)(\gamma + \alpha \cos B) : (\alpha + \gamma \cos B)(\gamma + \beta \cos A) : \\ &\quad -(\alpha + \gamma \cos B)(\beta + \gamma \cos A). \end{aligned}$$

The ISOGONAL CONJUGATE of the ANTIPEDAL TRIANGLE of a given TRIANGLE is HOMOTHETIC with the original TRIANGLE. Furthermore, the PRODUCT of their AREAS equals the SQUARE of the AREA of the original TRIANGLE (Gallatly 1913).

## Antipersistent Process

A FRACTAL PROCESS for which  $H < 1/2$ , so  $r < 0$ .

see also PERSISTENT PROCESS

## Antipodal Map

The MAP which takes points on the surface of a SPHERE  $S^2$  to their ANTIPODAL POINTS.

## Antipodal Points

Two points are antipodal (i.e., each is the ANTIPODE of the other) if they are diametrically opposite. Examples include endpoints of a LINE SEGMENT, or poles of a SPHERE. Given a point on a SPHERE with LATITUDE  $\delta$  and LONGITUDE  $\lambda$ , the antipodal point has LATITUDE  $-\delta$  and LONGITUDE  $\lambda \pm 180^\circ$  (where the sign is taken so that the result is between  $-180^\circ$  and  $+180^\circ$ ).

see also ANTIPODE, DIAMETER, GREAT CIRCLE, SPHERE

## Antipode

Given a point  $A$ , the point  $B$  which is the ANTIPODAL POINT of  $A$  is said to be the antipode of  $A$ .

see also ANTIPODAL POINTS

## Antiprism

A SEMIREGULAR POLYHEDRON constructed with  $2n$   $n$ -gons and  $2n$  TRIANGLES. The 3-antiprism is simply the OCTAHEDRON. The DUALS are the TRAPEZOHEDRA. The SURFACE AREA of a  $n$ -gonal antiprism is

$$\begin{aligned} S &= 2A_{n\text{-gon}} + 2nA_{\Delta} \\ &= 2 \left[ \frac{1}{4}na^2 \cot \left( \frac{\pi}{n} \right) \right] + 2n \left( \frac{1}{4}\sqrt{3}a^2 \right) \\ &= \frac{1}{2}na^2 \left[ \cot \left( \frac{\pi}{n} \right) + \sqrt{3} \right]. \end{aligned}$$

see also OCTAHEDRON, PRISM, PRISMOID, TRAPEZOHEDRON

## Antiquity

see GEOMETRIC PROBLEMS OF ANTIQUITY

## Antisnowflake

see KOCH ANTISNOWFLAKE

## Antisquare Number

A number of the form  $p^a \cdot A$  is said to be an antisquare if it fails to be a SQUARE NUMBER for the two reasons that  $a$  is ODD and  $A$  is a nonsquare modulo  $p$ .

see also SQUARE NUMBER

## Antisymmetric

A quantity which changes SIGN when indices are reversed. For example,  $A_{ij} \equiv a_i - a_j$  is antisymmetric since  $A_{ij} = -A_{ji}$ .

see also ANTISYMMETRIC MATRIX, ANTISYMMETRIC TENSOR, SYMMETRIC

## Antisymmetric Matrix

An antisymmetric matrix is a MATRIX which satisfies the identity

$$A = -A^T \quad (1)$$

where  $A^T$  is the MATRIX TRANSPOSE. In component notation, this becomes

$$a_{ij} = -a_{ji}. \quad (2)$$

Letting  $k = i = j$ , the requirement becomes

$$a_{kk} = -a_{kk}, \quad (3)$$

so an antisymmetric matrix must have zeros on its diagonal. The general  $3 \times 3$  antisymmetric matrix is of the form

$$\begin{bmatrix} 0 & a_{12} & a_{13} \\ -a_{12} & 0 & a_{23} \\ -a_{13} & -a_{23} & 0 \end{bmatrix}. \quad (4)$$

Applying  $A^{-1}$  to both sides of the antisymmetry condition gives

$$-A^{-1}A^T = I. \quad (5)$$

Any SQUARE MATRIX can be expressed as the sum of symmetric and antisymmetric parts. Write

$$A = \frac{1}{2}(A + A^T) + \frac{1}{2}(A - A^T). \quad (6)$$

Now

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \quad (7)$$

$$A^T = \begin{bmatrix} a_{11} & a_{21} & \cdots & a_{n1} \\ a_{12} & a_{22} & \cdots & a_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n} & a_{2n} & \cdots & a_{nn} \end{bmatrix}, \quad (8)$$

so

$$A + A^T = \begin{bmatrix} 2a_{11} & a_{12} + a_{21} & \cdots & a_{1n} + a_{n1} \\ a_{12} + a_{21} & 2a_{22} & \cdots & a_{2n} + a_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n} + a_{n1} & a_{2n} + a_{n2} & \cdots & 2a_{nn} \end{bmatrix}, \quad (9)$$

which is symmetric, and

$$A - A^T = \begin{bmatrix} 0 & a_{12} - a_{21} & \cdots & a_{1n} - a_{n1} \\ -(a_{12} - a_{21}) & 0 & \cdots & a_{2n} - a_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ -(a_{1n} - a_{n1}) & -(a_{2n} - a_{n2}) & \cdots & 0 \end{bmatrix}, \quad (10)$$

which is antisymmetric.

see also SKEW SYMMETRIC MATRIX, SYMMETRIC MATRIX

### Antisymmetric Relation

A RELATION  $R$  on a SET  $S$  is antisymmetric provided that distinct elements are never both related to one another. In other words  $xRy$  and  $yRx$  together imply that  $x = y$ .

### Antisymmetric Tensor

An antisymmetric tensor is defined as a TENSOR for which

$$A^{mn} = -A^{nm}. \quad (1)$$

Any TENSOR can be written as a sum of SYMMETRIC and antisymmetric parts as

$$A^{mn} = \frac{1}{2}(A^{mn} + A^{nm}) + \frac{1}{2}(A^{mn} - A^{nm}). \quad (2)$$

The antisymmetric part is sometimes denoted using the special notation

$$A^{[ab]} = \frac{1}{2}(A^{ab} - A^{ba}). \quad (3)$$

For a general TENSOR,

$$A^{[a_1 \cdots a_n]} \equiv \frac{1}{n!} \epsilon_{a_1 \cdots a_n} \sum_{\text{permutations}} A^{a_1 \cdots a_n}, \quad (4)$$

where  $\epsilon_{a_1 \cdots a_n}$  is the LEVI-CIVITA SYMBOL, a.k.a. the PERMUTATION SYMBOL.

see also SYMMETRIC TENSOR

### Antoine's Horned Sphere

A topological 2-sphere in 3-space whose exterior is not SIMPLY CONNECTED. The outer complement of Antoine's horned sphere is not SIMPLY CONNECTED. Furthermore, the group of the outer complement is not even finitely generated. Antoine's horned sphere is inequivalent to ALEXANDER'S HORNED SPHERE since the complement in  $\mathbb{R}^3$  of the bad points for ALEXANDER'S HORNED SPHERE is SIMPLY CONNECTED.

see also ALEXANDER'S HORNED SPHERE

### Antoine's Necklace

Construct a chain  $C$  of  $2n$  components in a solid TORUS  $V$ . Now form a chain  $C_1$  of  $2n$  solid tori in  $V$ , where

$$\pi_1(V - C_1) \cong \pi_1(V - C)$$

via inclusion. In each component of  $C_1$ , construct a smaller chain of solid tori embedded in that component. Denote the union of these smaller solid tori  $C_2$ . Continue this process a countable number of times, then the intersection

$$A = \bigcap_{i=1}^{\infty} C_i$$

which is a nonempty compact SUBSET of  $\mathbb{R}^3$  is called Antoine's necklace. Antoine's necklace is HOMEOMORPHIC with the CANTOR SET.

**Apéry's Constant**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Apéry's constant is defined by

$$\zeta(3) = 1.2020569 \dots, \quad (1)$$

(Sloane's A002117) where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION. Apéry (1979) proved that  $\zeta(3)$  is IRRATIONAL, although it is not known if it is TRANSCENDENTAL. The CONTINUED FRACTION for  $\zeta(3)$  is  $[1, 4, 1, 18, 1, 1, 1, 4, 1, \dots]$  (Sloane's A013631). The positions at which the numbers 1, 2, ... occur in the continued fraction are 1, 12, 25, 2, 64, 27, 17, 140, 10, ....

Sums related to  $\zeta(3)$  are

$$\zeta(3) = \frac{5}{2} \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^3 \binom{2n}{n}} = \frac{5}{2} \sum_{k=1}^{\infty} \frac{(-1)^{k+1} (k!)^2}{(2k)! k^3} \quad (2)$$

(used by Apéry), and

$$\lambda(3) = \sum_{k=0}^{\infty} \frac{1}{(2k+1)^3} = \frac{7}{8} \zeta(3) \quad (3)$$

$$\sum_{k=0}^{\infty} \frac{1}{(3k+1)^3} = \frac{2\pi^3}{81\sqrt{3}} + \frac{13}{27} \zeta(3) \quad (4)$$

$$\sum_{k=0}^{\infty} \frac{1}{(4k+1)^3} = \frac{\pi^3}{64} + \frac{7}{16} \zeta(3) \quad (5)$$

$$\sum_{k=0}^{\infty} \frac{1}{(6k+1)^3} = \frac{\pi^3}{36\sqrt{3}} + \frac{91}{216} \zeta(3), \quad (6)$$

where  $\lambda(z)$  is the DIRICHLET LAMBDA FUNCTION. The above equations are special cases of a general result due to Ramanujan (Berndt 1985). Apéry's proof relied on showing that the sum

$$a(n) \equiv \sum_{k=0}^n \binom{n}{k}^2 \binom{n+k}{k}^2, \quad (7)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT, satisfies the RECURRENCE RELATION

$$(n+1)^3 a(n+1) - (34n^3 + 51n^2 + 27n + 5) a(n) + n^3 a(n-1) = 0 \quad (8)$$

(van der Poorten 1979, Zeilberger 1991).

Apéry's constant is also given by

$$\zeta(3) = \sum_{n=1}^{\infty} \frac{S_{n,2}}{n!n}, \quad (9)$$

where  $S_{n,m}$  is a STIRLING NUMBER OF THE FIRST KIND. This can be rewritten as

$$\sum_{n=1}^{\infty} \frac{H_n}{n^2} = 2\zeta(3), \quad (10)$$

where  $H_n$  is the  $n$ th HARMONIC NUMBER. Yet another expression for  $\zeta(3)$  is

$$\zeta(3) = \frac{1}{2} \sum_{n=1}^{\infty} \frac{1}{n^2} \left(1 + \frac{1}{2} + \dots + \frac{1}{n}\right) \quad (11)$$

(Castellanos 1988).

INTEGRALS for  $\zeta(3)$  include

$$\zeta(3) = \frac{1}{2} \int_0^{\infty} \frac{t^2}{e^t - 1} dt \quad (12)$$

$$= \frac{8}{7} \left[ \frac{1}{4} \pi^2 \ln 2 + 2 \int_0^{\pi/4} x \ln(\sin x) dx \right]. \quad (13)$$

Gosper (1990) gave

$$\zeta(3) = \frac{1}{4} \sum_{k=1}^{\infty} \frac{30k - 11}{(2k-1)k^3 \binom{2k}{k}^2}. \quad (14)$$

A CONTINUED FRACTION involving Apéry's constant is

$$\frac{6}{\zeta(3)} = 5 - \frac{1^6}{117-} \frac{2^6}{535-} \dots \frac{n^6}{34n^3 + 51n^2 + 27n + 5-} \dots \quad (15)$$

(Apéry 1979, Le Lionnais 1983). Amdeberhan (1996) used WILF-ZEILBERGER PAIRS  $(F, G)$  with

$$F(n, k) = \frac{(-1)^k k!^2 (sn - k - 1)!}{(sn + k + 1)! (k + 1)!}, \quad (16)$$

$s = 1$  to obtain

$$\zeta(3) = \frac{5}{2} \sum_{n=1}^{\infty} (-1)^{n-1} \frac{1}{\binom{2n}{n} n^3}. \quad (17)$$

For  $s = 2$ ,

$$\zeta(3) = \frac{1}{4} \sum_{n=1}^{\infty} (-1)^{n-1} \frac{56n^2 - 32 + 5}{(2n-1)^2} \frac{1}{\binom{3n}{n} \binom{2n}{n} n^3} \quad (18)$$

and for  $s = 3$ ,

$$\zeta(3) = \sum_{n=0}^{\infty} \frac{(-1)^n}{72 \binom{4n}{n} \binom{3n}{n}} \times \frac{6120n + 5265n^4 + 13761n^2 + 13878n^3 + 1040}{(4n+1)(4n+3)(n+1)(3n+1)^2(3n+2)^2} \quad (19)$$

(Amdeberhan 1996). The corresponding  $G(n, k)$  for  $s = 1$  and 2 are

$$G(n, k) = \frac{2(-1)^k k!^2 (n-k)!}{(n+k+1)!(n+1)^2} \quad (20)$$

and

$$G(n, k) = \frac{(-1)^k k!^2 (2n-k)!(3+4n)(4n^2+6n+k+3)}{2(2n+k+2)!(n+1)^2(2n+1)^2}. \quad (21)$$

Gosper (1996) expressed  $\zeta(3)$  as the MATRIX PRODUCT

$$\lim_{N \rightarrow \infty} \prod_{n=1}^N M_n = \begin{bmatrix} 0 & \zeta(3) \\ 0 & 1 \end{bmatrix}, \quad (22)$$

where

$$M_n \equiv \begin{bmatrix} \frac{(n+1)^4}{4096(n+\frac{5}{4})^2(n+\frac{7}{4})^2} & \frac{24570n^4 + 64161n^3 + 62152n^2 + 26427n + 4154}{31104(n+\frac{1}{3})(n+\frac{1}{2})(n+\frac{2}{3})} \\ 0 & 1 \end{bmatrix} \quad (23)$$

which gives 12 bits per term. The first few terms are

$$M_1 = \begin{bmatrix} \frac{1}{19600} & \frac{2077}{1728} \\ 0 & 1 \end{bmatrix} \quad (24)$$

$$M_2 = \begin{bmatrix} \frac{1}{9801} & \frac{7561}{4320} \\ 0 & 1 \end{bmatrix} \quad (25)$$

$$M_3 = \begin{bmatrix} \frac{9}{67600} & \frac{50501}{20160} \\ 0 & 1 \end{bmatrix}, \quad (26)$$

which gives

$$\zeta(3) \approx \frac{423203577229}{352066176000} = 1.20205690315732 \dots \quad (27)$$

Given three INTEGERS chosen at random, the probability that no common factor will divide them all is

$$[\zeta(3)]^{-1} \approx 1.202^{-1} = 0.832 \dots \quad (28)$$

B. Haible and T. Papanikolaou computed  $\zeta(3)$  to 1,000,000 DIGITS using a WILF-ZEILBERGER PAIR identity with

$$F(n, k) = (-1)^k \frac{n!^6 (2n-k-1)! k!^3}{2(n+k+1)!^2 (2n)!^3}, \quad (29)$$

$s = 1$ , and  $t = 1$ , giving the rapidly converging

$$\zeta(3) = \sum_{n=0}^{\infty} (-1)^n \frac{n!^{10} (205n^2 + 250n + 77)}{64(2n+1)!^5} \quad (30)$$

(Amdeberhan and Zeilberger 1997). The record as of Aug. 1998 was 64 million digits (Plouffe).

## Apoapsis

The greatest radial distance of an ELLIPSE as measured from a FOCUS. Taking  $v = \pi$  in the equation of an ELLIPSE

$$r = \frac{a(1 - e^2)}{1 + e \cos v}$$

gives the apoapsis distance

$$r_+ = a(1 + e).$$

Apoapsis for an orbit around the Earth is called apogee, and apoapsis for an orbit around the Sun is called aphelion.

see also ECCENTRICITY, ELLIPSE, FOCUS, PERIAPSIS

## Apocalypse Number

A number having 666 DIGITS (where 666 is the BEAST NUMBER) is called an apocalypse number. The FIBONACCI NUMBER  $F_{3184}$  is an apocalypse number.

see also BEAST NUMBER, LEVIATHAN NUMBER

## References

Pickover, C. A. *Keys to Infinity*. New York: Wiley, pp. 97–102, 1995.

## Apocalyptic Number

A number of the form  $2^n$  which contains the digits 666 (the BEAST NUMBER) is called an APOCALYPTIC NUMBER.  $2^{157}$  is an apocalyptic number. The first few such powers are 157, 192, 218, 220, ... (Sloane's A007356).

## Apodization

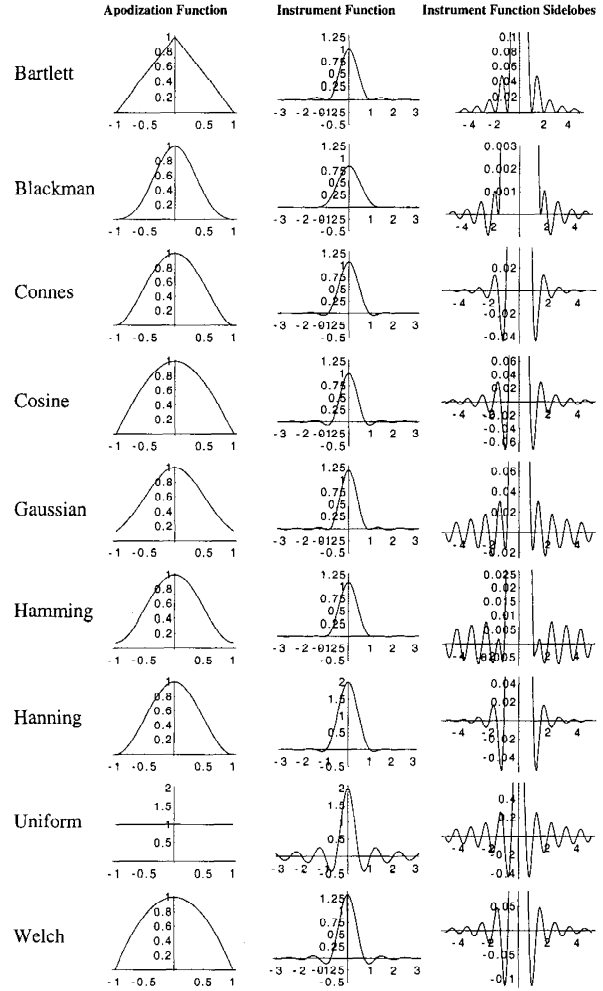

The application of an APODIZATION FUNCTION.

## Apodization Function

A function (also called a TAPERING FUNCTION) used to bring an interferogram smoothly down to zero at the edges of the sampled region. This suppresses sidelobes which would otherwise be produced, but at the expense of widening the lines and therefore decreasing the resolution.

The following are apodization functions for symmetrical (2-sided) interferograms, together with the INSTRUMENT FUNCTIONS (or APPARATUS FUNCTIONS) they produce and a blowup of the INSTRUMENT FUNCTION sidelobes. The INSTRUMENT FUNCTION  $I(k)$  corresponding to a given apodization function  $A(x)$  can be computed by taking the finite FOURIER COSINE TRANSFORM,

$$I(k) = \int_{-a}^a \cos(2\pi kx) A(x) dx. \quad (1)$$

Type	Apodization Function	Instrument Function
Bartlett	$1 - \frac{ x }{a}$	$a \operatorname{sinc}^2(\pi ka)$
Blackman	$B_A(x)$	$B_I(k)$
Connes	$\left(1 - \frac{x^2}{a^2}\right)^2$	$8a\sqrt{2\pi} \frac{J_{5/2}(2\pi ka)}{(2\pi ka)^{5/2}}$
Cosine	$\cos\left(\frac{\pi x}{2a}\right)$	$\frac{4a \cos(2\pi ka)}{\pi(1-16a^2k^2)}$
Gaussian	$e^{-x^2/(2\sigma^2)}$	$2 \int_0^a \cos(2\pi kx) e^{-x^2/(2\sigma^2)} dx$
Hamming	$Hm_A(x)$	$Hm_I(k)$
Hanning	$Hn_A(x)$	$Hn_I(k)$
Uniform	1	$2a \operatorname{sinc}(2\pi ka)$
Welch	$1 - \frac{x^2}{a^2}$	$W_I(k)$

where

$$B_A(x) = 0.42 + 0.5 \cos\left(\frac{\pi x}{a}\right) + 0.08 \cos\left(\frac{2\pi x}{a}\right) \quad (2)$$

$$B_I(k) = \frac{a(0.84 - 0.36a^2k^2 - 2.17 \times 10^{-10}a^4k^4) \operatorname{sinc}(2\pi ak)}{(1 - a^2k^2)(1 - 4a^2k^2)} \quad (3)$$

$$Hm_A(x) = 0.54 + 0.46 \cos\left(\frac{\pi x}{a}\right) \quad (4)$$

$$Hm_I(k) = \frac{a(1.08 - 0.64a^2k^2) \operatorname{sinc}(2\pi ak)}{1 - 4a^2k^2} \quad (5)$$

$$Hn_A(x) = \cos^2 \left( \frac{\pi x}{2a} \right) \quad (6)$$

$$= \frac{1}{2} \left[ 1 + \cos \left( \frac{\pi x}{a} \right) \right] \quad (7)$$

$$Hn_I(k) = \frac{a \operatorname{sinc}(2\pi ak)}{1 - 4a^2 k^2} \quad (8)$$

$$= a[\operatorname{sinc}(2\pi ka) + \frac{1}{2} \operatorname{sinc}(2\pi ka - \pi) + \frac{1}{2} \operatorname{sinc}(2\pi ka + \pi)] \quad (9)$$

$$W_I(k) = a2\sqrt{2\pi} \frac{J_{3/2}(2\pi ka)}{(2\pi ka)^{3/2}} \quad (10)$$

$$= a \frac{\sin(2\pi ka) - 2\pi ak \cos(2\pi ka)}{2a^3 k^3 \pi^3}. \quad (11)$$

Type	IF FWHM	IF Peak	Peak (−) S.L. Peak	Peak (+) S.L. Peak
Bartlett	1.77179	1	0.00000000	0.0471904

Cosine	1.63941	$\frac{4}{\pi}$	−0.0708048	0.0292720
Gaussian	—	1	—	—
Hamming	1.81522	1.08	−0.00689132	0.00734934
Hanning	2.00000	1	−0.0267076	0.00843441
Uniform	1.20671	2	−0.217234	0.128375
Welch	1.59044	$\frac{4}{3}$	−0.0861713	0.356044

A general symmetric apodization function  $A(x)$  can be written as a FOURIER SERIES

$$A(x) = a_0 + 2 \sum_{n=1}^{\infty} a_n \cos \left( \frac{n\pi x}{b} \right), \quad (12)$$

where the COEFFICIENTS satisfy

$$a_0 + 2 \sum_{n=1}^{\infty} a_n = 1. \quad (13)$$

The corresponding apparatus function is

$$I(t) \equiv \int_{-b}^b A(x) e^{-2\pi i k x} dx = 2b \left\{ a_0 \operatorname{sinc}(2\pi kb) + \sum_{n=1}^{\infty} [\operatorname{sinc}(2\pi kb + n\pi) + \operatorname{sinc}(2\pi kb - n\pi)] \right\}. \quad (14)$$

To obtain an APODIZATION FUNCTION with zero at  $ka = 3/4$ , use

$$a_0 \operatorname{sinc}(\frac{3}{2}\pi) + a_1 [\operatorname{sinc}(\frac{5}{2}\pi) + \operatorname{sinc}(\frac{1}{2}\pi)] = 0. \quad (15)$$

Plugging in (13),

$$-(1 - 2a_1) \frac{2}{3\pi} + a_1 \left( \frac{2}{5\pi} + \frac{2}{\pi} \right) = -\frac{1}{3}(1 - 2a_1) + a_1 \left( \frac{1}{5} + 1 \right) = 0 \quad (16)$$

$$a_1 \left( \frac{6}{5} + \frac{2}{3} \right) = \frac{1}{3} \quad (17)$$

$$a_1 = \frac{\frac{1}{3}}{\frac{6}{5} + \frac{2}{3}} = \frac{5}{6 \cdot 3 + 2 \cdot 5} = \frac{5}{28} \quad (18)$$

$$a_0 = 1 - 2a_1 = \frac{28 - 2 \cdot 5}{28} = \frac{18}{28} = \frac{9}{14}. \quad (19)$$

The HAMMING FUNCTION is close to the requirement that the APPARATUS FUNCTION goes to 0 at  $ka = 5/4$ , giving

$$a_0 = \frac{25}{46} \approx 0.5435 \quad (20)$$

$$a_1 = \frac{21}{92} \approx 0.2283. \quad (21)$$

The BLACKMAN FUNCTION is chosen so that the APPARATUS FUNCTION goes to 0 at  $ka = 5/4$  and  $9/4$ , giving

$$a_0 = \frac{3969}{9304} \approx 0.4266 \quad (22)$$

$$a_1 = \frac{1155}{4652} \approx 0.2483 \quad (23)$$

$$a_2 = \frac{715}{18608} \approx 0.0384. \quad (24)$$

#### Apollonius Circles

There are two completely different definitions of the so-called Apollonius circles:

1. The set of all points whose distances from two fixed points are in a constant ratio  $1 : \mu$  (Ogilvy 1990).

2. The eight CIRCLES (two of which are nondegenerate) which solve APOLLONIUS' PROBLEM for three CIRCLES.

Given one side of a TRIANGLE and the ratio of the lengths of the other two sides, the LOCUS of the third VERTEX is the Apollonius circle (of the first type) whose CENTER is on the extension of the given side. For a given TRIANGLE, there are three circles of Apollonius.

Denote the three Apollonius circles (of the first type) of a TRIANGLE by  $k_1$ ,  $k_2$ , and  $k_3$ , and their centers  $L_1$ ,  $L_2$ , and  $L_3$ . The center  $L_1$  is the intersection of the side  $A_2A_3$  with the tangent to the CIRCUMCIRCLE at  $A_1$ .  $L_1$  is also the pole of the SYMMEDIAN POINT  $K$  with respect to CIRCUMCIRCLE. The centers  $L_1$ ,  $L_2$ , and  $L_3$  are COLLINEAR on the POLAR of  $K$  with regard to its CIRCUMCIRCLE, called the LEMOINE LINE. The circle of Apollonius  $k_1$  is also the locus of a point whose PEDAL TRIANGLE is ISOSCELES such that  $\overline{P_1P_2} = \overline{P_1P_3}$ .

Let  $U$  and  $V$  be points on the side line  $BC$  of a TRIANGLE  $\triangle ABC$  met by the interior and exterior ANGLE BISECTORS of ANGLES  $A$ . The CIRCLE with DIAMETER  $UV$  is called the  $A$ -Apollonian circle. Similarly, construct the  $B$ - and  $C$ -Apollonian circles. The Apollonian circles pass through the VERTICES  $A$ ,  $B$ , and  $C$ , and through the two ISODYNAMIC POINTS  $S$  and  $S'$ . The VERTICES of the D-TRIANGLE lie on the respective Apollonius circles.

#### Apollonius Point

Consider the EXCIRCLES  $\Gamma_A$ ,  $\Gamma_B$ , and  $\Gamma_C$  of a TRIANGLE, and the CIRCLE  $\Gamma$  internally TANGENT to all three. Denote the contact point of  $\Gamma$  and  $\Gamma_A$  by  $A'$ , etc. Then

the LINES  $AA'$ ,  $BB'$ , and  $CC'$  CONCUR in this point. It has TRIANGLE CENTER FUNCTION

$$\alpha = \sin^2 A \cos^2 \left[ \frac{1}{2}(B - C) \right].$$

#### Apollonius' Problem

Given three objects, each of which may be a POINT, LINE, or CIRCLE, draw a CIRCLE that is TANGENT to each. There are a total of ten cases. The two easiest involve three points or three LINES, and the hardest involves three CIRCLES. Euclid solved the two easiest cases in his *Elements*, and the others (with the exception of the three CIRCLE problem), appeared in the *Tangencies* of Apollonius which was, however, lost. The general problem is, in principle, solvable by STRAIGHTEDGE and COMPASS alone.

The three-CIRCLE problem was solved by Viète (Boyer 1968), and the solutions are called APOLLONIUS CIRCLES. There are eight total solutions. The simplest solution is obtained by solving the three simultaneous quadratic equations

$$(x - x_1)^2 + (y - y_1)^2 - (r \pm r_1)^2 = 0 \quad (1)$$

$$(x - x_2)^2 + (y - y_2)^2 - (r \pm r_2)^2 = 0 \quad (2)$$

$$(x - x_3)^2 + (y - y_3)^2 - (r \pm r_3)^2 = 0 \quad (3)$$

in the three unknowns  $x$ ,  $y$ ,  $r$  for the eight triplets of signs (Courant and Robbins 1996). Expanding the equations gives

$$(x^2 + y^2 - r^2) - 2xx_i - 2yy_i \pm 2rr_i + (x_i^2 + y_i^2 - r_i^2) = 0 \quad (4)$$

for  $i = 1, 2, 3$ . Since the first term is the same for each equation, taking (2) - (1) and (3) - (1) gives

$$ax + by + cr = d \quad (5)$$

$$a'x + b'y + c'r = d', \quad (6)$$

where

$$a = 2(x_1 - x_2) \quad (7)$$

$$b = 2(y_1 - y_2) \quad (8)$$

$$c = \mp 2(r_1 - r_2) \quad (9)$$

$$d = (x_2^2 + y_2^2 - r_2^2) - (x_1^2 + y_1^2 - r_1^2) \quad (10)$$

and similarly for  $a'$ ,  $b'$ ,  $c'$  and  $d'$  (where the 2 subscripts are replaced by 3s). Solving these two simultaneous linear equations gives

$$x = \frac{b'd - bd' - b'cr + bc'r}{ab' - ba'} \quad (11)$$

$$y = \frac{-a'd + ad' + a'cr - ac'r}{ab' - a'b}, \quad (12)$$

which can then be plugged back into the QUADRATIC EQUATION (1) and solved using the QUADRATIC FORMULA.

Perhaps the most elegant solution is due to Gergonne. It proceeds by locating the six HOMOTHETIC CENTERS (three internal and three external) of the three given CIRCLES. These lie three by three on four lines (illustrated above). Determine the POLES of one of these with respect to each of the three CIRCLES and connect the POLES with the RADICAL CENTER of the CIRCLES. If the connectors meet, then the three pairs of intersections are the points of tangency of two of the eight circles (Johnson 1929, Dörrie 1965). To determine which two of the eight Apollonius circles are produced by the three pairs, simply take the two which intersect the original three CIRCLES only in a single point of tangency. The procedure, when repeated, gives the other three pairs of CIRCLES.

If the three CIRCLES are mutually tangent, then the eight solutions collapse to two, known as the SODDY CIRCLES.

#### Apollonius Pursuit Problem

Given a ship with a known constant direction and speed  $v$ , what course should be taken by a chase ship in pursuit (traveling at speed  $V$ ) in order to intersect the other ship in as short a time as possible? The problem can be solved by finding all points which can be simultaneously reached by both ships, which is an APOLLONIUS CIRCLE with  $\mu = v/V$ . If the CIRCLE cuts the path of the pursued ship, the intersection is the point towards which

the pursuit ship should steer. If the CIRCLE does not cut the path, then it cannot be caught.

### Apollonius Theorem

$$ma_2^2 + na_3^2 = (m+n)\overline{A_1P}^2 + m\overline{PA_3}^2 + n\overline{PA_2}^2.$$

### Apothem

Given a CIRCLE, the PERPENDICULAR distance  $a$  from the MIDPOINT of a CHORD to the CIRCLE's center is called the apothem. It is also equal to the RADIUS  $r$  minus the SAGITTA  $s$ ,

$$a = r - s.$$

see also CHORD, RADIUS, SAGITTA, SECTOR, SEGMENT

### Apparatus Function

see INSTRUMENT FUNCTION

### Appell Hypergeometric Function

A formal extension of the HYPERGEOMETRIC FUNCTION to two variables, resulting in four kinds of functions (Appell 1925),

$$F_1(\alpha; \beta, \beta'; \gamma; x, y) = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{(\alpha)_{m+n} (\beta)_m (\beta')_n}{m! n! (\gamma)_{m+n}} x^m y^n$$

$$F_2(\alpha; \beta, \beta'; \gamma, \gamma'; x, y) = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{(\alpha)_{m+n} (\beta)_m (\beta')_n}{m! n! (\gamma)_m (\gamma')_n} x^m y^n$$

$$F_3(\alpha, \alpha'; \beta, \beta'; \gamma; x, y) = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{(\alpha)_m (\alpha')_n (\beta)_m (\beta')_n}{m! n! (\gamma)_{m+n}} x^m y^n$$

$$F_4(\alpha; \beta; \gamma, \gamma'; x, y) = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{(\alpha)_{m+n} (\beta)_{m+n}}{m! n! (\gamma)_m (\gamma')_n} x^m y^n.$$

Appell defined the functions in 1880, and Picard showed in 1881 that they may all be expressed by INTEGRALS of the form

$$\int_0^1 u^\alpha (1-u)^\beta (1-xu)^\gamma (1-yu)^\delta du.$$

### Appell Polynomial

A type of POLYNOMIAL which includes the BERNOULLI POLYNOMIAL, HERMITE POLYNOMIAL, and LAGUERRE POLYNOMIAL as special cases. The series of POLYNOMIALS  $\{A_n(z)\}_{n=0}^{\infty}$  is defined by

$$A(t)e^{zt} = \sum_{n=0}^{\infty} A_n(z)t^n,$$

where

$$A(t) = \sum_{k=0}^{\infty} a_k t^k$$

is a formal POWER series with  $k = 0, 1, \dots$  and  $a_0 \neq 0$ .

### Appell Transformation

A HOMOGRAPHIC transformation

$$x_1 = \frac{ax + by + c}{a''x + b''y + c}$$

$$y_1 = \frac{a'x + b'y + c'}{a''x + b''y + c''}$$

with  $t_1$  substituted for  $t$  according to

$$k dt_1 = \frac{dt}{(a''x + b''y + c'')^2}.$$

## Apple

A SURFACE OF REVOLUTION defined by Kepler. It consists of more than half of a circular ARC rotated about an axis passing through the endpoints of the ARC. The equations of the upper and lower boundaries in the  $x$ - $z$  PLANE are

$$z_{\pm} = \pm \sqrt{R^2 - (x - r)^2}$$

for  $R > r$  and  $x \in [-(r + R), r + R]$ . It is the outside surface of a SPINDLE TORUS.

see also BUBBLE, LEMON, SPHERE-SPHERE INTERSECTION, SPINDLE TORUS

## Approximately Equal

If two quantities  $A$  and  $B$  are approximately equal, this is written  $A \approx B$ .

see also DEFINED, EQUAL

## Approximation Theory

The mathematical study of how given quantities can be approximated by other (usually simpler) ones under appropriate conditions. Approximation theory also studies the size and properties of the ERROR introduced by approximation. Approximations are often obtained by POWER SERIES expansions in which the higher order terms are dropped.

see also LAGRANGE REMAINDER

## Arakelov Theory

A formal mathematical theory which introduces "components at infinity" by defining a new type of divisor class group of INTEGERS of a NUMBER FIELD. The divisor class group is called an "arithmetic surface."

see also ARITHMETIC GEOMETRY

## Arbelos

The term "arbelos" means SHOEMAKER'S KNIFE in Greek, and this term is applied to the shaded AREA in the above figure which resembles the blade of a knife used by ancient cobblers (Gardner 1979). Archimedes himself is believed to have been the first mathematician to study the mathematical properties of this figure. The position of the central notch is arbitrary and can be located anywhere along the DIAMETER.

The arbelos satisfies a number of unexpected identities (Gardner 1979).

1. Call the radii of the left and right SEMICIRCLES  $a$  and  $b$ , respectively, with  $a + b \equiv R$ . Then the arc length along the bottom of the arbelos is

$$L = 2\pi a + 2\pi b = 2\pi(a + b) = 2\pi R,$$

so the arc lengths along the top and bottom of the arbelos are the same.

2. Draw the PERPENDICULAR  $BD$  from the tangent of the two SEMICIRCLES to the edge of the large CIRCLE. Then the AREA of the arbelos is the same as the AREA of the CIRCLE with DIAMETER  $BD$ .
3. The CIRCLES  $C_1$  and  $C_2$  inscribed on each half of  $BD$  on the arbelos (called ARCHIMEDES' CIRCLES) each have DIAMETER  $(AB)(BC)/(AC)$ . Furthermore, the smallest CIRCUMCIRCLE of these two circles has an area equal to that of the arbelos.
4. The line tangent to the semicircles  $AB$  and  $BC$  contains the point  $E$  and  $F$  which lie on the lines  $AD$  and  $CD$ , respectively. Furthermore,  $BD$  and  $EF$  bisect each other, and the points  $B$ ,  $D$ ,  $E$ , and  $F$  are CONCYCLIC.

5. In addition to the ARCHIMEDES' CIRCLES  $C_1$  and  $C_2$  in the arbelos figure, there is a third circle  $C_3$  called the BANKOFF CIRCLE which is congruent to these two.

6. Construct a chain of TANGENT CIRCLES starting with the CIRCLE TANGENT to the two small ones and large one. The centers of the CIRCLES lie on an ELLIPSE, and the DIAMETER of the  $n$ th CIRCLE  $C_n$  is  $(1/n)$ th PERPENDICULAR distance to the base of the SEMICIRCLE. This result is most easily proven using INVERSION, but was known to Pappus, who referred to it as an ancient theorem (Hood 1961, Cadwell 1966, Gardner 1979, Bankoff 1981). If  $r \equiv AB/AC$ , then the radius of the  $n$ th circle in the PAPPUS CHAIN is

$$r_n = \frac{(1-r)r}{2[n^2(1-r)^2 + r]}.$$

This general result simplifies to  $r_n = 1/(6+n^2)$  for  $r = 2/3$  (Gardner 1979). Further special cases when  $AC = 1 + AB$  are considered by Gaba (1940).

7. If  $B$  divides  $AC$  in the GOLDEN RATIO  $\phi$ , then the circles in the chain satisfy a number of other special properties (Bankoff 1955).

#### Arborescence

A DIGRAPH is called an arborescence if, from a given node  $x$  known as the ROOT, there is exactly one elementary path from  $x$  to every other node  $y$ .

see also ARBORICITY

#### Arboricity

Given a GRAPH  $G$ , the arboricity is the MINIMUM number of line-disjoint acyclic SUBGRAPHS whose UNION is  $G$ .

see also ANARBORICITY

#### Arc

In general, any smooth curve joining two points. In particular, any portion (other than the entire curve) of a CIRCLE or ELLIPSE.

see also APPLE, CIRCLE-CIRCLE INTERSECTION, FIVE DISKS PROBLEM, FLOWER OF LIFE, LEMON, LENS, PIECEWISE CIRCULAR CURVE, REULEAUX POLYGON, REULEAUX TRIANGLE, SALINON, SEED OF LIFE, TRIANGLE ARCS, VENN DIAGRAM, YIN-YANG

#### Arc Length

Arc length is defined as the length along a curve,

$$s \equiv \int_a^b |d\ell|. \quad (1)$$

Defining the line element  $ds^2 \equiv |d\ell|^2$ , parameterizing the curve in terms of a parameter  $t$ , and noting that

$ds/dt$  is simply the magnitude of the VELOCITY with which the end of the RADIUS VECTOR  $\mathbf{r}$  moves gives

$$s = \int_a^b ds = \int_a^b \frac{ds}{dt} dt = \int_a^b |\mathbf{r}'(t)| dt. \quad (2)$$

In POLAR COORDINATES,

$$d\ell = \hat{\mathbf{r}} dr + r\hat{\theta} d\theta = \left( \frac{dr}{d\theta} \hat{\mathbf{r}} + r\hat{\theta} \right) d\theta, \quad (3)$$

so

$$ds = |d\ell| = \sqrt{r^2 + \left( \frac{dr}{d\theta} \right)^2} d\theta \quad (4)$$

$$s = \int_{\theta_1}^{\theta_2} |d\ell| = \int_{\theta_1}^{\theta_2} \sqrt{r^2 + \left( \frac{dr}{d\theta} \right)^2} d\theta. \quad (5)$$

In CARTESIAN COORDINATES,

$$d\ell = x\hat{\mathbf{x}} + y\hat{\mathbf{y}} \quad (6)$$

$$ds = \sqrt{dx^2 + dy^2} = \sqrt{\left( \frac{dy}{dx} \right)^2 + 1} dx. \quad (7)$$

Therefore, if the curve is written

$$\mathbf{r}(x) = x\hat{\mathbf{x}} + f(x)\hat{\mathbf{y}}, \quad (8)$$

then

$$s = \int_a^b \sqrt{1 + f'^2(x)} dx. \quad (9)$$

If the curve is instead written

$$\mathbf{r}(t) = x(t)\hat{\mathbf{x}} + y(t)\hat{\mathbf{y}}, \quad (10)$$

then

$$s = \int_a^b \sqrt{x'^2(t) + y'^2(t)} dt. \quad (11)$$

Or, in three dimensions,

$$\mathbf{r}(t) = x(t)\hat{\mathbf{x}} + y(t)\hat{\mathbf{y}} + z(t)\hat{\mathbf{z}}, \quad (12)$$

so

$$s = \int_a^b \sqrt{x'^2(t) + y'^2(t) + z'^2(t)} dt. \quad (13)$$

### Archimedes Algorithm

Successive application of ARCHIMEDES' RECURRENCE FORMULA gives the Archimedes algorithm, which can be used to provide successive approximations to  $\pi$  (PI). The algorithm is also called the BORCHARDT-PFAFF ALGORITHM. Archimedes obtained the first rigorous approximation of  $\pi$  by CIRCUMSCRIBING and INSCRIBING  $n = 6 \cdot 2^k$ -gons on a CIRCLE. From ARCHIMEDES' RECURRENCE FORMULA, the CIRCUMFERENCES  $a$  and  $b$  of the circumscribed and inscribed POLYGONS are

$$a(n) = 2n \tan \left( \frac{\pi}{n} \right) \quad (1)$$

$$b(n) = 2n \sin \left( \frac{\pi}{n} \right), \quad (2)$$

where

$$b(n) < C = 2\pi r = 2\pi \cdot 1 = 2\pi < a(n). \quad (3)$$

For a HEXAGON,  $n = 6$  and

$$a_0 \equiv a(6) = 4\sqrt{3} \quad (4)$$

$$b_0 \equiv b(6) = 6, \quad (5)$$

where  $a_k \equiv a(6 \cdot 2^k)$ . The first iteration of ARCHIMEDES' RECURRENCE FORMULA then gives

$$a_1 = \frac{2 \cdot 6 \cdot 4\sqrt{3}}{6 + 4\sqrt{3}} = \frac{24\sqrt{3}}{3 + 2\sqrt{3}} = 24(2 - \sqrt{3}) \quad (6)$$

$$\begin{aligned} b_1 &= \sqrt{24(2 - \sqrt{3}) \cdot 6} = 12\sqrt{2 - \sqrt{3}} \\ &= 6(\sqrt{6} - \sqrt{2}). \end{aligned} \quad (7)$$

Additional iterations do not have simple closed forms, but the numerical approximations for  $k = 0, 1, 2, 3, 4$  (corresponding to 6-, 12-, 24-, 48-, and 96-gons) are

$$3.00000 < \pi < 3.46410 \quad (8)$$

$$3.10583 < \pi < 3.21539 \quad (9)$$

$$3.13263 < \pi < 3.15966 \quad (10)$$

$$3.13935 < \pi < 3.14609 \quad (11)$$

$$3.14103 < \pi < 3.14271. \quad (12)$$

By taking  $k = 4$  (a 96-gon) and using strict inequalities to convert irrational bounds to rational bounds at each step, Archimedes obtained the slightly looser result

$$\frac{223}{71} = 3.14084 \dots < \pi < \frac{22}{7} = 3.14285 \dots \quad (13)$$

### Archimedes' Axiom

An AXIOM actually attributed to Eudoxus (Boyer 1968) which states that

$$a/b = c/d$$

IFF the appropriate one of following conditions is satisfied for INTEGERS  $m$  and  $n$ :

1. If  $ma < nb$ , then  $mc < md$ .
2. If  $ma = nb$ , then  $mc = nd$ .
3. If  $ma > nb$ , then  $mc > nd$ .

ARCHIMEDES' LEMMA is sometimes also known as Archimedes' axiom.

### Archimedes' Cattle Problem

Also called the BOVINUM PROBLEMA. It is stated as follows: "The sun god had a herd of cattle consisting of bulls and cows, one part of which was white, a second black, a third spotted, and a fourth brown. Among the bulls, the number of white ones was one half plus one third the number of the black greater than the brown; the number of the black, one quarter plus one fifth the number of the spotted greater than the brown; the number of the spotted, one sixth and one seventh the number of the white greater than the brown. Among the cows, the number of white ones was one third plus one quarter of the total black cattle; the number of the black, one quarter plus one fifth the total of the spotted cattle; the number of spotted, one fifth plus one sixth the total of the brown cattle; the number of the brown, one sixth plus one seventh the total of the white cattle. What was the composition of the herd?"

Solution consists of solving the simultaneous DIOPHANTINE EQUATIONS in INTEGERS  $W, X, Y, Z$  (the number of white, black, spotted, and brown bulls) and  $w, x, y, z$  (the number of white, black, spotted, and brown cows),

$$W = \frac{5}{6}X + Z \quad (1)$$

$$X = \frac{9}{20}Y + Z \quad (2)$$

$$Y = \frac{13}{42}W + Z \quad (3)$$

$$w = \frac{7}{12}(X + x) \quad (4)$$

$$x = \frac{9}{20}(Y + y) \quad (5)$$

$$y = \frac{11}{30}(Z + z) \quad (6)$$

$$z = \frac{13}{42}(W + w). \quad (7)$$

The smallest solution in INTEGERS is

$$W = 10,366,482 \quad (8)$$

$$X = 7,460,514 \quad (9)$$

$$Y = 7,358,060 \quad (10)$$

$$Z = 4,149,387 \quad (11)$$

$$w = 7,206,360 \quad (12)$$

$$x = 4,893,246 \quad (13)$$

$$y = 3,515,820 \quad (14)$$

$$z = 5,439,213. \quad (15)$$

A more complicated version of the problem requires that  $W+X$  be a SQUARE NUMBER and  $Y+Z$  a TRIANGULAR NUMBER. The solution to this PROBLEM are numbers with 206544 or 206545 digits.

see  $\pi$

**Archimedes' Hat-Box Theorem**

Enclose a SPHERE in a CYLINDER and slice PERPENDICULARLY to the CYLINDER's axis. Then the SURFACE AREA of the of SPHERE slice is equal to the SURFACE AREA of the CYLINDER slice.

**Archimedes' Lemma**

Also known as the continuity axiom, this LEMMA survives in the writings of Eudoxus (Boyer 1968). It states that, given two magnitudes having a ratio, one can find a multiple of either which will exceed the other. This principle was the basis for the EXHAUSTION METHOD which Archimedes invented to solve problems of AREA and VOLUME.

see ARCHIMEDES' LEMMA

**Archimedes' Problem**

Cut a SPHERE by a PLANE in such a way that the VOLUMES of the SPHERICAL SEGMENTS have a given RATIO.

see also SPHERICAL SEGMENT

**Archimedes' Recurrence Formula**

Let  $a_n$  and  $b_n$  be the PERIMETERS of the CIRCUMSCRIBED and INSCRIBED  $n$ -gon and  $a_{2n}$  and  $b_{2n}$  the PERIMETERS of the CIRCUMSCRIBED and INSCRIBED  $2n$ -gon. Then

$$a_{2n} = \frac{2a_n b_n}{a_n + b_n} \quad (1)$$

$$b_{2n} = \sqrt{a_{2n} b_n}. \quad (2)$$

The first follows from the fact that side lengths of the POLYGONS on a CIRCLE of RADIUS  $r = 1$  are

$$s_R = 2 \tan \left( \frac{\pi}{n} \right) \quad (3)$$

$$s_r = 2 \sin \left( \frac{\pi}{n} \right), \quad (4)$$

so

$$a_n = 2n \tan \left( \frac{\pi}{n} \right) \quad (5)$$

$$b_n = 2n \sin \left( \frac{\pi}{n} \right). \quad (6)$$

But

$$\begin{aligned} \frac{2a_n b_n}{a_n + b_n} &= \frac{2 \cdot 2n \tan \left( \frac{\pi}{n} \right) \cdot 2n \sin \left( \frac{\pi}{n} \right)}{2n \tan \left( \frac{\pi}{n} \right) + 2n \sin \left( \frac{\pi}{n} \right)} \\ &= 4n \frac{\tan \left( \frac{\pi}{n} \right) \sin \left( \frac{\pi}{n} \right)}{\tan \left( \frac{\pi}{n} \right) + \sin \left( \frac{\pi}{n} \right)}. \end{aligned} \quad (7)$$

Using the identity

$$\tan \left( \frac{1}{2} x \right) = \frac{\tan x \sin x}{\tan x + \sin x} \quad (8)$$

then gives

$$\frac{2a_n b_n}{a_n + b_n} = 4n \tan \left( \frac{\pi}{2n} \right) = a_{2n}. \quad (9)$$

The second follows from

$$\sqrt{a_{2n}b_n} = \sqrt{4n \tan\left(\frac{\pi}{2n}\right) \cdot 2n \sin\left(\frac{\pi}{n}\right)} \quad (10)$$

Using the identity

$$\sin x = 2 \sin\left(\frac{1}{2}x\right) \cos\left(\frac{1}{2}x\right) \quad (11)$$

gives

$$\begin{aligned} \sqrt{a_{2n}b_n} &= 2n \sqrt{2 \tan\left(\frac{\pi}{2n}\right) \cdot 2 \sin\left(\frac{\pi}{2n}\right) \cos\left(\frac{\pi}{2n}\right)} \\ &= 4n \sqrt{\sin^2\left(\frac{\pi}{2n}\right)} = 4n \sin\left(\frac{\pi}{2n}\right) = b_{2n}. \end{aligned} \quad (12)$$

Successive application gives the ARCHIMEDES ALGORITHM, which can be used to provide successive approximations to  $\text{PI}(\pi)$ .

see also ARCHIMEDES ALGORITHM, PI

#### Archimedean Solid

The Archimedean solids are convex POLYHEDRA which have a similar arrangement of nonintersecting regular plane CONVEX POLYGONS of two or more different types about each VERTEX with all sides the same length. The Archimedean solids are distinguished from the PRISMS, ANTIPRISMS, and ELONGATED SQUARE GYROBICUPOLA by their symmetry group: the Archimedean solids have a spherical symmetry, while the others have “dihedral” symmetry. The Archimedean solids are sometimes also referred to as the SEMIREGULAR POLYHEDRA.

Pugh (1976, p. 25) points out the Archimedean solids are all capable of being circumscribed by a regular TETRAHEDRON so that four of their faces lie on the faces of that TETRAHEDRON. A method of constructing the Archimedean solids using a method known as “expansion” has been enumerated by Stott (Stott 1910; Ball and Coxeter 1987, pp. 139–140).

Let the cyclic sequence  $S = (p_1, p_2, \dots, p_q)$  represent the degrees of the faces surrounding a vertex (i.e.,  $S$  is a list of the number of sides of all polygons surrounding any vertex). Then the definition of an Archimedean solid requires that the sequence must be the same for each vertex to within ROTATION and REFLECTION. Walsh (1972) demonstrates that  $S$  represents the degrees of the faces surrounding each vertex of a semiregular convex polyhedron or TESSELLATION of the plane IFF

1.  $q \geq 3$  and every member of  $S$  is at least 3,
2.  $\sum_{i=1}^q \frac{1}{p_i} \geq \frac{1}{2}q - 1$ , with equality in the case of a plane TESSELLATION, and

3. for every ODD NUMBER  $p \in S$ ,  $S$  contains a subsequence  $(b, p, b)$ .

Condition (1) simply says that the figure consists of two or more polygons, each having at least three sides. Condition (2) requires that the sum of interior angles at a vertex must be equal to a full rotation for the figure to lie in the plane, and less than a full rotation for a solid figure to be convex.

The usual way of enumerating the semiregular polyhedra is to eliminate solutions of conditions (1) and (2) using several classes of arguments and then prove that the solutions left are, in fact, semiregular (Kepler 1864, pp. 116–126; Catalan 1865, pp. 25–32; Coxeter 1940, p. 394; Coxeter *et al.* 1954; Lines 1965, pp. 202–203; Walsh 1972). The following table gives all possible regular and semiregular polyhedra and tessellations. In the table, ‘P’ denotes PLATONIC SOLID, ‘M’ denotes a PRISM or ANTIPRISM, ‘A’ denotes an Archimedean solid, and ‘T’ a plane tessellation.

As shown in the above table, there are exactly 13 Archimedean solids (Walsh 1972, Ball and Coxeter 1987).

They are called the CUBOCTAHEDRON, GREAT RHOMBICOSIDODECAHEDRON, GREAT RHOMBICUBOCTAHEDRON, ICOSIDODECAHEDRON, SMALL RHOMBICOSIDODECAHEDRON, SMALL RHOMBICUBOCTAHEDRON, SNUB CUBE, SNUB DODECAHEDRON, TRUNCATED CUBE, TRUNCATED DODECAHEDRON, TRUNCATED ICOSAHE-  
DRON (soccer ball), TRUNCATED OCTAHEDRON, and TRUNCATED TETRAHEDRON. The Archimedean solids satisfy

$$(2\pi - \sigma)V = 4\pi,$$

where  $\sigma$  is the sum of face-angles at a vertex and  $V$  is the number of vertices (Steinitz and Rademacher 1934, Ball and Coxeter 1987).

Here are the Archimedean solids shown in alphabetical order (left to right, then continuing to the next row).

The following table lists the symbol and number of faces of each type for the Archimedean solids (Wenninger 1989, p. 9).

truncated cube	1.63828	1.70711	1.77882
truncated dodecahedron	2.88526	2.92705	2.96945
truncated icosahedron	2.37713	2.42705	2.47802
truncated octahedron	1.42302	1.5	1.58114
truncated tetrahedron	0.95940	1.06066	1.17260

The DUALS of the Archimedean solids, sometimes called the CATALAN SOLIDS, are given in the following table.

Archimedean Solid	Dual
rhombicosidodecahedron	deltoidal hexecontahedron
small rhombicuboctahedron	deltoidal icositetrahedron
great rhombicuboctahedron	disdyakis dodecahedron
great rhombicosidodecahedron	disdyakis triacontahedron
truncated icosahedron	pentakis dodecahedron
snub dodecahedron (laevo)	pentagonal hexecontahedron (dextro)
snub cube (laevo)	pentagonal icositetrahedron (dextro)
cuboctahedron	rhombic dodecahedron
icosidodecahedron	rhombic triacontahedron
truncated octahedron	tetrakis hexahedron
truncated dodecahedron	triakis icosahedron
truncated cube	triakis octahedron
truncated tetrahedron	triakis tetrahedron

Here are the Archimedean DUALS (Holden 1971, Pearce 1978) displayed in alphabetical order (left to right, then continuing to the next row).

Here are the Archimedean solids paired with their DUALS.

The Archimedean solids and their DUALS are all CANONICAL POLYHEDRA.

### Archimedean Spiral

A SPIRAL with POLAR equation

$$r = a\theta^{1/m},$$

where  $r$  is the radial distance,  $\theta$  is the polar angle, and  $m$  is a constant which determines how tightly the spiral is "wrapped." The CURVATURE of an Archimedean spiral is given by

$$\kappa = \frac{n\theta^{1-1/n}(1+n+n^2\theta^2)}{a(1+n^2\theta^2)^{3/2}}.$$

Various special cases are given in the following table.

Name	$m$
lituus	−2
hyperbolic spiral	−1
Archimedes' spiral	1
Fermat's spiral	2

see also ARCHIMEDES' SPIRAL, DAISY, FERMAT'S SPIRAL, HYPERBOLIC SPIRAL, LITUUS, SPIRAL

### Archimedean Spiral Inverse Curve

The INVERSE CURVE of the ARCHIMEDEAN SPIRAL

$$r = a\theta^{1/m}$$

with INVERSION CENTER at the origin and inversion RADIUS  $k$  is the ARCHIMEDEAN SPIRAL

$$r = ka\theta^{1/m}.$$

### Archimedes' Spiral

An ARCHIMEDEAN SPIRAL with POLAR equation

$$r = a\theta.$$

This spiral was studied by Conon, and later by Archimedes in *On Spirals* about 225 BC. Archimedes was able to work out the lengths of various tangents to the spiral.

Archimedes' spiral can be used for COMPASS and STRAIGHTEDGE division of an ANGLE into  $n$  parts (including ANGLE TRISECTION) and can also be used for CIRCLE SQUARING. In addition, the curve can be used as a cam to convert uniform circular motion into uniform linear motion. The cam consists of one arch of the spiral above the  $x$ -AXIS together with its reflection in the  $x$ -AXIS. Rotating this with uniform angular velocity about its center will result in uniform linear motion of the point where it crosses the  $y$ -AXIS.

### Archimedes' Spiral Inverse

Taking the ORIGIN as the INVERSION CENTER, ARCHIMEDES' SPIRAL  $r = a\theta$  inverts to the HYPERBOLIC SPIRAL  $r = a/\theta$ .

### Archimedean Valuation

A VALUATION for which  $|x| \leq 1$  IMPLIES  $|1 + x| \leq C$  for the constant  $C = 1$  (independent of  $x$ ). Such a VALUATION does not satisfy the strong TRIANGLE INEQUALITY

$$|x + y| \leq \max(|x|, |y|).$$

### Arcsecant

see INVERSE SECANT

### Arcsine

see INVERSE SINE

### Arctangent

see INVERSE TANGENT

### Area

The AREA of a SURFACE is the amount of material needed to “cover” it completely. The AREA of a TRIANGLE is given by

$$A_{\Delta} = \frac{1}{2}lh, \quad (1)$$

where  $l$  is the base length and  $h$  is the height, or by HERON'S FORMULA

$$A_{\Delta} = \sqrt{s(s-a)(s-b)(s-c)}, \quad (2)$$

where the side lengths are  $a$ ,  $b$ , and  $c$  and  $s$  the SEMIPERIMETER. The AREA of a RECTANGLE is given by

$$A_{\text{rectangle}} = ab, \quad (3)$$

where the sides are length  $a$  and  $b$ . This gives the special case of

$$A_{\text{square}} = a^2 \quad (4)$$

for the SQUARE. The AREA of a regular POLYGON with  $n$  sides and side length  $s$  is given by

$$A_{n\text{-gon}} = \frac{1}{4}ns^2 \cot\left(\frac{\pi}{n}\right). \quad (5)$$

CALCULUS and, in particular, the INTEGRAL, are powerful tools for computing the AREA between a curve  $f(x)$  and the  $x$ -AXIS over an INTERVAL  $[a, b]$ , giving

$$A = \int_a^b f(x) dx. \quad (6)$$

The AREA of a POLAR curve with equation  $r = r(\theta)$  is

$$A = \frac{1}{2} \int r^2 d\theta. \quad (7)$$

Written in CARTESIAN COORDINATES, this becomes

$$A = \frac{1}{2} \int \left( x \frac{dy}{dt} - y \frac{dx}{dt} \right) dt \quad (8)$$

$$= \frac{1}{2} \int (x dy - y dx). \quad (9)$$

For the AREA of special surfaces or regions, see the entry for that region. The generalization of AREA to 3-D is called VOLUME, and to higher DIMENSIONS is called CONTENT.

see also ARC LENGTH, AREA ELEMENT, CONTENT, SURFACE AREA, VOLUME

#### References

- Gray, A. “The Intuitive Idea of Area on a Surface.” §13.2 in *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 259–260, 1993.

### Area Element

The area element for a SURFACE with RIEMANNIAN METRIC

$$ds^2 = E du^2 + 2F du dv + G dv^2$$

is

$$dA = \sqrt{EG - F^2} du \wedge dv,$$

where  $du \wedge dv$  is the WEDGE PRODUCT.

see also AREA, LINE ELEMENT, RIEMANNIAN METRIC, VOLUME ELEMENT

#### References

- Gray, A. “The Intuitive Idea of Area on a Surface.” §13.2 in *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 259–260, 1993.

### Area-Preserving Map

A MAP  $F$  from  $\mathbb{R}^n$  to  $\mathbb{R}^n$  is AREA-preserving if

$$m(F(A)) = m(A)$$

for every subregion  $A$  of  $\mathbb{R}^n$ , where  $m(A)$  is the  $n$ -D MEASURE of  $A$ . A linear transformation is AREA-preserving if its corresponding DETERMINANT is equal to 1.

see also CONFORMAL MAP, SYMPLECTIC MAP

## Area Principle

The "AREA principle" states that

$$\frac{|A_1P|}{|A_2P|} = \frac{|A_1BC|}{|A_2BC|}. \quad (1)$$

This can also be written in the form

$$\left[ \frac{A_1P}{A_2P} \right] = \left[ \frac{A_1BC}{A_2BC} \right], \quad (2)$$

where

$$\left[ \frac{AB}{CD} \right] \quad (3)$$

is the ratio of the lengths  $[A, B]$  and  $[C, D]$  for  $AB \parallel CD$  with a PLUS or MINUS SIGN depending on if these segments have the same or opposite directions, and

$$\left[ \frac{ABC}{DEFG} \right] \quad (4)$$

is the RATIO of signed AREAS of the TRIANGLES. Grünbaum and Shepard show that CEVA'S THEOREM, HOEHN'S THEOREM, and MENELAUS' THEOREM are the consequences of this result.

see also CEVA'S THEOREM, HOEHN'S THEOREM, MENELAUS' THEOREM, SELF-TRANSVERSALITY THEOREM

## References

Grünbaum, B. and Shepard, G. C. "Ceva, Menelaus, and the Area Principle." *Math. Mag.* **68**, 254–268, 1995.

## Areal Coordinates

TRILINEAR COORDINATES normalized so that

$$t_1 + t_2 + t_3 = 1.$$

When so normalized, they become the AREAS of the TRIANGLES  $PA_1A_2$ ,  $PA_1A_3$ , and  $PA_2A_3$ , where  $P$  is the point whose coordinates have been specified.

## Arf Invariant

A LINK invariant which always has the value 0 or 1. A KNOT has ARF INVARIANT 0 if the KNOT is "pass equivalent" to the UNKNOT and 1 if it is pass equivalent to the TREFOIL KNOT. If  $K_+$ ,  $K_-$ , and  $L$  are projections which are identical outside the region of the crossing diagram, and  $K_+$  and  $K_-$  are KNOTS while  $L$  is a 2-component LINK with a nonintersecting crossing

diagram where the two left and right strands belong to the different LINKS, then

$$a(K_+) = a(K_-) + l(L_1, L_2), \quad (1)$$

where  $l$  is the LINKING NUMBER of  $L_1$  and  $L_2$ . The Arf invariant can be determined from the ALEXANDER POLYNOMIAL or JONES POLYNOMIAL for a KNOT. For  $\Delta_K$  the ALEXANDER POLYNOMIAL of  $K$ , the Arf invariant is given by

$$\Delta_K(-1) \equiv \begin{cases} 1 \pmod{8} & \text{if } \text{Arf}(K) = 0 \\ 5 \pmod{8} & \text{if } \text{Arf}(K) = 1 \end{cases} \quad (2)$$

(Jones 1985). For the JONES POLYNOMIAL  $W_K$  of a KNOT  $K$ ,

$$\text{Arf}(K) = W_K(i) \quad (3)$$

(Jones 1985), where  $i$  is the IMAGINARY NUMBER.

## Argand Diagram

A plot of COMPLEX NUMBERS as points

$$z = x + iy$$

using the  $x$ -AXIS as the REAL axis and  $y$ -AXIS as the IMAGINARY axis. This is also called the COMPLEX PLANE or ARGAND PLANE.

## Argand Plane

see ARGAND DIAGRAM

## Argoh's Conjecture

Let  $B_k$  be the  $k$ th BERNOULLI NUMBER. Then does

$$nB_{n-1} \equiv -1 \pmod{n}$$

IFF  $n$  is PRIME? For example, for  $n = 1, 2, \dots, nB_{n-1} \pmod{n}$  is 0,  $-1$ ,  $-1$ , 0,  $-1$ , 0,  $-1$ , 0,  $-3$ , 0,  $-1$ ,  $\dots$ . There are no counterexamples less than  $n = 5,600$ . Any counterexample to Argoh's conjecture would be a contradiction to GIUGA'S CONJECTURE, and vice versa.

see also BERNOULLI NUMBER, GIUGA'S CONJECTURE

## References

Borwein, D.; Borwein, J. M.; Borwein, P. B.; and Girgensohn, R. "Giuga's Conjecture on Primality." *Amer. Math. Monthly* **103**, 40–50, 1996.

**Argument Addition Relation**

A mathematical relationship relating  $f(x + y)$  to  $f(x)$  and  $f(y)$ .

see also ARGUMENT MULTIPLICATION RELATION, RECURRENCE RELATION, REFLECTION RELATION, TRANSLATION RELATION

**Argument (Complex Number)**

A COMPLEX NUMBER  $z$  may be represented as

$$z \equiv x + iy = |z|e^{i\theta}, \quad (1)$$

where  $|z|$  is called the MODULUS of  $z$ , and  $\theta$  is called the argument

$$\arg(x + iy) \equiv \tan^{-1} \left( \frac{y}{x} \right). \quad (2)$$

Therefore,

$$\begin{aligned} \arg(zw) &= \arg(|z|e^{i\theta_z}|w|e^{i\theta_w}) = \arg(e^{i\theta_z}e^{i\theta_w}) \\ &= \arg[e^{i(\theta_z + \theta_w)}] = \arg(z) + \arg(w). \end{aligned} \quad (3)$$

Extending this procedure gives

$$\arg(z^n) = n \arg(z). \quad (4)$$

The argument of a COMPLEX NUMBER is sometimes called the PHASE.

see also AFFIX, COMPLEX NUMBER, DE MOIVRE'S IDENTITY, EULER FORMULA, MODULUS (COMPLEX NUMBER), PHASE, PHASOR

**References**

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, p. 16, 1972.

**Argument (Elliptic Integral)**

Given an AMPLITUDE  $\phi$  in an ELLIPTIC INTEGRAL, the argument  $u$  is defined by the relation

$$\phi \equiv \operatorname{am} u.$$

see also AMPLITUDE, ELLIPTIC INTEGRAL

**Argument (Function)**

An argument of a FUNCTION  $f(x_1, \dots, x_n)$  is one of the  $n$  parameters on which the function's value depends. For example, the SINE  $\sin x$  is a one-argument function, the BINOMIAL COEFFICIENT  $\binom{n}{m}$  is a two-argument function, and the HYPERGEOMETRIC FUNCTION  ${}_2F_1(a, b; c; z)$  is a four-argument function.

**Argument Multiplication Relation**

A mathematical relationship relating  $f(nx)$  to  $f(x)$  for INTEGER  $n$ .

see also ARGUMENT ADDITION RELATION, RECURRENCE RELATION, REFLECTION RELATION, TRANSLATION RELATION

**Argument Principle**

If  $f(z)$  is MEROMORPHIC in a region  $R$  enclosed by a curve  $\gamma$ , let  $N$  be the number of COMPLEX ROOTS of  $f(z)$  in  $\gamma$ , and  $P$  be the number of POLES in  $\gamma$ , then

$$N - P = \frac{1}{2\pi i} \int_{\gamma} \frac{f'(z) dz}{f(z)}.$$

Defining  $w \equiv f(z)$  and  $\sigma \equiv f(\gamma)$  gives

$$N - P = \frac{1}{2\pi i} \int_{\sigma} \frac{dw}{w}.$$

**Aristotle's Wheel Paradox**

A PARADOX mentioned in the Greek work *Mechanica*, dubiously attributed to Aristotle. Consider the above diagram depicting a wheel consisting of two concentric CIRCLES of different DIAMETERS (a wheel within a wheel). There is a 1:1 correspondence of points on the large CIRCLE with points on the small CIRCLE, so the wheel should travel the same distance regardless of whether it is rolled from left to right on the top straight line or on the bottom one. This seems to imply that the two CIRCUMFERENCES of different sized CIRCLES are equal, which is impossible.

The fallacy lies in the assumption that a 1:1 correspondence of points means that two curves must have the same length. In fact, the CARDINALITIES of points in a LINE SEGMENT of any length (or even an INFINITE LINE, a PLANE, a 3-D SPACE, or an infinite dimensional EUCLIDEAN SPACE) are all the same:  $\aleph_1$  (ALEPH-1), so the points of any of these can be put in a ONE-TO-ONE correspondence with those of any other.

**Arithmetic**

The branch of mathematics dealing with INTEGERS or, more generally, numerical computation. Arithmetical operations include ADDITION, CONGRUENCE calculation, DIVISION, FACTORIZATION, MULTIPLICATION, POWER computation, ROOT extraction, and SUBTRACTION.

The FUNDAMENTAL THEOREM OF ARITHMETIC, also called the UNIQUE FACTORIZATION THEOREM, states that any POSITIVE INTEGER can be represented in exactly one way as a PRODUCT of PRIMES.

The LÖWENHEIMER-SKOLEM THEOREM, which is a fundamental result in MODEL THEORY, establishes the existence of “nonstandard” models of arithmetic.

see also ALGEBRA, CALCULUS, FUNDAMENTAL THEOREM OF ARITHMETIC, GROUP THEORY, HIGHER ARITHMETIC, LINEAR ALGEBRA, LÖWENHEIMER-SKOLEM THEOREM, MODEL THEORY, NUMBER THEORY, TRIGONOMETRY

**Arithmetic-Geometric Mean**

The arithmetic-geometric mean (AGM)  $M(a, b)$  of two numbers  $a$  and  $b$  is defined by starting with  $a_0 \equiv a$  and  $b_0 \equiv b$ , then iterating

$$a_{n+1} = \frac{1}{2}(a_n + b_n) \quad (1)$$

$$b_{n+1} = \sqrt{a_n b_n} \quad (2)$$

until  $a_n = b_n$ .  $a_n$  and  $b_n$  converge towards each other since

$$\begin{aligned} a_{n+1} - b_{n+1} &= \frac{1}{2}(a_n + b_n) - \sqrt{a_n b_n} \\ &= \frac{a_n - 2\sqrt{a_n b_n} + b_n}{2}. \end{aligned} \quad (3)$$

But  $\sqrt{b_n} < \sqrt{a_n}$ , so

$$2b_n < 2\sqrt{a_n b_n}. \quad (4)$$

Now, add  $a_n - b_n - 2\sqrt{a_n b_n}$  to each side

$$a_n + b_n - 2\sqrt{a_n b_n} < a_n - b_n, \quad (5)$$

so

$$a_{n+1} - b_{n+1} < \frac{1}{2}(a_n - b_n). \quad (6)$$

The AGM is very useful in computing the values of complete ELLIPTIC INTEGRALS and can also be used for finding the INVERSE TANGENT. The special value  $1/M(1, \sqrt{2})$  is called GAUSS'S CONSTANT.

The AGM has the properties

$$\lambda M(a, b) = M(\lambda a, \lambda b) \quad (7)$$

$$M(a, b) = M\left(\frac{1}{2}(a + b), \sqrt{ab}\right) \quad (8)$$

$$M(1, \sqrt{1 - x^2}) = M(1 + x, 1 - x) \quad (9)$$

$$M(1, b) = \frac{1 + b}{2} M\left(1, \frac{2\sqrt{b}}{1 + b}\right). \quad (10)$$

The Legendre form is given by

$$M(1, x) = \prod_{n=0}^{\infty} \frac{1}{2}(1 + k_n), \quad (11)$$

where  $k_0 \equiv x$  and

$$k_{n+1} \equiv \frac{2\sqrt{k_n}}{1 + k_n}. \quad (12)$$

Solutions to the differential equation

$$(x^3 - x) \frac{d^2 y}{dx^2} + (3x^2 - 1) \frac{dy}{dx} + xy = 0 \quad (13)$$

are given by  $[M(1 + x, 1 - x)]^{-1}$  and  $[M(1, x)]^{-1}$ .

A generalization of the ARITHMETIC-GEOMETRIC MEAN is

$$I_p(a, b) = \int_0^{\infty} \frac{x^{p-2} dx}{(x^p + a^p)^{1/p} (x^p + b^p)^{(p-1)/p}}, \quad (14)$$

which is related to solutions of the differential equation

$$x(1 - x^p)Y'' + [1 - (p+1)x^p]Y' - (p-1)x^{p-1}Y = 0. \quad (15)$$

When  $p = 2$  or  $p = 3$ , there is a modular transformation for the solutions of (15) that are bounded as  $x \rightarrow 0$ . Letting  $J_p(x)$  be one of these solutions, the transformation takes the form

$$J_p(\lambda) = \mu J_p(x), \quad (16)$$

where

$$\lambda = \frac{1 - u}{1 + (p-1)u} \quad (17)$$

$$\mu = \frac{1 + (p-1)u}{p} \quad (18)$$

and

$$x^p + u^p = 1. \quad (19)$$

The case  $p = 2$  gives the ARITHMETIC-GEOMETRIC MEAN, and  $p = 3$  gives a cubic relative discussed by Borwein and Borwein (1990, 1991) and Borwein (1996) in which, for  $a, b > 0$  and  $I(a, b)$  defined by

$$I(a, b) = \int_0^{\infty} \frac{t dt}{[(a^3 + t^3)(b^3 + t^3)^2]^{1/3}}, \quad (20)$$

$$I(a, b) = I\left(\frac{a+2b}{3}, \left[\frac{b}{3}(a^2 + ab + b^2)\right]\right). \quad (21)$$

For iteration with  $a_0 = a$  and  $b_0 = b$  and

$$a_{n+1} = \frac{a_n + 2b_n}{3} \quad (22)$$

$$b_{n+1} = \frac{b_n}{3}(a_n^2 + a_nb_n + b_n^2), \quad (23)$$

$$\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} b_n = \frac{I(1, 1)}{I(a, b)}. \quad (24)$$

Modular transformations are known when  $p = 4$  and  $p = 6$ , but they do not give identities for  $p = 6$  (Borwein 1996).

### Arithmetic-Harmonic Mean

Let

$$a_{n+1} = \frac{1}{2}(a_n + b_n) \quad (1)$$

$$b_{n+1} = \frac{2a_nb_n}{a_n + b_n}. \quad (2)$$

Then

$$A(a_0, b_0) = \lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} b_n = \sqrt{a_0 b_0}, \quad (3)$$

which is just the GEOMETRIC MEAN.

### Arithmetic-Logarithmic-Geometric Mean Inequality

$$\frac{a+b}{2} > \frac{b-a}{\ln b - \ln a} > \sqrt{ab}.$$

### Arithmetic Mean

For a CONTINUOUS DISTRIBUTION function, the arithmetic mean of the population, denoted  $\mu$ ,  $\bar{x}$ ,  $\langle x \rangle$ , or  $A(x)$ , is given by

$$\mu = \langle f(x) \rangle \equiv \int_{-\infty}^{\infty} P(x)f(x) dx, \quad (1)$$

where  $\langle x \rangle$  is the EXPECTATION VALUE. For a DISCRETE DISTRIBUTION,

$$\mu = \langle f(x) \rangle \equiv \frac{\sum_{n=0}^N P(x_n)f(x_n)}{\sum_{n=0}^N P(x_n)} = \sum_{n=0}^N P(x_n)f(x_n). \quad (2)$$

The population mean satisfies

$$\langle f(x) + g(x) \rangle = \langle f(x) \rangle + \langle g(x) \rangle \quad (3)$$

$$\langle cf(x) \rangle = c \langle f(x) \rangle, \quad (4)$$

and

$$\langle f(x)g(y) \rangle = \langle f(x) \rangle \langle g(y) \rangle \quad (5)$$

if  $x$  and  $y$  are INDEPENDENT STATISTICS. The "sample mean," which is the mean estimated from a statistical sample, is an UNBIASED ESTIMATOR for the population mean.

For small samples, the mean is more efficient than the MEDIAN and approximately  $\pi/2$  less (Kenney and Keeping 1962, p. 211). A general expression which often holds approximately is

$$\text{mean} - \text{mode} \approx 3(\text{mean} - \text{median}). \quad (6)$$

Given a set of samples  $\{x_i\}$ , the arithmetic mean is

$$A(x) = \bar{x} = \mu \equiv \langle x \rangle = \frac{1}{N} \sum_{i=1}^N x_i. \quad (7)$$

Hoehn and Niven (1985) show that

$$A(a_1 + c, a_2 + c, \dots, a_n + c) = c + A(a_1, a_2, \dots, a_n) \quad (8)$$

for any POSITIVE constant  $c$ . The arithmetic mean satisfies

$$A \geq G \geq H, \quad (9)$$

where  $G$  is the GEOMETRIC MEAN and  $H$  is the HARMONIC MEAN (Hardy *et al.* 1952; Mitrinović 1970; Beckenbach and Bellman 1983; Bullen *et al.* 1988; Mitrinović *et al.* 1993; Alzer 1996). This can be shown as follows. For  $a, b > 0$ ,

$$\left(\frac{1}{\sqrt{a}} - \frac{1}{\sqrt{b}}\right)^2 \geq 0 \quad (10)$$

$$\frac{1}{a} - \frac{2}{\sqrt{ab}} + \frac{1}{b} \geq 0 \quad (11)$$

$$\frac{1}{a} + \frac{1}{b} \geq \frac{2}{\sqrt{ab}} \quad (12)$$

$$\frac{2}{\frac{1}{a} + \frac{1}{b}} \geq \sqrt{ab} \quad (13)$$

$$H \geq G, \quad (14)$$

with equality IFF  $b = a$ . To show the second part of the inequality,

$$(\sqrt{a} - \sqrt{b})^2 = a - 2\sqrt{ab} + b \geq 0 \quad (15)$$

$$\frac{a+b}{2} \geq \sqrt{ab} \quad (16)$$

$$A \geq H, \quad (17)$$

with equality IFF  $a = b$ . Combining (14) and (17) then gives (9).

Given  $n$  independent random GAUSSIAN DISTRIBUTED variates  $x_i$ , each with population mean  $\mu_i = \mu$  and VARIANCE  $\sigma_i^2 = \sigma^2$ ,

$$\bar{x} \equiv \frac{1}{N} \sum_{i=1}^N x_i \quad (18)$$

$$\begin{aligned} \langle \bar{x} \rangle &= \frac{1}{N} \left\langle \sum_{i=1}^N x_i \right\rangle = \frac{1}{N} \sum_{i=1}^N \langle x_i \rangle \\ &= \frac{1}{N} \sum_{i=1}^N \mu = \frac{1}{N} (N\mu) = \mu, \end{aligned} \quad (19)$$

so the sample mean is an UNBIASED ESTIMATOR of population mean. However, the distribution of  $\bar{x}$  depends on the sample size. For large samples,  $\bar{x}$  is approximately NORMAL. For small samples, STUDENT'S  $t$ -DISTRIBUTION should be used.

The VARIANCE of the population mean is independent of the distribution.

$$\begin{aligned} \text{var}(\bar{x}) &= \text{var}\left(\frac{1}{n} \sum_{i=1}^N x_i\right) = \frac{1}{N^2} \text{var}\left(\sum_{i=1}^N x_i\right) \\ &= \frac{1}{N^2} \sum_{i=1}^n \text{var}(x_i) = \left(\frac{1}{N^2}\right) \sum_{i=1}^N \sigma^2 = \frac{\sigma^2}{N}. \end{aligned} \quad (20)$$

From  $k$ -STATISTICS for a GAUSSIAN DISTRIBUTION, the UNBIASED ESTIMATOR for the VARIANCE is given by

$$\sigma^2 = \frac{N}{N-1} s^2, \quad (21)$$

where

$$s \equiv \frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^2, \quad (22)$$

so

$$\text{var}(\bar{x}) = \frac{s^2}{N-1}. \quad (23)$$

The SQUARE ROOT of this,

$$\sigma_x = \frac{s}{\sqrt{N-1}}, \quad (24)$$

is called the STANDARD ERROR.

$$\text{var}(\bar{x}) \equiv \langle \bar{x}^2 \rangle - \langle \bar{x} \rangle^2, \quad (25)$$

so

$$\langle \bar{x}^2 \rangle = \text{var}(\bar{x}) + \langle \bar{x} \rangle^2 = \frac{\sigma^2}{N} + \mu^2. \quad (26)$$

### Arithmetic Progression

see ARITHMETIC SERIES

## Arithmetic Sequence

A SEQUENCE of  $n$  numbers  $\{d_0 + kd\}_{k=0}^{n-1}$  such that the differences between successive terms is a constant  $d$ .

see also ARITHMETIC SERIES, SEQUENCE

## Arithmetic Series

An arithmetic series is the SUM of a SEQUENCE  $\{a_k\}$ ,  $k = 1, 2, \dots$ , in which each term is computed from the previous one by adding (or subtracting) a constant. Therefore, for  $k > 1$ ,

$$a_k = a_{k-1} + d = a_{k-2} + 2d = \dots = a_1 + d(k-1). \quad (1)$$

The sum of the sequence of the first  $n$  terms is then given by

$$\begin{aligned} S_n &= \sum_{k=1}^n a_k = \sum_{k=1}^n [a_1 + (k-1)d] \\ &= na_1 + d \sum_{k=1}^n (k-1) = na_1 + d \sum_{k=2}^n (k-1) \\ &= na_1 + d \sum_{k=1}^{n-1} k \end{aligned} \quad (2)$$

Using the SUM identity

$$\sum_{k=1}^n k = \frac{1}{2}n(n+1) \quad (3)$$

then gives

$$S_n = na_1 + \frac{1}{2}d(n-1) = \frac{1}{2}n[2a_1 + d(n-1)]. \quad (4)$$

Note, however, that

$$a_1 + a_n = a_1 + [a_1 + d(n-1)] = 2a_1 + d(n-1), \quad (5)$$

so

$$S_n = \frac{1}{2}n(a_1 + a_n), \quad (6)$$

or  $n$  times the AVERAGE of the first and last terms! This is the trick Gauss used as a schoolboy to solve the problem of summing the INTEGERS from 1 to 100 given as busy-work by his teacher. While his classmates toiled away doing the ADDITION longhand, Gauss wrote a single number, the correct answer

$$\frac{1}{2}(100)(1+100) = 50 \cdot 101 = 5050 \quad (7)$$

on his slate. When the answers were examined, Gauss's proved to be the only correct one.

## Armstrong Number

The  $n$ -digit numbers equal to sum of  $n$ th powers of their digits (a finite sequence), also called PLUS PERFECT NUMBERS. They first few are given by 1, 2, 3, 4, 5, 6, 7, 8, 9, 153, 370, 371, 407, 1634, 8208, 9474, 54748, ... (Sloane's A005188).

see also NARCISSISTIC NUMBER

## References

Sloane, N. J. A. Sequence A005188/M0488 in "An On-Line Version of the Encyclopedia of Integer Sequences."

## Arnold's Cat Map

The best known example of an ANOSOV DIFFEOMORPHISM. It is given by the TRANSFORMATION

$$\begin{bmatrix} x_{n+1} \\ y_{n+1} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix}, \quad (1)$$

where  $x_{n+1}$  and  $y_{n+1}$  are computed mod 1. The Arnold cat mapping is non-Hamiltonian, nonanalytic, and mixing. However, it is AREA-PRESERVING since the DETERMINANT is 1. The LYAPUNOV CHARACTERISTIC EXPONENTS are given by

$$\begin{vmatrix} 1-\sigma & 1 \\ 1 & 2-\sigma \end{vmatrix} = \sigma^2 - 3\sigma + 1 = 0, \quad (2)$$

so

$$\sigma_{\pm} = \frac{1}{2}(3 \pm \sqrt{5}). \quad (3)$$

The EIGENVECTORS are found by plugging  $\sigma_{\pm}$  into the MATRIX EQUATION

$$\begin{bmatrix} 1-\sigma_{\pm} & 1 \\ 1 & 2-\sigma_{\pm} \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \quad (4)$$

For  $\sigma_+$ , the solution is

$$y = \frac{1}{2}(1 + \sqrt{5})x \equiv \phi x, \quad (5)$$

where  $\phi$  is the GOLDEN RATIO, so the unstable (normalized) EIGENVECTOR is

$$\xi_+ = \frac{1}{10}\sqrt{50-10\sqrt{5}} \begin{bmatrix} 1 \\ \frac{1}{2}(1+\sqrt{5}) \end{bmatrix}. \quad (6)$$

Similarly, for  $\sigma_-$ , the solution is

$$y = -\frac{1}{2}(\sqrt{5}-1)x \equiv \phi^{-1}x, \quad (7)$$

so the stable (normalized) EIGENVECTOR is

$$\xi_- = \frac{1}{10}\sqrt{50+10\sqrt{5}} \begin{bmatrix} 1 \\ \frac{1}{2}(1-\sqrt{5}) \end{bmatrix}. \quad (8)$$

see also ANOSOV MAP

### Arnold Diffusion

The nonconservation of ADIABATIC INVARIANTS which arises in systems with three or more DEGREES OF FREEDOM.

### Arnold Tongue

Consider the CIRCLE MAP. If  $K$  is NONZERO, then the motion is periodic in some FINITE region surrounding each rational  $\Omega$ . This execution of periodic motion in response to an irrational forcing is known as MODE LOCKING. If a plot is made of  $K$  versus  $\Omega$  with the regions of periodic MODE-LOCKED parameter space plotted around rational  $\Omega$  values (the WINDING NUMBERS), then the regions are seen to widen upward from 0 at  $K = 0$  to some FINITE width at  $K = 1$ . The region surrounding each RATIONAL NUMBER is known as an ARNOLD TONGUE.

At  $K = 0$ , the Arnold tongues are an isolated set of MEASURE zero. At  $K = 1$ , they form a general CANTOR SET of dimension  $d \approx 0.8700$ . In general, an Arnold tongue is defined as a resonance zone emanating out from RATIONAL NUMBERS in a two-dimensional parameter space of variables.

see also CIRCLE MAP

### Aronhold Process

The process used to generate an expression for a covariant in the first degree of any one of the equivalent sets of COEFFICIENTS for a curve.

### Arrangement

In general, an arrangement of objects is simply a grouping of them. The number of "arrangements" of  $n$  items is given either by a COMBINATION (order is ignored) or PERMUTATION (order is significant).

The division of SPACE into cells by a collection of HYPERPLANES is also called an arrangement.

see also COMBINATION, CUTTING, HYPERPLANE, ORDERING, PERMUTATION

### Arrangement Number

see PERMUTATION

### Array

An array is a "list of lists" with the length of each level of list the same. The size (sometimes called the "shape") of a  $d$ -dimensional array is then indicated as  $\underbrace{m \times n \times \cdots \times p}_d$ . The most common type of array en-

countered is the 2-D  $m \times n$  rectangular array having  $m$  columns and  $n$  rows. If  $m = n$ , a square array results. Sometimes, the order of the elements in an array is significant (as in a MATRIX), whereas at other times, arrays which are equivalent modulo reflections (and rotations, in the case of a square array) are considered identical (as in a MAGIC SQUARE or PRIME ARRAY).

In order to exhaustively list the number of distinct arrays of a given shape with each element being one of  $k$  possible choices, the naive algorithm of running through each case and checking to see whether it's equivalent to an earlier one is already just about as efficient as can be. The running time must be at least the number of answers, and this is so close to  $k^{mn \cdots p}$  that the difference isn't significant.

However, finding the number of possible arrays of a given shape is much easier, and an exact formula can be obtained using the POLYA ENUMERATION THEOREM. For the simple case of an  $m \times n$  array, even this proves unnecessary since there are only a few possible symmetry types, allowing the possibilities to be counted explicitly. For example, consider the case of  $m$  and  $n$  EVEN and distinct, so only reflections need be included. To take a specific case, let  $m = 6$  and  $n = 4$  so the array looks like

$a$	$b$	$c$		$d$	$e$	$f$
$g$	$h$	$i$		$j$	$k$	$l$
$-$	$-$	$-$	+	$-$	$-$	$-$
$m$	$n$	$o$		$p$	$q$	$r$
$s$	$t$	$u$		$v$	$w$	$x$

where each  $a, b, \dots, x$  can take a value from 1 to  $k$ . The total number of possible arrangements is  $k^{24}$  ( $k^{mn}$  in general). The number of arrangements which are equivalent to their left-right mirror images is  $k^{12}$  (in general,  $k^{mn/2}$ ), as is the number equal to their up-down mirror images, or their rotations through  $180^\circ$ . There are also  $k^6$  arrangements (in general,  $k^{mn/4}$ ) with full symmetry.

In general, it is therefore true that

$$\begin{cases} k^{mn/4} & \text{with full symmetry} \\ k^{mn/2} - k^{mn/4} & \text{with only left-right reflection} \\ k^{mn/2} - k^{mn/4} & \text{with only up-down reflection} \\ k^{mn/2} - k^{mn/4} & \text{with only } 180^\circ \text{ rotation,} \end{cases}$$

so there are

$$k^{mn} - 3k^{mn/2} + 2k^{mn/4}$$

arrangements with no symmetry. Now dividing by the number of images of each type, the result, for  $m \neq n$  with  $m, n$  EVEN, is

$$\begin{aligned} N(m, n, k) &= \frac{1}{4}k^{mn} + \left(\frac{1}{2}\right)(3)(k^{mn/2} - k^{mn/4}) \\ &\quad + \frac{1}{4}(k^{mn} - 3k^{mn/2} + 2k^{mn/4}) \\ &= \frac{1}{4}k^{mn} + \frac{3}{4}k^{mn/2} + \frac{1}{2}k^{mn/4}. \end{aligned}$$

The number is therefore of order  $\mathcal{O}(k^{mn}/4)$ , with "correction" terms of much smaller order.

see also ANTIMAGIC SQUARE, EULER SQUARE, KIRKMAN'S SCHOOLGIRL PROBLEM, LATIN RECTANGLE, LATIN SQUARE, MAGIC SQUARE, MATRIX, MRS. PERKINS' QUILT, MULTIPLICATION TABLE, ORTHOGONAL ARRAY, PERFECT SQUARE, PRIME ARRAY, QUOTIENT-DIFFERENCE TABLE, ROOM SQUARE, STOLARSKY ARRAY, TRUTH TABLE, WYTHOFF ARRAY

### Arrow Notation

A NOTATION invented by Knuth (1976) to represent LARGE NUMBERS in which evaluation proceeds from the right (Conway and Guy 1996, p. 60).

$$\begin{array}{ccc} m \uparrow n & \underbrace{m \cdot m \cdots m}_n \\ m \uparrow \uparrow n & \underbrace{m \uparrow m \uparrow \cdots \uparrow m}_n \\ m \uparrow \uparrow \uparrow n & \underbrace{m \uparrow \uparrow m \uparrow \uparrow \cdots \uparrow \uparrow m}_n \end{array}$$

For example,

$$m \uparrow n = m^n \quad (1)$$

$$m \uparrow \uparrow n = \underbrace{m \uparrow \cdots \uparrow m}_n = \underbrace{m^{m \cdots m}}_n$$

$$m \uparrow \uparrow 2 = \underbrace{m \uparrow m}_2 = m \uparrow m = m^m \quad (2)$$

$$\begin{aligned} m \uparrow \uparrow 3 &= \underbrace{m \uparrow m \uparrow m}_3 = m \uparrow (m \uparrow m) \\ &= m \uparrow m^m = m^{m^m} \end{aligned} \quad (3)$$

$$m \uparrow \uparrow \uparrow 2 = \underbrace{m \uparrow \uparrow m}_2 = m \uparrow \uparrow m = \underbrace{m^{m \cdots m}}_m \quad (4)$$

$$\begin{aligned} m \uparrow \uparrow \uparrow 3 &= \underbrace{m \uparrow \uparrow m \uparrow \uparrow m}_3 = m \uparrow \uparrow \underbrace{m^{m \cdots m}}_m \\ &= \underbrace{m \uparrow \cdots \uparrow m}_m = \underbrace{m^{m \cdots m}}_m \end{aligned} \quad (5)$$

$m \uparrow \uparrow n$  is sometimes called a POWER TOWER. The values  $\underbrace{n \uparrow \cdots \uparrow n}_n$  are called ACKERMANN NUMBERS.

see also ACKERMANN NUMBER, CHAINED ARROW NOTATION, DOWN ARROW NOTATION, LARGE NUMBER, POWER TOWER, STEINHAUS-MOSER NOTATION

### Art Gallery Theorem

Also called CHVÁTAL'S ART GALLERY THEOREM. If the walls of an art gallery are made up of  $n$  straight LINES SEGMENTS, then the entire gallery can always be supervised by  $\lfloor n/3 \rfloor$  watchmen placed in corners, where  $\lfloor x \rfloor$  is the FLOOR FUNCTION. This theorem was proved by V. Chvátal in 1973. It is conjectured that an art gallery with  $n$  walls and  $h$  HOLES requires  $\lfloor (n+h)/3 \rfloor$  watchmen.

### Artin Braid Group

see BRAID GROUP

**Artin's Conjecture**

There are at least two statements which go by the name of Artin's conjecture. The first is the RIEMANN HYPOTHESIS. The second states that every INTEGER not equal to  $-1$  or a SQUARE NUMBER is a primitive root modulo  $p$  for infinitely many  $p$  and proposes a density for the set of such  $p$  which are always rational multiples of a constant known as ARTIN'S CONSTANT. There is an analogous theorem for functions instead of numbers which has been proved by Billharz (Shanks 1993, p. 147).

see also ARTIN'S CONSTANT, RIEMANN HYPOTHESIS

**References**

Shanks, D. *Solved and Unsolved Problems in Number Theory*, 4th ed. New York: Chelsea, pp. 31, 80–83, and 147, 1993.

**Artin's Constant**

If  $n \neq -1$  and  $n$  is not a PERFECT SQUARE, then Artin conjectured that the SET  $S(n)$  of all PRIMES for which  $n$  is a PRIMITIVE ROOT is infinite. Under the assumption of the EXTENDED RIEMANN HYPOTHESIS, Artin's conjecture was solved in 1967 by C. Hooley. If, in addition,  $n$  is not an  $r$ th POWER for any  $r > 1$ , then Artin conjectured that the density of  $S(n)$  relative to the PRIMES is  $C_{\text{Artin}}$  (independent of the choice of  $n$ ), where

$$C_{\text{Artin}} = \prod_{q \text{ prime}} \left[ 1 - \frac{1}{q(q-1)} \right] = 0.3739558136 \dots,$$

and the PRODUCT is over PRIMES. The significance of this constant is more easily seen by describing it as the fraction of PRIMES  $p$  for which  $1/p$  has a maximal DECIMAL EXPANSION (Conway and Guy 1996).

**Artin L-Function**

An Artin  $L$ -function over the RATIONALS  $\mathbb{Q}$  encodes in a GENERATING FUNCTION information about how an irreducible monic POLYNOMIAL over  $\mathbb{Z}$  factors when reduced modulo each PRIME. For the POLYNOMIAL  $x^2 + 1$ , the Artin  $L$ -function is

$$L(s, \mathbb{Q}(i)/\mathbb{Q}, \text{sgn}) = \prod_{p \text{ odd prime}} \frac{1}{1 - \left(\frac{-1}{p}\right) p^{-s}},$$

where  $(-1/p)$  is a LEGENDRE SYMBOL, which is equivalent to the EULER  $L$ -FUNCTION. The definition over arbitrary POLYNOMIALS generalizes the above expression.

**Artistic Series**

A SERIES is called artistic if every three consecutive terms have a common three-way ratio

$$P[a_i, a_{i+1}, a_{i+2}] = \frac{(a_i + a_{i+1} + a_{i+2})a_{i+1}}{a_i a_{i+2}}.$$

A SERIES is also artistic IFF its BIAS is a constant. A GEOMETRIC SERIES with RATIO  $r > 0$  is an artistic series with

$$P = \frac{1}{r} + 1 + r \geq 3.$$

see also BIAS (SERIES), GEOMETRIC SERIES, MELODIC SERIES

### ASA Theorem

Specifying two adjacent ANGLES  $A$  and  $B$  and the side between them  $c$  uniquely determines a TRIANGLE with AREA

$$K = \frac{c^2}{2(\cot A + \cot B)}. \quad (1)$$

The angle  $C$  is given in terms of  $A$  and  $B$  by

$$C = \pi - A - B, \quad (2)$$

and the sides  $a$  and  $b$  can be determined by using the LAW OF SINES

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} \quad (3)$$

to obtain

$$a = \frac{\sin A}{\sin(\pi - A - B)} c \quad (4)$$

$$b = \frac{\sin B}{\sin(\pi - A - B)} c. \quad (5)$$

see also AAA THEOREM, AAS THEOREM, ASS THEOREM, SAS THEOREM, SSS THEOREM, TRIANGLE

### Aschbacher's Component Theorem

Suppose that  $E(G)$  (the commuting product of all components of  $G$ ) is SIMPLE and  $G$  contains a SEMISIMPLE INVOLUTION. Then there is some SEMISIMPLE INVOLUTION  $x$  such that  $C_G(x)$  has a NORMAL SUBGROUP  $K$  which is either QUASISIMPLE or ISOMORPHIC to  $O^+(4, q)'$  and such that  $Q = C_G(K)$  is TIGHTLY EMBEDDED.

see also INVOLUTION (GROUP), ISOMORPHIC GROUPS, NORMAL SUBGROUP, QUASISIMPLE GROUP, SIMPLE GROUP, TIGHTLY EMBEDDED

### ASS Theorem

Specifying two adjacent side lengths  $a$  and  $b$  of a TRIANGLE (taking  $a > b$ ) and one ACUTE ANGLE  $A$  opposite  $a$  does not, in general, uniquely determine a triangle. If  $\sin A < a/c$ , there are two possible TRIANGLES satisfying the given conditions. If  $\sin A = a/c$ , there is one possible TRIANGLE. If  $\sin A > a/c$ , there are no possible TRIANGLES. Remember: don't try to prove congruence with the ASS theorem or you will make an ASS out of yourself.

see also AAA THEOREM, AAS THEOREM, SAS THEOREM, SSS THEOREM, TRIANGLE

### Associative

In simple terms, let  $x$ ,  $y$ , and  $z$  be members of an ALGEBRA. Then the ALGEBRA is said to be associative if

$$x \cdot (y \cdot z) = (x \cdot y) \cdot z, \quad (1)$$

where  $\cdot$  denotes MULTIPLICATION. More formally, let  $A$  denote an  $\mathbb{R}$ -algebra, so that  $A$  is a VECTOR SPACE over  $\mathbb{R}$  and

$$A \times A \rightarrow A \quad (2)$$

$$(x, y) \mapsto x \cdot y. \quad (3)$$

Then  $A$  is said to be  $m$ -associative if there exists an  $m$ -D SUBSPACE  $S$  of  $A$  such that

$$(y \cdot x) \cdot z = y \cdot (x \cdot z) \quad (4)$$

for all  $y, z \in A$  and  $x \in S$ . Here, VECTOR MULTIPLICATION  $x \cdot y$  is assumed to be BILINEAR. An  $n$ -D  $n$ -associative ALGEBRA is simply said to be "associative." see also COMMUTATIVE, DISTRIBUTIVE

**Astroid**

A 4-cusped HYPOCYCLOID which is sometimes also called a TETRACUSPID, CUBOCYCLOID, or PARACYCLE. The parametric equations of the astroid can be obtained by plugging in  $n \equiv a/b = 4$  or  $4/3$  into the equations for a general HYPOCYCLOID, giving

$$x = 3b \cos \phi + b \cos(3\phi) = 4b \cos^3 \phi = a \cos^3 \phi \quad (1)$$

$$y = 3b \sin \phi - b \sin(3\phi) = 4b \sin^3 \phi = a \sin^3 \phi. \quad (2)$$

In CARTESIAN COORDINATES,

$$x^{2/3} + y^{2/3} = a^{2/3}. \quad (3)$$

In PEDAL COORDINATES with the PEDAL POINT at the center, the equation is

$$r^2 + 3p^2 = a^2. \quad (4)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = \frac{3}{2} \int_0^t |\sin(2t')| dt' = \frac{3}{2} \sin^2 t \quad (5)$$

$$\kappa(t) = -\frac{2}{3} \csc(2t) \quad (6)$$

$$\phi(t) = -t. \quad (7)$$

As usual, care must be taken in the evaluation of  $s(t)$  for  $t > \pi/2$ . Since (5) comes from an integral involving the ABSOLUTE VALUE of a function, it must be monotonic increasing. Each QUADRANT can be treated correctly by defining

$$n = \left\lfloor \frac{2t}{\pi} \right\rfloor + 1, \quad (8)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, giving the formula

$$s(t) = (-1)^{1+[n \pmod{2}]} \frac{3}{2} \sin^2 t + 3 \left\lfloor \frac{1}{2} n \right\rfloor. \quad (9)$$

The overall ARC LENGTH of the astroid can be computed from the general HYPOCYCLOID formula

$$s_n = \frac{8a(n-1)}{n} \quad (10)$$

with  $n = 4$ ,

$$s_4 = 6a. \quad (11)$$

The AREA is given by

$$A_n = \frac{(n-1)(n-2)}{n^2} \pi a^2 \quad (12)$$

with  $n = 4$ ,

$$A_4 = \frac{3}{8} \pi a^2. \quad (13)$$

The EVOLUTE of an ELLIPSE is a stretched HYPOCYCLOID. The gradient of the TANGENT  $T$  from the point with parameter  $p$  is  $-\tan p$ . The equation of this TANGENT  $T$  is

$$x \sin p + y \cos p = \frac{1}{2} a \sin(2p) \quad (14)$$

(MacTutor Archive). Let  $T$  cut the  $x$ -AXIS and the  $y$ -AXIS at  $X$  and  $Y$ , respectively. Then the length  $XY$  is a constant and is equal to  $a$ .

The astroid can also be formed as the ENVELOPE produced when a LINE SEGMENT is moved with each end on one of a pair of PERPENDICULAR axes (e.g., it is the curve enveloped by a ladder sliding against a wall or a garage door with the top corner moving along a vertical track; left figure above). The astroid is therefore a GLISSETTE. To see this, note that for a ladder of length  $L$ , the points of contact with the wall and floor are  $(x_0, 0)$  and  $(0, \sqrt{L^2 - x_0^2})$ , respectively. The equation of the LINE made by the ladder with its foot at  $(x_0, 0)$  is therefore

$$y - 0 = \frac{\sqrt{L^2 - x_0^2}}{-x_0} (x - x_0) \quad (15)$$

which can be written

$$U(x, y, x_0) = y + \frac{\sqrt{L^2 - x_0^2}}{x_0} (x - x_0). \quad (16)$$

The equation of the ENVELOPE is given by the simultaneous solution of

$$\begin{cases} U(x, y, x_0) = y + \frac{\sqrt{L^2 - x_0^2}}{x_0} (x - x_0) = 0 \\ \frac{\partial U}{\partial x_0} = \frac{x_0^2 - Lx^2}{x_0^2 \sqrt{L^2 - x_0^2}} = 0, \end{cases} \quad (17)$$

which is

$$x = \frac{x_0^3}{L^2} \quad (18)$$

$$y = \frac{(L^2 - x_0^2)^{3/2}}{L^2}. \quad (19)$$

Noting that

$$x^{2/3} = \frac{x_0^2}{L^{4/3}} \quad (20)$$

$$y^{2/3} = \frac{L^2 - x_0^2}{L^{4/3}} \quad (21)$$

allows this to be written implicitly as

$$x^{2/3} + y^{2/3} = L^{2/3}, \quad (22)$$

the equation of the astroid, as promised.

The related problem obtained by having the “garage door” of length  $L$  with an “extension” of length  $\Delta L$  move up and down a slotted track also gives a surprising answer. In this case, the position of the “extended” end for the foot of the door at horizontal position  $x_0$  and ANGLE  $\theta$  is given by

$$x = -\Delta L \cos \theta \quad (23)$$

$$y = \sqrt{L^2 - x_0^2} + \Delta L \sin \theta. \quad (24)$$

Using

$$x_0 = L \cos \theta \quad (25)$$

then gives

$$x = -\frac{\Delta L}{L} x_0 \quad (26)$$

$$y = \sqrt{L^2 - x_0^2} \left( 1 + \frac{\Delta L}{L} \right). \quad (27)$$

Solving (26) for  $x_0$ , plugging into (27) and squaring then gives

$$y^2 = L^2 - \frac{L^2 x^2}{(\Delta L)^2} \left( 1 + \frac{\Delta L}{L} \right)^2. \quad (28)$$

Rearranging produces the equation

$$\frac{x^2}{(\Delta L)^2} + \frac{y^2}{(L + \Delta L)^2} = 1, \quad (29)$$

the equation of a (QUADRANT of an) ELLIPSE with SEMIMAJOR and SEMINOR AXES of lengths  $\Delta L$  and  $L + \Delta L$ .

The astroid is also the ENVELOPE of the family of ELLIPSES

$$\frac{x^2}{c^2} + \frac{y^2}{(1-c)^2} - 1 = 0, \quad (30)$$

illustrated above.

Nordstrand, T. “Astroidal Ellipsoid.” <http://www.uib.no/people/nfytn/asttxt.htm>.

**Asymptosy**

ASYMPTOTIC behavior. A useful yet endangered word, found rarely outside the captivity of the *Oxford English Dictionary*.

see also ASYMPTOTE, ASYMPTOTIC

**Asymptote**

A curve approaching a given curve arbitrarily closely, as illustrated in the above diagram.

see also ASYMPTOSY, ASYMPTOTE, ASYMPTOTIC CURVE

**References**

Giblin, P. J. “What is an Asymptote?” *Math. Gaz.* **56**, 274–284, 1972.

**Asymptotic**

Approaching a value or curve arbitrarily closely (i.e., as some sort of LIMIT is taken). A CURVE  $A$  which is asymptotic to given CURVE  $C$  is called the ASYMPTOTE of  $C$ .

see also ASYMPTOSY, ASYMPTOTE, ASYMPTOTIC CURVE, ASYMPTOTIC DIRECTION, ASYMPTOTIC SERIES, LIMIT

**Asymptotic Curve**

Given a REGULAR SURFACE  $M$ , an asymptotic curve is formally defined as a curve  $\mathbf{x}(t)$  on  $M$  such that the NORMAL CURVATURE is 0 in the direction  $\mathbf{x}'(t)$  for all  $t$  in the domain of  $\mathbf{x}$ . The differential equation for the parametric representation of an asymptotic curve is

$$eu'^2 + 2fu'v' + gv'^2 = 0, \quad (1)$$

where  $e$ ,  $f$ , and  $g$  are second FUNDAMENTAL FORMS. The differential equation for asymptotic curves on a MONGE PATCH  $(u, v, h(u, v))$  is

$$h_{uu}u'^2 + 2h_{uv}u'v' + h_{vv}v'^2 = 0, \quad (2)$$

and on a polar patch  $(r \cos \theta, r \sin \theta, h(r))$  is

$$h''(r)r'^2 + h'(r)r\theta'^2 = 0. \quad (3)$$

The images below show asymptotic curves for the ELLIPTIC HELICOID, FUNNEL, HYPERBOLIC PARABOLOID, and MONKEY SADDLE.

### Asymptotic Direction

An asymptotic direction at a point  $\mathbf{p}$  of a REGULAR SURFACE  $M \in \mathbb{R}^3$  is a direction in which the NORMAL CURVATURE of  $M$  vanishes.

1. There are no asymptotic directions at an ELLIPTIC POINT.
2. There are exactly two asymptotic directions at a HYPERBOLIC POINT.
3. There is exactly one asymptotic direction at a PARABOLIC POINT.
4. Every direction is asymptotic at a PLANAR POINT.

see also ASYMPTOTIC CURVE

### References

Gray, A. *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 270 and 320, 1993.

### Asymptotic Notation

Let  $n$  be a integer variable which tends to infinity and let  $x$  be a continuous variable tending to some limit. Also, let  $\phi(n)$  or  $\phi(x)$  be a positive function and  $f(n)$  or  $f(x)$  any function. Then Hardy and Wright (1979) define

1.  $f = \mathcal{O}(\phi)$  to mean that  $|f| < A\phi$  for some constant  $A$  and all values of  $n$  and  $x$ ,
2.  $f = o(\phi)$  to mean that  $f/\phi \rightarrow 0$ ,
3.  $f \sim \phi$  to mean that  $f/\phi \rightarrow 1$ ,
4.  $f \prec \phi$  to mean the same as  $f = o(\phi)$ ,
5.  $f \succ \phi$  to mean  $f/\phi \rightarrow \infty$ , and
6.  $f \asymp \phi$  to mean  $A_1\phi < f < A_2$  for some positive constants  $A_1$  and  $A_2$ .

$f = o(\phi)$  implies and is stronger than  $f = \mathcal{O}(\phi)$ .

Hardy, G. H. and Wright, E. M. "Some Notation." §1.6 in *An Introduction to the Theory of Numbers*, 5th ed. Oxford, England: Clarendon Press, pp. 7–8, 1979.

### Asymptotic Series

An asymptotic series is a SERIES EXPANSION of a FUNCTION in a variable  $x$  which may converge or diverge (Erdelyi 1987, p. 1), but whose partial sums can be made an arbitrarily good approximation to a given function for large enough  $x$ . To form an asymptotic series  $R(x)$  of  $f(x)$ , written

$$f(x) \sim R(x), \quad (1)$$

take

$$x^n R_n(x) = x^n [f(x) - S_n(x)], \quad (2)$$

where

$$S_n(x) \equiv a_0 + \frac{a_1}{x} + \frac{a_2}{x^2} + \dots + \frac{a_n}{x^n}. \quad (3)$$

The asymptotic series is defined to have the properties

$$\lim_{x \rightarrow \infty} x^n R_n(x) = 0 \quad \text{for fixed } n \quad (4)$$

$$\lim_{n \rightarrow \infty} x^n R_n(x) = \infty \quad \text{for fixed } x. \quad (5)$$

Therefore,

$$f(x) \approx \sum_{n=0}^{\infty} a_n x^{-n} \quad (6)$$

in the limit  $x \rightarrow \infty$ . If a function has an asymptotic expansion, the expansion is unique. The symbol  $\sim$  is also used to mean directly SIMILAR.

**Atkin-Goldwasser-Kilian-Morain Certificate**

A recursive PRIMALITY CERTIFICATE for a PRIME  $p$ . The certificate consists of a list of

1. A point on an ELLIPTIC CURVE  $C$

$$y^2 = x^3 + g_2x + g_3 \pmod{p}$$

for some numbers  $g_2$  and  $g_3$ .

2. A PRIME  $q$  with  $q > (p^{1/4} + 1)^2$ , such that for some other number  $k$  and  $m = kq$  with  $k \neq 1$ ,  $mC(x, y, g_2, g_3, p)$  is the identity on the curve, but  $kC(x, y, g_2, g_3, p)$  is not the identity. This guarantees PRIMALITY of  $p$  by a theorem of Goldwasser and Kilian (1986).
3. Each  $q$  has its recursive certificate following it. So if the smallest  $q$  is known to be PRIME, all the numbers are certified PRIME up the chain.

A PRATT CERTIFICATE is quicker to generate for small numbers. The *Mathematica*® (Wolfram Research, Champaign, IL) task `ProvablePrime[n]` therefore generates an Atkin-Goldwasser-Kilian-Morain certificate only for numbers above a certain limit ( $10^{10}$  by default), and a PRATT CERTIFICATE for smaller numbers.

**Atomic Statement**

In LOGIC, a statement which cannot be broken down into smaller statements.

**Attraction Basin**

see BASIN OF ATTRACTION

**Attractor**

An attractor is a SET of states (points in the PHASE SPACE), invariant under the dynamics, towards which neighboring states in a given BASIN OF ATTRACTION asymptotically approach in the course of dynamic evolution. An attractor is defined as the smallest unit which cannot be itself decomposed into two or more attractors

with distinct BASINS OF ATTRACTION. This restriction is necessary since a DYNAMICAL SYSTEM may have multiple attractors, each with its own BASIN OF ATTRACTION.

Conservative systems do not have attractors, since the motion is periodic. For dissipative DYNAMICAL SYSTEMS, however, volumes shrink exponentially so attractors have 0 volume in  $n$ -D phase space.

A stable FIXED POINT surrounded by a dissipative region is an attractor known as a SINK. Regular attractors (corresponding to 0 LYAPUNOV CHARACTERISTIC EXPONENTS) act as LIMIT CYCLES, in which trajectories circle around a limiting trajectory which they asymptotically approach, but never reach. STRANGE ATTRACTORS are bounded regions of PHASE SPACE (corresponding to POSITIVE LYAPUNOV CHARACTERISTIC EXPONENTS) having zero MEASURE in the embedding PHASE SPACE and a FRACTAL DIMENSION. Trajectories within a STRANGE ATTRACTOR appear to skip around randomly.

**Auction**

A type of sale in which members of a group of buyers offer ever increasing amounts. The bidder making the last bid (for which no higher bid is subsequently made within a specified time limit: "going once, going twice, sold") must then purchase the item in question at this price. Variants of simple bidding are also possible, as in a VICKERY AUCTION.

see also VICKERY AUCTION

**Augend**

The first of several ADDENDS, or "the one to which the others are added," is sometimes called the augend. Therefore, while  $a$ ,  $b$ , and  $c$  are ADDENDS in  $a + b + c$ ,  $a$  is the augend.

see also ADDEND, ADDITION

**Augmented Amicable Pair**

A PAIR of numbers  $m$  and  $n$  such that

$$\sigma(m) = \sigma(n) = m + n - 1,$$

where  $\sigma(m)$  is the DIVISOR FUNCTION. Beck and Najjar (1977) found 11 augmented amicable pairs.

### Aurifeuillean Factorization

A factorization of the form

$$2^{4n+2} + 1 = (2^{2n+1} - 2^{n+1} + 1)(2^{2n+1} + 2^{n+1} + 1). \quad (1)$$

The factorization for  $n = 14$  was discovered by Aurifeuille, and the general form was subsequently discovered by Lucas. The large factors are sometimes written as  $L$  and  $M$  as follows

$$2^{4k-2} + 1 = (2^{2k-1} - 2^k + 1)(2^{2k-1} + 2^k + 1) \quad (2)$$

$$3^{6k-3} + 1 = (3^{2k-1} + 1)(3^{2k-1} - 3^k + 1)(3^{2k-1} + 3^k + 1), \quad (3)$$

which can be written

$$2^{2h} + 1 = L_{2h}M_{2h} \quad (4)$$

$$3^{3h} + 1 = (3^h + 1)L_{3h}M_{3h} \quad (5)$$

$$5^{5h} - 1 = (5^h - 1)L_{5h}M_{5h}, \quad (6)$$

where  $h \equiv 2k - 1$  and

$$L_{2h}, M_{2h} = 2^h + 1 \mp 2^k \quad (7)$$

$$L_{3h}, M_{3h} = 3^h + 1 \mp 3^k \quad (8)$$

$$L_{5h}, M_{5h} = 5^{2h} + 3 \cdot 5^h + 1 \mp 5^k(5^h + 1). \quad (9)$$

### Authalic Latitude

AN AUXILIARY LATITUDE which gives a SPHERE equal SURFACE AREA relative to an ELLIPSOID. The authalic latitude is defined by

$$\beta = \sin^{-1} \left( \frac{q}{q_p} \right), \quad (1)$$

where

$$q \equiv (1 - e^2) \left[ \frac{\sin \phi}{1 - e^2 \sin^2 \phi} - \frac{1}{2e} \ln \left( \frac{1 - e \sin \phi}{1 + e \sin \phi} \right) \right], \quad (2)$$

and  $q_p$  is  $q$  evaluated at the north pole ( $\phi = 90^\circ$ ). Let  $R_q$  be the RADIUS of the SPHERE having the same SURFACE AREA as the ELLIPSOID, then

$$R_q = a \sqrt{\frac{q_p}{2}}. \quad (3)$$

The series for  $\beta$  is

$$\begin{aligned} \beta = \phi - & \left( \frac{1}{3}e^2 + \frac{31}{180}e^4 + \frac{59}{560}e^6 + \dots \right) \sin(2\phi) \\ & + \left( \frac{17}{360}e^4 + \frac{61}{1260}e^6 + \dots \right) \sin(4\phi) \\ & - \left( \frac{383}{45360}e^6 + \dots \right) \sin(6\phi) + \dots \end{aligned} \quad (4)$$

The inverse FORMULA is found from

$$\Delta\phi = \frac{(1 - e^2 \sin^2 \phi)^2}{2 \cos \phi} \left[ \frac{q}{1 - e^2} - \frac{\sin \phi}{1 - e^2 \sin^2 \phi} + \frac{1}{2e} \ln \left( \frac{1 - e \sin \phi}{1 + e \sin \phi} \right) \right], \quad (5)$$

where

$$q = q_p \sin \beta \quad (6)$$

and  $\phi_0 = \sin^{-1}(q/2)$ . This can be written in series form as

$$\begin{aligned}\phi = & \beta + \left(\frac{1}{3}e^2 + \frac{31}{180}e^4 + \frac{517}{5040}e^6 + \dots\right) \sin(2\beta) \\ & + \left(\frac{23}{360}e^4 + \frac{251}{3780}e^6 + \dots\right) \sin(4\beta) \\ & + \left(\frac{761}{45360}e^6 + \dots\right) \sin(6\beta) + \dots\end{aligned}\quad (7)$$

see also LATITUDE

#### Autocorrelation

The autocorrelation function is defined by

$$C_f(t) \equiv f \star f = f^*(-t) \star f(t) = \int_{-\infty}^{\infty} f^*(\tau) f(t + \tau) d\tau, \quad (1)$$

where  $\star$  denotes CONVOLUTION and  $\star$  denotes CROSS-CORRELATION. A finite autocorrelation is given by

$$C_f(\tau) \equiv \langle [y(t) - \bar{y}][y(t + \tau) - \bar{y}] \rangle \quad (2)$$

$$= \lim_{T \rightarrow \infty} \int_{-T/2}^{T/2} [y(t) - \bar{y}][y(t + \tau) - \bar{y}] dt. \quad (3)$$

If  $f$  is a REAL FUNCTION,

$$f^* = f, \quad (4)$$

and an EVEN FUNCTION so that

$$f(-\tau) = f(\tau), \quad (5)$$

then

$$C_f(t) = \int_{-\infty}^{\infty} f(\tau) f(t + \tau) d\tau. \quad (6)$$

But let  $\tau' \equiv -\tau$ , so  $d\tau' = -d\tau$ , then

$$\begin{aligned}C_f(t) &= \int_{\infty}^{-\infty} f(-\tau) f(t - \tau) (-d\tau) \\ &= \int_{-\infty}^{\infty} f(-\tau) f(t - \tau) d\tau \\ &= \int_{-\infty}^{\infty} f(\tau) f(t - \tau) d\tau = f \star f.\end{aligned}\quad (7)$$

The autocorrelation discards phase information, returning only the POWER. It is therefore not reversible.

There is also a somewhat surprising and extremely important relationship between the autocorrelation and

the FOURIER TRANSFORM known as the WIENER-KHINTCHINE THEOREM. Let  $\mathcal{F}[f(x)] = F(k)$ , and  $F^*$  denote the COMPLEX CONJUGATE of  $F$ , then the FOURIER TRANSFORM of the ABSOLUTE SQUARE of  $F(k)$  is given by

$$\mathcal{F}[|F(k)|^2] = \int_{-\infty}^{\infty} f^*(\tau) f(\tau + x) d\tau. \quad (8)$$

The autocorrelation is a HERMITIAN OPERATOR since  $C_f(-t) = C_f^*(t)$ .  $f \star f$  is MAXIMUM at the ORIGIN. In other words,

$$\int_{-\infty}^{\infty} f(u) f(u + x) du \leq \int_{-\infty}^{\infty} f^2(u) du. \quad (9)$$

To see this, let  $\epsilon$  be a REAL NUMBER. Then

$$\int_{-\infty}^{\infty} [f(u) + \epsilon f(u + x)]^2 du > 0 \quad (10)$$

$$\begin{aligned}\int_{-\infty}^{\infty} f^2(u) du + 2\epsilon \int_{-\infty}^{\infty} f(u) f(u + x) du \\ + \epsilon^2 \int_{-\infty}^{\infty} f^2(u + x) du > 0\end{aligned}\quad (11)$$

$$\begin{aligned}\int_{-\infty}^{\infty} f^2(u) du + 2\epsilon \int_{-\infty}^{\infty} f(u) f(u + x) du \\ + \epsilon^2 \int_{-\infty}^{\infty} f^2(u) du > 0.\end{aligned}\quad (12)$$

Define

$$a \equiv \int_{-\infty}^{\infty} f^2(u) du \quad (13)$$

$$b \equiv 2 \int_{-\infty}^{\infty} f(u) f(u + x) du. \quad (14)$$

Then plugging into above, we have  $ac^2 + bc + c > 0$ . This QUADRATIC EQUATION does not have any REAL ROOT, so  $b^2 - 4ac \leq 0$ , i.e.,  $b/2 \leq a$ . It follows that

$$\int_{-\infty}^{\infty} f(u) f(u + x) du \leq \int_{-\infty}^{\infty} f^2(u) du, \quad (15)$$

with the equality at  $x = 0$ . This proves that  $f \star f$  is MAXIMUM at the ORIGIN.

# Automorphic Function

An automorphic function  $f(z)$  of a COMPLEX variable  $z$  is one which is analytic (except for POLES) in a domain  $D$  and which is invariant under a DENUMERABLY INFINITE group of LINEAR FRACTIONAL TRANSFORMATIONS (also known as MÖBIUS TRANSFORMATIONS)

$$z' = \frac{az + b}{cz + d}.$$

Automorphic functions are generalizations of TRIGONOMETRIC FUNCTIONS and ELLIPTIC FUNCTIONS.

see also MODULAR FUNCTION, MÖBIUS TRANSFORMATIONS, ZETA FUCHSIAN

# Automorphic Number

A number  $k$  such that  $nk^2$  has its last digits equal to  $k$  is called  $n$ -automorphic. For example,  $1 \cdot 5^2 = 25$  and  $1 \cdot 6^2 = 36$  are 1-automorphic and  $2 \cdot 8^2 = 128$  and  $2 \cdot 88^2 = 15488$  are 2-automorphic. de Guerre and Fairbairn (1968) give a history of automorphic numbers.

The first few 1-automorphic numbers are 1, 5, 6, 25, 76, 376, 625, 9376, 90625, ... (Sloane's A003226, Wells 1986, p. 130). There are two 1-automorphic numbers with a given number of digits, one ending in 5 and one in 6 (except that the 1-digit automorphic numbers include 1), and each of these contains the previous number with a digit prepended. Using this fact, it is possible to construct automorphic numbers having more than 25,000 digits (Madachy 1979). The first few 1-automorphic numbers ending with 5 are 5, 25, 625, 0625, 90625, ... (Sloane's A007185), and the first few ending with 6 are 6, 76, 376, 9376, 09376, ... (Sloane's A016090). The 1-automorphic numbers  $a(n)$  ending in 5 are IDEMPOTENT (mod  $10^n$ ) since

$$[a(n)]^2 \equiv a(n) \pmod{10^n}$$

(Sloane and Plouffe 1995).

The following table gives the 10-digit  $n$ -automorphic numbers.

$n$	$n$ -Automorphic Numbers	Sloane

# Automorphism

An ISOMORPHISM of a system of objects onto itself.

see also ANOSOV AUTOMORPHISM

# Automorphism Group

The GROUP of functions from an object  $G$  to itself which preserve the structure of the object, denoted  $\text{Aut}(G)$ . The automorphism group of a GROUP preserves the MULTIPLICATION table, the automorphism group of a GRAPH the INCIDENCE MATRICES, and that of a FIELD the ADDITION and MULTIPLICATION tables.

see also OUTER AUTOMORPHISM GROUP

# Autonomous

A differential equation or system of ORDINARY DIFFERENTIAL EQUATIONS is said to be autonomous if it does not explicitly contain the independent variable (usually denoted  $t$ ). A second-order autonomous differential equation is of the form  $F(y, y', y'') = 0$ , where  $y' \equiv dy/dt \equiv v$ . By the CHAIN RULE,  $y''$  can be expressed as

$$y'' = v' = \frac{dv}{dt} = \frac{dv}{dy} \frac{dy}{dt} = \frac{dv}{dy} v.$$

For an autonomous ODE, the solution is independent of the time at which the initial conditions are applied. This means that all particles pass through a given point in phase space. A nonautonomous system of  $n$  first-order ODEs can be written as an autonomous system of  $n + 1$  ODEs by letting  $t \equiv x_{n+1}$  and increasing the dimension of the system by 1 by adding the equation

$$\frac{dx_{n+1}}{dt} = 1.$$

**Average Absolute Deviation**

$$\alpha \equiv \frac{1}{N} \sum_{i=1}^N |x_i - \mu| = \langle |x_i - \mu| \rangle.$$

see also ABSOLUTE DEVIATION, DEVIATION, STANDARD DEVIATION, VARIANCE

**Average Function**

If  $f$  is CONTINUOUS on a CLOSED INTERVAL  $[a, b]$ , then there is at least one number  $x^*$  in  $[a, b]$  such that

$$\int_a^b f(x) dx = f(x^*)(b - a).$$

The average value of the FUNCTION ( $\bar{f}$ ) on this interval is then given by  $f(x^*)$ .

see MEAN-VALUE THEOREM

**Average Seek Time**

see POINT-POINT DISTANCE—1-D

**Ax-Kochen Isomorphism Theorem**

Let  $P$  be the SET of PRIMES, and let  $\mathbb{Q}_p$  and  $Z_p(t)$  be the FIELDS of  $p$ -ADIC NUMBERS and formal POWER series over  $Z_p = (0, 1, \dots, p-1)$ . Further, suppose that  $D$  is a “nonprincipal maximal filter” on  $P$ . Then  $\prod_{p \in P} \mathbb{Q}_p/D$  and  $\prod_{p \in P} Z_p(t)/D$  are ISOMORPHIC.

see also HYPERREAL NUMBER, NONSTANDARD ANALYSIS

**Axial Vector**

see PSEUDOVECTOR

**Axiom**

A PROPOSITION regarded as self-evidently TRUE without PROOF. The word “axiom” is a slightly archaic synonym for POSTULATE. Compare CONJECTURE or HYPOTHESIS, both of which connote apparently TRUE but not self-evident statements.

see also ARCHIMEDES' AXIOM, AXIOM OF CHOICE, AXIOMATIC SYSTEM, CANTOR-DEDEKIND AXIOM, CONGRUENCE AXIOMS, CONJECTURE, CONTINUITY AXIOMS, COUNTABLE ADDITIVITY PROBABILITY AXIOM, DEDEKIND'S AXIOM, DIMENSION AXIOM, EILENBERG-STEENROD AXIOMS, EUCLID'S AXIOMS, EXCISION AXIOM, FANO'S AXIOM, FIELD AXIOMS, HAUSDORFF AXIOMS, HILBERT'S AXIOMS, HOMOTOPY AXIOM, INACCESSIBLE CARDINALS AXIOM, INCIDENCE AXIOMS, INDEPENDENCE AXIOM, INDUCTION AXIOM, LAW, LEMMA, LONG EXACT SEQUENCE OF A PAIR AXIOM, ORDERING AXIOMS, PARALLEL AXIOM, PASCH'S AXIOM, PEANO'S AXIOMS, PLAYFAIR'S AXIOM, PORISM, POSTULATE, PROBABILITY AXIOMS, PROCLUS' AXIOM, RULE, T2-SEPARATION AXIOM, THEOREM, ZERMELO'S AXIOM OF CHOICE, ZERMELO-FRAENKEL AXIOMS

**Axiom A Diffeomorphism**

Let  $\phi : M \rightarrow M$  be a  $C^1$  DIFFEOMORPHISM on a compact RIEMANNIAN MANIFOLD  $M$ . Then  $\phi$  satisfies Axiom A if the NONWANDERING set  $\Omega(\phi)$  of  $\phi$  is hyperbolic and the PERIODIC POINTS of  $\phi$  are DENSE in  $\Omega(\phi)$ . Although it was conjectured that the first of these conditions implies the second, they were shown to be independent in or around 1977. Examples include the ANOSOV DIFFEOMORPHISMS and SMALE HORSESHOE MAP.

In some cases, Axiom A can be replaced by the condition that the DIFFEOMORPHISM is a hyperbolic diffeomorphism on a hyperbolic set (Bowen 1975, Parry and Pollicott 1990).

**Axiom A Flow**

A FLOW defined analogously to the AXIOM A DIFFEOMORPHISM, except that instead of splitting the TANGENT BUNDLE into two invariant sub-BUNDLES, they are split into three (one exponentially contracting, one expanding, and one which is 1-dimensional and tangential to the flow direction).

see also DYNAMICAL SYSTEM

### Axiom of Choice

An important and fundamental result in SET THEORY sometimes called ZERMELO'S AXIOM OF CHOICE. It was formulated by Zermelo in 1904 and states that, given any SET of mutually exclusive nonempty SETS, there exists at least one SET that contains exactly one element in common with each of the nonempty SETS.

It is related to HILBERT'S PROBLEM 1B, and was proved to be consistent with other AXIOMS in SET THEORY in 1940 by Gödel. In 1963, Cohen demonstrated that the axiom of choice is independent of the other AXIOMS in Cantorian SET THEORY, so the AXIOM cannot be proved within the system (Boyer and Merzbacher 1991, p. 610).

### Axiomatic Set Theory

A version of SET THEORY in which axioms are taken as uninterpreted rather than as formalizations of pre-existing truths.

see also NAIVE SET THEORY, SET THEORY

### Axiomatic System

A logical system which possesses an explicitly stated SET of AXIOMS from which THEOREMS can be derived.

see also COMPLETE AXIOMATIC THEORY, CONSISTENCY, MODEL THEORY, THEOREM

### Axis

A LINE with respect to which a curve or figure is drawn, measured, rotated, etc. The term is also used to refer to a LINE SEGMENT through a RANGE (Woods 1961).

see also ABSCISSA, ORDINATE, x-AXIS, y-AXIS, z-AXIS

### Azimuthal Equidistant Projection

AN AZIMUTHAL PROJECTION which is neither equal-AREA nor CONFORMAL. Let  $\phi_1$  and  $\lambda_0$  be the LATITUDE and LONGITUDE of the center of the projection, then the transformation equations are given by

$$x = k' \cos \phi \sin(\lambda - \lambda_0) \quad (1)$$

$$y = k' [\cos \phi_1 \sin \phi - \sin \phi_1 \cos \phi \cos(\lambda - \lambda_0)] \quad (2)$$

Here,

$$k' = \frac{c}{\sin c} \quad (3)$$

and

$$\cos c = \sin \phi_1 \sin \phi + \cos \phi_1 \cos \phi \cos(\lambda - \lambda_0), \quad (4)$$

where  $c$  is the angular distance from the center. The inverse FORMULAS are

$$\phi = \sin^{-1} \left( \cos c \sin \phi_1 + \frac{y \sin c \cos \phi_1}{c} \right) \quad (5)$$

and

$$\lambda = \begin{cases} \lambda_0 + \tan^{-1} \left( \frac{x \sin c}{c \cos \phi_1 \cos c - y \sin \phi_1 \sin c} \right) & \text{for } \phi_1 \neq \pm 90^\circ \\ \lambda_0 + \tan^{-1} \left( -\frac{x}{y} \right) & \text{for } \phi_1 = 90^\circ \\ \lambda_0 + \tan^{-1} \left( \frac{x}{y} \right), & \text{for } \phi_1 = -90^\circ, \end{cases} \quad (6)$$

with the angular distance from the center given by

$$c = \sqrt{x^2 + y^2}. \quad (7)$$

# B

## $B^*$ -Algebra

A BANACH ALGEBRA with an ANTIAUTOMORPHIC INVOLUTION  $*$  which satisfies

$$x^{**} = x \quad (1)$$

$$x^*y^* = (yx)^* \quad (2)$$

$$x^* + y^* = (x + y)^* \quad (3)$$

$$(cx)^* = \bar{c}x^* \quad (4)$$

and whose NORM satisfies

$$\|xx^*\| = \|x\|^2. \quad (5)$$

A  $C^*$ -ALGEBRA is a special type of  $B^*$ -algebra.

see also BANACH ALGEBRA,  $C^*$ -ALGEBRA

## $B_2$ -Sequence

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Also called a SIDON SEQUENCE. An INFINITE SEQUENCE OF POSITIVE INTEGERS

$$1 \leq b_1 < b_2 < b_3 < \dots \quad (1)$$

such that all pairwise sums

$$b_i + b_j \quad (2)$$

for  $i \leq j$  are distinct (Guy 1994). An example is 1, 2, 4, 8, 13, 21, 31, 45, 66, 81, ... (Sloane's A005282).

Zhang (1993, 1994) showed that

$$S(B2) = \sup_{\text{all } B2 \text{ sequences}} \sum_{k=1}^{\infty} \frac{1}{b_k} > 2.1597. \quad (3)$$

The definition can be extended to  $B_n$ -sequences (Guy 1994).

see also A-SEQUENCE, MIAN-CHOWLA SEQUENCE

## $B_p$ -Theorem

If  $O_{p'}(G) = 1$  and if  $x$  is a  $p$ -element of  $G$ , then

$$L_{p'}(C_G(x)) \leq E(C_G(x)),$$

where  $L_{p'}$  is the  $p$ -LAYER.

## B-Spline

A generalization of the BÉZIER CURVE. Let a vector known as the KNOT VECTOR be defined

$$\mathbf{T} = \{t_0, t_1, \dots, t_m\}, \quad (1)$$

where  $\mathbf{T}$  is a nondecreasing SEQUENCE with  $t_i \in [0, 1]$ , and define control points  $\mathbf{P}_0, \dots, \mathbf{P}_n$ . Define the degree as

$$p \equiv m - n - 1. \quad (2)$$

The "knots"  $t_{p+1}, \dots, t_{m-p-1}$  are called INTERNAL KNOTS.

Define the basis functions as

$$N_{i,0}(t) = \begin{cases} 1 & \text{if } t_i \leq t < t_{i+1} \text{ and } t_i < t_{i+1} \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

$$N_{i,p}(t) = \frac{t - t_i}{t_{i+p} - t_i} N_{i,p-1}(t) + \frac{t_{i+p+1} - t}{t_{i+p+1} - t_{i+1}} N_{i+1,p-1}(t). \quad (4)$$

Then the curve defined by

$$\mathbf{C}(t) = \sum_{i=0}^n \mathbf{P}_i N_{i,p}(t) \quad (5)$$

is a B-spline. Specific types include the nonperiodic B-spline (first  $p + 1$  knots equal 0 and last  $p + 1$  equal to 1) and uniform B-spline (INTERNAL KNOTS are equally spaced). A B-Spline with no INTERNAL KNOTS is a BÉZIER CURVE.

The degree of a B-spline is independent of the number of control points, so a low order can always be maintained for purposes of numerical stability. Also, a curve is  $p - k$  times differentiable at a point where  $k$  duplicate knot values occur. The knot values determine the extent of the control of the control points.

A nonperiodic B-spline is a B-spline whose first  $p + 1$  knots are equal to 0 and last  $p + 1$  knots are equal to 1. A uniform B-spline is a B-spline whose INTERNAL KNOTS are equally spaced.

see also BÉZIER CURVE, NURBS CURVE

**B-Tree**

*B*-trees were introduced by Bayer (1972) and McCreight. They are a special *m*-ary balanced tree used in databases because their structure allows records to be inserted, deleted, and retrieved with guaranteed worst-case performance. An *n*-node *B*-tree has height  $\mathcal{O}(\lg 2)$ , where LG is the LOGARITHM to base 2. The Apple<sup>®</sup> Macintosh<sup>®</sup> (Apple Computer, Cupertino, CA) HFS filing system uses *B*-trees to store disk directories (Benedict 1995). A *B*-tree satisfies the following properties:

1. The ROOT is either a LEAF (TREE) or has at least two CHILDREN.
2. Each node (except the ROOT and LEAVES) has between  $\lceil m/2 \rceil$  and *m* CHILDREN, where  $\lceil x \rceil$  is the CEILING FUNCTION.
3. Each path from the ROOT to a LEAF (TREE) has the same length.

Every 2-3 TREE is a *B*-tree of order 3. The number of *B*-trees of order *n* = 1, 2, ... are 0, 1, 1, 2, 2, 3, 4, 5, 8, 14, 23, 32, 43, 63, ... (Ruskey, Sloane's A014535).

**BAC-CAB Identity**

The VECTOR TRIPLE PRODUCT identity

$$\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) = \mathbf{B}(\mathbf{A} \cdot \mathbf{C}) - \mathbf{C}(\mathbf{A} \cdot \mathbf{B}).$$

This identity can be generalized to *n*-D

$$\mathbf{a}_2 \times \cdots \times \mathbf{a}_{n-1} \times (\mathbf{b}_1 \times \cdots \times \mathbf{b}_{n-1}) \\ = (-1)^{n+1} \begin{vmatrix} \mathbf{b}_1 & \cdots & \mathbf{b}_{n-1} \\ \mathbf{a}_2 \cdot \mathbf{b}_1 & \cdots & \mathbf{a}_2 \cdot \mathbf{b}_{n-1} \\ \vdots & \ddots & \vdots \\ \mathbf{a}_{n-1} \cdot \mathbf{b}_1 & \cdots & \mathbf{a}_{n-1} \cdot \mathbf{b}_{n-1} \end{vmatrix}.$$

see also LAGRANGE'S IDENTITY

**BAC-CAB Rule**

**Bachet's Conjecture**

see LAGRANGE'S FOUR-SQUARE THEOREM

**Bachet Equation**

The DIOPHANTINE EQUATION

$$x^2 + k = y^3,$$

which is also an ELLIPTIC CURVE. The general equation is still the focus of ongoing study.

**Backhouse's Constant**

Let  $P(x)$  be defined as the POWER series whose *n*th term has a COEFFICIENT equal to the *n*th PRIME,

$$P(x) \equiv \sum_{k=0}^{\infty} p_k x^k = 1 + 2x + 3x^2 + 5x^3 + 7x^4 + 11x^5 + \cdots,$$

and let  $Q(x)$  be defined by

$$Q(x) = \frac{1}{P(x)} = \sum_{k=0}^{\infty} q_k x^k.$$

Then N. Backhouse conjectured that

$$\lim_{n \rightarrow \infty} \left| \frac{q_{n+1}}{q_n} \right| = 1.456074948582689671399595351116 \dots$$

The constant was subsequently shown to exist by P. Flajolet.

### Backward Difference

The backward difference is a FINITE DIFFERENCE defined by

$$\nabla_p \equiv \nabla f_p \equiv f_p - f_{p-1}. \quad (1)$$

Higher order differences are obtained by repeated operations of the backward difference operator, so

$$\nabla_p^2 = \nabla(\nabla p) = \nabla(f_p - f_{p-1}) = \nabla f_p - \nabla f_{p-1} \quad (2)$$

$$\begin{aligned} &= (f_p - f_{p-1}) - (f_{p-1} - f_{p-2}) \\ &= f_p - 2f_{p-1} + f_{p-2} \end{aligned} \quad (3)$$

In general,

$$\nabla_p^k \equiv \nabla^k f_p \equiv \sum_{m=0}^k (-1)^m \binom{k}{m} f_{p-k+m}, \quad (4)$$

where  $\binom{k}{m}$  is a BINOMIAL COEFFICIENT.

NEWTON'S BACKWARD DIFFERENCE FORMULA expresses  $f_p$  as the sum of the  $n$ th backward differences

$$f_p = f_0 + p\nabla_0 + \frac{1}{2!}p(p+1)\nabla_0^2 + \frac{1}{3!}p(p+1)(p+2)\nabla_0^3 + \dots, \quad (5)$$

where  $\nabla_0^n$  is the first  $n$ th difference computed from the difference table.

### Baguenaudier

A PUZZLE involving disentangling a set of rings from a looped double rod (also called CHINESE RINGS). The minimum number of moves needed for  $n$  rings is

$$\begin{cases} \frac{1}{3}(2^{n+1} - 2) & n \text{ even} \\ \frac{1}{3}(2^{n+1} - 1) & n \text{ odd.} \end{cases}$$

By simultaneously moving the two end rings, the number of moves can be reduced to

$$\begin{cases} 2^{n-1} - 1 & n \text{ even} \\ 2^{n-1} & n \text{ odd.} \end{cases}$$

The solution of the baguenaudier is intimately related to the theory of GRAY CODES.

### Bailey's Method

see LAMBERT'S METHOD

### Bailey's Theorem

Let  $\Gamma(z)$  be the GAMMA FUNCTION, then

$$\begin{aligned} &\left[ \frac{\Gamma(m + \frac{1}{2})}{\Gamma(m)} \right]^2 \underbrace{\left[ \frac{1}{m} + \left( \frac{1}{2} \right)^2 \frac{1}{m+1} + \left( \frac{1 \cdot 3}{2 \cdot 4} \right)^2 \frac{1}{m+2} + \dots \right]}_n \\ &= \left[ \frac{\Gamma(n + \frac{1}{2})}{\Gamma(n)} \right]^2 \underbrace{\left[ \frac{1}{n} + \left( \frac{1}{2} \right)^2 \frac{1}{n+1} + \left( \frac{1 \cdot 3}{2 \cdot 4} \right)^2 \frac{1}{n+2} + \dots \right]}_m. \end{aligned}$$

### Baire Category Theorem

A nonempty complete METRIC SPACE cannot be represented as the UNION of a COUNTABLE family of nowhere DENSE SUBSETS.

**Baire Space**

A TOPOLOGICAL SPACE  $X$  in which each SUBSET of  $X$  of the “first category” has an empty interior. A TOPOLOGICAL SPACE which is HOMEOMORPHIC to a complete METRIC SPACE is a Baire space.

**Bairstow's Method**

A procedure for finding the quadratic factors for the COMPLEX CONJUGATE ROOTS of a POLYNOMIAL  $P(x)$  with REAL COEFFICIENTS.

$$\begin{aligned} [x - (a + ib)][x - (a - ib)] \\ = x^2 + 2ax + (a^2 + b^2) \equiv x^2 + Bx + C. \end{aligned} \quad (1)$$

Now write the original POLYNOMIAL as

$$P(x) = (x^2 + Bx + C)Q(x) + Rx + S \quad (2)$$

$$R(B + \delta B, C + \delta C) \approx R(B, C) + \frac{\partial R}{\partial B} \delta B + \frac{\partial R}{\partial C} \delta C \quad (3)$$

$$S(B + \delta B, C + \delta C) \approx S(B, C) + \frac{\partial S}{\partial B} \delta B + \frac{\partial S}{\partial C} \delta C \quad (4)$$

$$\frac{\partial P}{\partial C} = 0 = (x^2 + Bx + C) \frac{\partial Q}{\partial C} + Q(x) + \frac{\partial R}{\partial C} + \frac{\partial S}{\partial C} \quad (5)$$

$$-Q(x) = (x^2 + Bx + C) \frac{\partial Q}{\partial C} + \frac{\partial R}{\partial C} + \frac{\partial S}{\partial C} \quad (6)$$

$$\frac{\partial P}{\partial B} = 0 = (x^2 + Bx + C) \frac{\partial Q}{\partial B} + xQ(x) + \frac{\partial R}{\partial B} + \frac{\partial S}{\partial B} \quad (7)$$

$$-xQ(x) = (x^2 + Bx + C) \frac{\partial Q}{\partial B} + \frac{\partial R}{\partial B} + \frac{\partial S}{\partial B} \quad (8)$$

Now use the 2-D NEWTON'S METHOD to find the simultaneous solutions.

**References**

Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. *Numerical Recipes in C: The Art of Scientific Computing*. Cambridge, England: Cambridge University Press, pp. 277 and 283–284, 1989.

**Baker's Dozen**

The number 13.

see also 13, DOZEN

**Baker's Map**

The MAP

$$x_{n+1} = 2\mu x_n, \quad (1)$$

where  $x$  is computed modulo 1. A generalized Baker's map can be defined as

$$x_{n+1} = \begin{cases} \lambda_a x_n & y_n < \alpha \\ (1 - \lambda_b) + \lambda_b x_n & y_n > \alpha \end{cases} \quad (2)$$

$$y_{n+1} = \begin{cases} \frac{y_n}{\alpha} & y_n < \alpha \\ \frac{y_n - \alpha}{\beta} & y_n > \alpha, \end{cases} \quad (3)$$

where  $\beta \equiv 1 - \alpha$ ,  $\lambda_a + \lambda_b \leq 1$ , and  $x$  and  $y$  are computed mod 1. The  $q = 1$   $q$ -DIMENSION is

$$D_1 = 1 + \frac{\alpha \ln\left(\frac{1}{\alpha}\right) + \beta \ln\left(\frac{1}{\beta}\right)}{\alpha \ln\left(\frac{1}{\lambda_a}\right) + \beta \ln\left(\frac{1}{\lambda_b}\right)}. \quad (4)$$

If  $\lambda_a = \lambda_b$ , then the general  $q$ -DIMENSION is

$$D_q = 1 + \frac{1}{q-1} \frac{\ln(\alpha^q + \beta^q)}{\ln \lambda_a}. \quad (5)$$

**Balanced ANOVA**

An ANOVA in which the number of REPLICATES (sets of identical observations) is restricted to be the same for each FACTOR LEVEL (treatment group).

see also ANOVA

**Balanced Incomplete Block Design**

see BLOCK DESIGN

**Ball**

The  $n$ -ball, denoted  $\mathbb{B}^n$ , is the interior of a SPHERE  $\mathbb{S}^{n-1}$ , and sometimes also called the  $n$ -DISK. (Although physicists often use the term “SPHERE” to mean the solid ball, mathematicians definitely do not!) Let  $\text{Vol}(\mathbb{B}^n)$  denote the volume of an  $n$ -D ball of RADIUS  $r$ . Then

$$\sum_{n=0}^{\infty} \text{Vol}(\mathbb{B}^n) = e^{\pi r^2} [1 + \text{erf}(r\sqrt{\pi})],$$

where  $\text{erf}(x)$  is the ERF function.

**References**

Freden, E. Problem 10207. “Summing a Series of Volumes.” *Amer. Math. Monthly* 100, 882, 1993.

**Ball Triangle Picking**

The determination of the probability for obtaining an OBTUSE TRIANGLE by picking 3 points at random in the unit DISK was generalized by Hall (1982) to the  $n$ -D BALL. Buchta (1986) subsequently gave closed form

evaluations for Hall's integrals, with the first few solutions being

$$P_2 = \frac{9}{8} - \frac{4}{\pi^2} \approx 0.72$$

$$P_3 = \frac{37}{70} \approx 0.53$$

$$P_4 \approx 0.39$$

$$P_5 \approx 0.29.$$

The case  $P_2$  corresponds to the usual DISK case.

### Ballot Problem

Suppose  $A$  and  $B$  are candidates for office and there are  $2n$  voters,  $n$  voting for  $A$  and  $n$  for  $B$ . In how many ways can the ballots be counted so that  $A$  is always ahead of or tied with  $B$ ? The solution is a CATALAN NUMBER  $C_n$ .

A related problem also called "the" ballot problem is to let  $A$  receive  $a$  votes and  $B$   $b$  votes with  $a > b$ . This version of the ballot problem then asks for the probability that  $A$  stays ahead of  $B$  as the votes are counted (Vardi 1991). The solution is  $(a - b)/(a + b)$ , as first shown by M. Bertrand (Hilton and Pedersen 1991). Another elegant solution was provided by André (1887) using the so-called ANDRÉ'S REFLECTION METHOD.

The problem can also be generalized (Hilton and Pedersen 1991). Furthermore, the TAK FUNCTION is connected with the ballot problem (Vardi 1991).

### Banach Algebra

An ALGEBRA  $A$  over a FIELD  $F$  with a NORM that makes  $A$  into a COMPLETE METRIC SPACE, and therefore, a BANACH SPACE.  $F$  is frequently taken to be the COMPLEX NUMBERS in order to assure that the SPECTRUM fully characterizes an OPERATOR (i.e., the spectral theorems for normal or compact normal operators do not, in general, hold in the SPECTRUM over the REAL NUMBERS).

see also  $B^*$ -ALGEBRA

### Banach Fixed Point Theorem

Let  $f$  be a contraction mapping from a closed SUBSET  $F$  of a BANACH SPACE  $E$  into  $F$ . Then there exists a unique  $z \in F$  such that  $f(z) = z$ .

see also FIXED POINT THEOREM

### Banach-Hausdorff-Tarski Paradox

see BANACH-TARSKI PARADOX

### Banach Measure

An "AREA" which can be defined for every set—even those without a true geometric AREA—which is rigid and finitely additive.

**Banach Space**

A normed linear SPACE which is COMPLETE in the norm-determined METRIC. A HILBERT SPACE is always a Banach space, but the converse need not hold.

see also BESOV SPACE, HILBERT SPACE, SCHAUDER FIXED POINT THEOREM

**Banach-Steinhaus Theorem**

see UNIFORM BOUNDEDNESS PRINCIPLE

**Banach-Tarski Paradox**

First stated in 1924, this theorem demonstrates that it is possible to dissect a BALL into six pieces which can be reassembled by rigid motions to form two balls of the same size as the original. The number of pieces was subsequently reduced to five. However, the pieces are extremely complicated. A generalization of this theorem is that any two bodies in  $\mathbb{R}^3$  which do not extend to infinity and each containing a ball of arbitrary size can be dissected into each other (they are EQUIDE-COMPOSABLE).

#### Barth Sextic

The Barth-sextic is a SEXTIC SURFACE in complex three-dimensional projective space having the maximum possible number of ORDINARY DOUBLE POINTS (65). It is given by the implicit equation

$$4(\phi^2 x^2 - y^2)(\phi^2 y^2 - z^2)(\phi^2 z^2 - x^2) \\ - (1 + 2\phi)(x^2 + y^2 + z^2 - w^2)^2 w^2 = 0.$$

where  $\phi$  is the GOLDEN MEAN, and  $w$  is a parameter (Endraß, Nordstrand), taken as  $w = 1$  in the above plot. The Barth sextic is invariant under the ICOSAEDRAL GROUP. Under the map

$$(x, y, z, w) \rightarrow (x^2, y^2, z^2, w^2),$$

the surface is the eightfold cover of the CAYLEY CUBIC (Endraß).

#### Bartlett Function

The APODIZATION FUNCTION

$$f(x) = 1 - \frac{|x|}{a} \quad (1)$$

which is a generalization of the one-argument TRIANGLE FUNCTION. Its FULL WIDTH AT HALF MAXIMUM is  $a$ . It has INSTRUMENT FUNCTION

$$I(x) = \int_{-a}^a e^{-2\pi i k x} \left(1 - \frac{|x|}{a}\right) dx \\ = \int_{-a}^0 e^{-2\pi i k x} \left(1 + \frac{x}{a}\right) dx \\ + \int_0^a e^{-2\pi i k x} \left(1 - \frac{x}{a}\right) dx. \quad (2)$$

Letting  $x' \equiv -x$  in the first part therefore gives

$$\int_{-a}^0 e^{-2\pi i k x} \left(1 + \frac{x}{a}\right) dx = \int_a^0 e^{2\pi i k x'} \left(1 - \frac{x'}{a}\right) (-dx') \\ = \int_0^a e^{2\pi i k x} \left(1 - \frac{x}{a}\right) dx. \quad (3)$$

Rewriting (2) using (3) gives

$$I(x) = (e^{2\pi i k x} + e^{-2\pi i k x}) \left(1 - \frac{x}{a}\right) dx \\ = 2 \int_0^a \cos(2\pi k x) \left(1 - \frac{x}{a}\right) dx. \quad (4)$$

Integrating the first part and using the integral

$$\int x \cos(bx) dx = \frac{1}{b^2} \cos(bx) + \frac{x}{b} \sin(bx) \quad (5)$$

for the second part gives

$$\begin{aligned}
 I(x) &= 2 \left[ \frac{\sin(2\pi kx)}{2\pi k} \right. \\
 &\quad \left. - \frac{1}{a} \left\{ \frac{1}{4\pi^2 k^2} \cos(2\pi kx) + \frac{x}{2\pi k} \sin(2\pi kx) \right\} \right]_0^a \\
 &= 2 \left\{ \left[ \frac{\sin(2\pi ka)}{2\pi k} - 0 \right] \right. \\
 &\quad \left. - \frac{1}{a} \left[ \frac{\cos(2\pi ka) - 1}{4\pi^2 k^2} + \frac{a \sin(2\pi ka)}{2\pi k} \right] \right\} \\
 &= \frac{1}{2\pi^2 a k^2} [\cos(2\pi ka) - 1] = a \frac{\sin^2(\pi ka)}{\pi^2 k^2 a^2} \\
 &= a \operatorname{sinc}^2(\pi ka), \tag{6}
 \end{aligned}$$

where  $\operatorname{sinc} x$  is the SINC FUNCTION. The peak (in units of  $a$ ) is 1. The function  $I(x)$  is always positive, so there are no NEGATIVE sidelobes. The extrema are given by letting  $\beta \equiv \pi ka$  and solving

$$\frac{d}{d\beta} \left( \frac{\sin \beta}{\beta} \right)^2 = 2 \frac{\sin \beta}{\beta} \frac{\sin \beta - \beta \cos \beta}{\beta^2} = 0 \tag{7}$$

$$\sin \beta (\sin \beta - \beta \cos \beta) = 0 \tag{8}$$

$$\sin \beta - \beta \cos \beta = 0 \tag{9}$$

$$\tan \beta = \beta. \tag{10}$$

Solving this numerically gives  $\beta = 4.49341$  for the first maximum, and the peak POSITIVE sidelobe is 0.047190. The full width at half maximum is given by setting  $x \equiv \pi ka$  and solving

$$\operatorname{sinc}^2 x = \frac{1}{2} \tag{11}$$

for  $x_{1/2}$ , yielding

$$x_{1/2} = \pi k_{1/2} a = 1.39156. \tag{12}$$

Therefore, with  $L \equiv 2a$ ,

$$\text{FWHM} = 2k_{1/2} = \frac{0.885895}{a} = \frac{1.77179}{L}. \tag{13}$$

#### Barycentric Coordinates

Also known as HOMOGENEOUS COORDINATES or TRILINEAR COORDINATES.

see TRILINEAR COORDINATES

#### Base Curve

see DIRECTRIX (RULED SURFACE)

#### Base (Logarithm)

The number used to define a LOGARITHM, which is then written  $\log_b$ . The symbol  $\log x$  is an abbreviation for  $\log_{10} x$ ,  $\ln x$  for  $\log_e x$  (the NATURAL LOGARITHM), and  $\lg x$  for  $\log_2 x$ .

see also E, LG, LN, LOGARITHM, NAPIERIAN LOGARITHM, NATURAL LOGARITHM

#### Base (Neighborhood System)

A base for a neighborhood system of a point  $x$  is a collection  $N$  of OPEN SETS such that  $x$  belongs to every member of  $N$ , and any OPEN SET containing  $x$  also contains a member of  $N$  as a SUBSET.

#### Base (Number)

A REAL NUMBER  $x$  can be represented using any INTEGER number  $b$  as a base (sometimes also called a RADIX or SCALE). The choice of a base yields to a representation of numbers known as a NUMBER SYSTEM. In base  $b$ , the DIGITS 0, 1, ...,  $b - 1$  are used (where, by convention, for bases larger than 10, the symbols A, B, C, ... are generally used as symbols representing the DECIMAL numbers 10, 11, 12, ...).

Base	Name
2	binary
3	ternary
4	quaternary
5	quinary
6	senary
7	septenary
8	octal
9	nonary
10	decimal
11	undenary
12	duodecimal
16	hexadecimal
20	vigesimal
60	sexagesimal

Let the base  $b$  representation of a number  $x$  be written

$$(a_n a_{n-1} \dots a_0 . a_{-1} \dots)_b, \tag{1}$$

(e.g.,  $123.456_{10}$ ), then the index of the leading DIGIT needed to represent the number is

$$n \equiv \lfloor \log_b x \rfloor, \tag{2}$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION. Now, recursively compute the successive DIGITS

$$a_i = \left\lfloor \frac{r_i}{b^i} \right\rfloor, \tag{3}$$

where  $r_n \equiv x$  and

$$r_{i-1} = r_i - a_i b^i \tag{4}$$

for  $i = n, n-1, \dots, 1, 0, \dots$ . This gives the base  $b$  representation of  $x$ . Note that if  $x$  is an INTEGER, then  $i$  need only run through 0, and that if  $x$  has a fractional part, then the expansion may or may not terminate. For example, the HEXADECIMAL representation of 0.1 (which terminates in DECIMAL notation) is the infinite expression  $0.19999\dots_h$ .

Some number systems use a mixture of bases for counting. Examples include the Mayan calendar and the old British monetary system (in which ha'pennies, pennies, threepence, sixpence, shillings, half crowns, pounds, and guineas corresponded to units of  $1/2, 1, 3, 6, 12, 30, 240$ , and 252, respectively).

Knuth has considered using TRANSCENDENTAL bases. This leads to some rather unfamiliar results, such as equating  $\pi$  to 1 in "base  $\pi$ ,"  $\pi = 1_\pi$ .

### Base Space

The SPACE  $B$  of a FIBER BUNDLE given by the MAP  $f: E \rightarrow B$ , where  $E$  is the TOTAL SPACE of the FIBER BUNDLE.

see also FIBER BUNDLE, TOTAL SPACE

### Baseball

The numbers 3 and 4 appear prominently in the game of baseball. There are  $3 \cdot 3 = 9$  innings in a game, and three strikes are an out. However, 4 balls are needed for a walk. The number of bases can either be regarded as 3 (excluding HOME PLATE) or 4 (including it).

see BASEBALL COVER, HOME PLATE

### Baseball Cover

A pair of identical plane regions (mirror symmetric about two perpendicular lines through the center) which can be stitched together to form a baseball (or tennis ball). A baseball has a CIRCUMFERENCE of  $9 \frac{1}{8}$  inches. The practical consideration of separating the regions far enough to allow the pitcher a good grip requires that the "neck" distance be about  $1 \frac{3}{16}$  inches. The baseball cover was invented by Elias Drake as a boy in the 1840s. (Thompson's attribution of the current design to trial and error development by C. H. Jackson in the 1860s is apparently unsubstantiated, as discovered by George Bart.)

One way to produce a baseball cover is to draw the regions on a SPHERE, then cut them out. However, it is difficult to produce two identical regions in this manner. Thompson (1996) gives mathematical expressions giving baseball cover curves both in the plane and in 3-D. J. H. Conway has humorously proposed the following "baseball curve conjecture:" no two definitions of "the" baseball curve will give the same answer unless their equivalence was obvious from the start.

see also BASEBALL, HOME PLATE, TENNIS BALL THEOREM, YIN-YANG

#### References

Thompson, R. B. "Designing a Baseball Cover. 1860's: Patience, Trial, and Error. 1990's: Geometry, Calculus, and Computation." <http://www.mathsoft.com/asolve/baseball/baseball.html>. Rev. March 5, 1996.

### Basin of Attraction

The set of points in the space of system variables such that initial conditions chosen in this set dynamically evolve to a particular ATTRACTOR.

see also WADA BASIN

### Basis

A (vector) basis is any SET of  $n$  LINEARLY INDEPENDENT VECTORS capable of generating an  $n$ -dimensional SUBSPACE of  $\mathbb{R}^n$ . Given a HYPERPLANE defined by

$$x_1 + x_2 + x_3 + x_4 + x_5 = 0,$$

a basis is found by solving for  $x_1$  in terms of  $x_2, x_3, x_4$ , and  $x_5$ . Carrying out this procedure,

$$x_1 = -x_2 - x_3 - x_4 - x_5,$$

so

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = x_2 \begin{bmatrix} -1 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix} + x_3 \begin{bmatrix} -1 \\ 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} + x_4 \begin{bmatrix} -1 \\ 0 \\ 0 \\ 1 \\ 0 \end{bmatrix} + x_5 \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \\ 1 \end{bmatrix},$$

and the above VECTOR form an (unnormalized) BASIS. Given a MATRIX  $A$  with an orthonormal basis, the MATRIX corresponding to a new basis, expressed in terms of the original  $\hat{x}_1, \dots, \hat{x}_n$  is

$$A' = [A\hat{x}_1 \quad \dots \quad A\hat{x}_n].$$

### Bauer's Identical Congruence

Let  $t(m)$  denote the set of the  $\phi(m)$  numbers less than and RELATIVELY PRIME to  $m$ , where  $\phi(n)$  is the TOTIENT FUNCTION. Define

$$f_m(x) \equiv \prod_{t(m)} (x - t). \quad (1)$$

A theorem of Lagrange states that

$$f_m(x) \equiv x^{\phi(m)} - 1 \pmod{m}. \quad (2)$$

This can be generalized as follows. Let  $p$  be an ODD PRIME DIVISOR of  $m$  and  $p^a$  the highest POWER which divides  $m$ , then

$$f_m(x) \equiv (x^{p-1} - 1)^{\phi(m)/(p-1)} \pmod{p^a} \quad (3)$$

and, in particular,

$$f_{p^a}(x) \equiv (x^{p-1} - 1)^{p^{a-1}} \pmod{p^a}. \quad (4)$$

Furthermore, if  $m > 2$  is EVEN and  $2^a$  is the highest POWER of 2 that divides  $m$ , then

$$f_m(x) \equiv (x^2 - 1)^{\phi(m)/2} \pmod{2^a} \quad (5)$$

and, in particular,

$$f_{2^a}(x) \equiv (x^2 - 1)^{2^{a-2}} \pmod{2^a}. \quad (6)$$

### Bayes' Formula

Let  $A$  and  $B_j$  be SETS. CONDITIONAL PROBABILITY requires that

$$P(A \cap B_j) = P(A)P(B_j|A), \quad (1)$$

where  $\cap$  denotes INTERSECTION ("and"), and also that

$$P(A \cap B_j) = P(B_j \cap A) = P(B_j)P(A|B_j) \quad (2)$$

and

$$P(B_j \cap A) = P(B_j)P(A|B_j). \quad (3)$$

Since (2) and (3) must be equal,

$$P(A \cap B_j) = P(B_j \cap A). \quad (4)$$

From (2) and (3),

$$P(A \cap B_j) = P(B_j)P(A|B_j). \quad (5)$$

Equating (5) with (2) gives

$$P(A)P(B_j|A) = P(B_j)P(A|B_j), \quad (6)$$

so

$$P(B_j|A) = \frac{P(B_j)P(A|B_j)}{P(A)}. \quad (7)$$

Now, let

$$S \equiv \bigcup_{i=1}^N A_i, \quad (8)$$

so  $A_i$  is an event in  $S$  and  $A_i \cap A_j = \emptyset$  for  $i \neq j$ , then

$$A = A \cap S = A \cap \left( \bigcup_{i=1}^N A_i \right) = \bigcup_{i=1}^N (A \cap A_i) \quad (9)$$

$$P(A) = P\left(\bigcup_{i=1}^N (A \cap A_i)\right) = \sum_{i=1}^N P(A \cap A_i). \quad (10)$$

From (5), this becomes

$$P(A) = \sum_{i=1}^N P(A_i)P(A|A_i), \quad (11)$$

so

$$P(A_i|A) = \frac{P(A_i)P(A|A_i)}{\sum_{j=1}^N P(A_j)P(A|A_j)}. \quad (12)$$

### Bayes' Theorem

see BAYES' FORMULA

### Bayesian Analysis

A statistical procedure which endeavors to estimate parameters of an underlying distribution based on the observed distribution. Begin with a "PRIOR DISTRIBUTION" which may be based on anything, including an assessment of the relative likelihoods of parameters or the results of non-Bayesian observations. In practice, it is common to assume a UNIFORM DISTRIBUTION over the appropriate range of values for the PRIOR DISTRIBUTION.

Given the PRIOR DISTRIBUTION, collect data to obtain the observed distribution. Then calculate the LIKELIHOOD of the observed distribution as a function of parameter values, multiply this likelihood function by the PRIOR DISTRIBUTION, and normalize to obtain a unit probability over all possible values. This is called the POSTERIOR DISTRIBUTION. The MODE of the distribution is then the parameter estimate, and "probability intervals" (the Bayesian analog of CONFIDENCE INTERVALS) can be calculated using the standard procedure. Bayesian analysis is somewhat controversial because the validity of the result depends on how valid the PRIOR DISTRIBUTION is, and this cannot be assessed statistically.

see also MAXIMUM LIKELIHOOD, PRIOR DISTRIBUTION, UNIFORM DISTRIBUTION

### Beam Detector

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

A “beam detector” for a given curve  $C$  is defined as a curve (or set of curves) through which every LINE tangent to or intersecting  $C$  passes. The shortest 1-arc beam detector, illustrated in the upper left figure, has length  $L_1 = \pi + 2$ . The shortest known 2-arc beam detector, illustrated in the right figure, has angles

$$\theta_1 \approx 1.286 \text{ rad} \quad (1)$$

$$\theta_2 \approx 1.191 \text{ rad}, \quad (2)$$

given by solving the simultaneous equations

$$2 \cos \theta_1 - \sin(\tfrac{1}{2}\theta_2) = 0 \quad (3)$$

$$\tan(\tfrac{1}{2}\theta_1) \cos(\tfrac{1}{2}\theta_2) + \sin(\tfrac{1}{2}\theta_2)[\sec^2(\tfrac{1}{2}\theta_2) + 1] = 2. \quad (4)$$

The corresponding length is

$$L_2 = 2\pi - 2\theta_1 - \theta_2 + 2 \tan(\tfrac{1}{2}\theta_1) + \sec(\tfrac{1}{2}\theta_2) - \cos(\tfrac{1}{2}\theta_2) + \tan(\tfrac{1}{2}\theta_1) \sin(\tfrac{1}{2}\theta_2) = 4.8189264563 \dots \quad (5)$$

A more complicated expression gives the shortest known 3-arc length  $L_3 = 4.799891547 \dots$ . Finch defines

$$L = \inf_{n \geq 1} L_n \quad (6)$$

as the beam detection constant, or the TRENCH DIGGERS’ CONSTANT. It is known that  $L \geq \pi$ .

#### Beast Number

The occult “number of the beast” associated in the Bible with the Antichrist. It has figured in many numerological studies. It is mentioned in Revelation 13:13: “Here is wisdom. Let him that hath understanding count the number of the beast: for it is the number of a man; and his number is 666.”

The beast number has several interesting properties which numerologists may find particularly interesting (Keith 1982–83). In particular, the beast number is equal to the sum of the squares of the first 7 PRIMES

$$2^2 + 3^2 + 5^2 + 7^2 + 11^2 + 13^2 + 17^2 = 666, \quad (1)$$

satisfies the identity

$$\phi(666) = 6 \cdot 6 \cdot 6, \quad (2)$$

where  $\phi$  is the TOTIENT FUNCTION, as well as the sum

$$\sum_{i=1}^{6 \cdot 6} i = 666. \quad (3)$$

The number 666 is a sum and difference of the first three 6th POWERS,

$$666 = 1^6 - 2^6 + 3^6 \quad (4)$$

(Keith). Another curious identity is that there are exactly two ways to insert “+” signs into the sequence 123456789 to make the sum 666, and exactly one way for the sequence 987654321,

$$666 = 1 + 2 + 3 + 4 + 567 + 89 = 123 + 456 + 78 + 9 \quad (5)$$

$$666 = 9 + 87 + 6 + 543 + 21 \quad (6)$$

(Keith). 666 is a REPDIGIT, and is also a TRIANGULAR NUMBER

$$T_{6 \cdot 6} = T_{36} = 666. \quad (7)$$

In fact, it is the largest REPDIGIT TRIANGULAR NUMBER (Bellew and Weger 1975–76). 666 is also a SMITH NUMBER. The first 144 DIGITS of  $\pi - 3$ , where  $\pi$  is P1, add to 666. In addition  $144 = (6 + 6) \times (6 + 6)$  (Blatner 1997).

A number of the form  $2^i$  which contains the digits of the beast number “666” is called an APOCALYPTIC NUMBER, and a number having 666 digits is called an APOCALYPSE NUMBER.

### Beatty Sequence

The Beatty sequence is a SPECTRUM SEQUENCE with an IRRATIONAL base. In other words, the Beatty sequence corresponding to an IRRATIONAL NUMBER  $\theta$  is given by  $[\theta]$ ,  $[2\theta]$ ,  $[3\theta]$ ,  $\dots$ , where  $[x]$  is the FLOOR FUNCTION. If  $\alpha$  and  $\beta$  are POSITIVE IRRATIONAL NUMBERS such that

$$\frac{1}{\alpha} + \frac{1}{\beta} = 1,$$

then the Beatty sequences  $[\alpha]$ ,  $[2\alpha]$ ,  $\dots$  and  $[\beta]$ ,  $[2\beta]$ ,  $\dots$  together contain all the POSITIVE INTEGERS without repetition.

## Bell Curve

see GAUSSIAN DISTRIBUTION, NORMAL DISTRIBUTION

## Bell Number

The number of ways a SET of  $n$  elements can be PARTITIONED into nonempty SUBSETS is called a BELL NUMBER and is denoted  $B_n$ . For example, there are five ways the numbers  $\{1, 2, 3\}$  can be partitioned:  $\{\{1\}, \{2\}, \{3\}\}$ ,  $\{\{1, 2\}, \{3\}\}$ ,  $\{\{1, 3\}, \{2\}\}$ ,  $\{\{1\}, \{2, 3\}\}$ , and  $\{\{1, 2, 3\}\}$ , so  $B_3 = 5$ .  $B_0 = 1$  and the first few Bell numbers for  $n = 1, 2, \dots$  are 1, 2, 5, 15, 52, 203, 877, 4140, 21147, 115975, ... (Sloane's A000110). Bell numbers are closely related to CATALAN NUMBERS.

The diagram below shows the constructions giving  $B_3 = 5$  and  $B_4 = 15$ , with line segments representing elements in the same SUBSET and dots representing subsets containing a single element (Dickau).

The INTEGERS  $B_n$  can be defined by the sum

$$B_n = \sum_{k=1}^n \left\{ \begin{matrix} n \\ k \end{matrix} \right\}, \quad (1)$$

where  $S_n^{(k)} = \left\{ \begin{matrix} n \\ k \end{matrix} \right\}$  is a STIRLING NUMBER OF THE SECOND KIND, or by the generating function

$$e^{e^x - 1} = \sum_{n=0}^{\infty} \frac{B_n}{n!} x^n. \quad (2)$$

The Bell numbers can also be generated using the BELL TRIANGLE, using the RECURRENCE RELATION

$$B_{n+1} = \sum_{k=0}^n B_k \binom{n}{k}, \quad (3)$$

where  $\binom{a}{b}$  is a BINOMIAL COEFFICIENT, or using the formula of Comtet (1974)

$$B_n = \left\lceil e^{-1} \sum_{m=1}^{2n} \frac{m^n}{m!} \right\rceil, \quad (4)$$

where  $\lceil x \rceil$  denotes the CEILING FUNCTION.

The Bell number  $B_n$  is also equal to  $\phi_n(1)$ , where  $\phi_n(x)$  is a BELL POLYNOMIAL. DOBIŃSKI'S FORMULA gives the  $n$ th Bell number

$$B_n = \frac{1}{e} \sum_{k=0}^{\infty} \frac{k^n}{k!}. \quad (5)$$

Lovász (1993) showed that this formula gives the asymptotic limit

$$B_n \sim n^{-1/2} [\lambda(n)]^{n+1/2} e^{\lambda(n) - n - 1}, \quad (6)$$

where  $\lambda(n)$  is defined implicitly by the equation

$$\lambda(n) \log[\lambda(n)] = n. \quad (7)$$

A variation of DOBIŃSKI'S FORMULA gives

$$B_k = \sum_{m=1}^n \frac{m^k}{m!} \sum_{s=0}^{n-m} \frac{(-1)^s}{s} \quad (8)$$

for  $1 \leq k \leq n$  (Pitman 1997). de Bruijn (1958) gave the asymptotic formula

$$\frac{\ln B_n}{n} = \ln n - \ln \ln n - 1 + \frac{\ln \ln n}{\ln n} + \frac{1}{\ln n} + \frac{1}{2} \left( \frac{\ln \ln n}{\ln n} \right)^2 + \mathcal{O} \left[ \frac{\ln \ln n}{(\ln n)^2} \right]. \quad (9)$$

TOUCHARD'S CONGRUENCE states

$$B_{p+k} \equiv B_k + B_{k+1} \pmod{p}, \quad (10)$$

when  $p$  is PRIME. The only PRIME Bell numbers for  $n \leq 1000$  are  $B_2, B_3, B_7, B_{13}, B_{42}$ , and  $B_{55}$ . The Bell numbers also have the curious property that

$$\begin{vmatrix} B_0 & B_1 & B_2 & \cdots & B_n \\ B_1 & B_2 & B_3 & \cdots & B_{n+1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ B_n & B_{n+1} & B_{n+2} & \cdots & B_{2n} \end{vmatrix} = \prod_{i=1}^n n! \quad (11)$$

(Lenard 1986).

**Bell Polynomial**

Two different GENERATING FUNCTIONS for the Bell polynomials for  $n > 0$  are given by

$$\phi_n(x) = e^{-x} \sum_{k=1}^{\infty} \frac{k^{n-1} x^k}{(k-1)!}$$

or

$$\phi_n(x) = x \sum_{k=1}^{n-1} \binom{n-1}{k-1} \phi_{k-1}(x),$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT.

The Bell polynomials are defined such that  $\phi_n(1) = B_n$ , where  $B_n$  is a BELL NUMBER. The first few Bell polynomials are

$$\begin{aligned}\phi_0(x) &= 1 \\ \phi_1(x) &= x \\ \phi_2(x) &= x + x^2 \\ \phi_3(x) &= x + 3x^2 + x^3 \\ \phi_4(x) &= x + 7x^2 + 6x^3 + x^4 \\ \phi_5(x) &= x + 15x^2 + 25x^3 + 10x^4 + x^5 \\ \phi_6(x) &= x + 31x^2 + 90x^3 + 65x^4 + 15x^5 + x^6.\end{aligned}$$

**Beltrami Field**

A VECTOR FIELD  $\mathbf{u}$  satisfying the vector identity

$$\mathbf{u} \times (\nabla \times \mathbf{u}) = 0$$

where  $\mathbf{A} \times \mathbf{B}$  is the CROSS PRODUCT and  $\nabla \times \mathbf{A}$  is the CURL is said to be a Beltrami field.

see also DIVERGENCELESS FIELD, IRROTATIONAL FIELD, SOLENOIDAL FIELD

**Beltrami Identity**

An identity in CALCULUS OF VARIATIONS discovered in 1868 by Beltrami. The EULER-LAGRANGE DIFFERENTIAL EQUATION is

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_x} \right) = 0. \quad (1)$$

Now, examine the DERIVATIVE of  $x$

$$\frac{df}{dx} = \frac{\partial f}{\partial y} y_x + \frac{\partial f}{\partial y_x} y_{xx} + \frac{\partial f}{\partial x}. \quad (2)$$

Solving for the  $\partial f / \partial y$  term gives

$$\frac{\partial f}{\partial y} y_x = \frac{df}{dx} - \frac{\partial f}{\partial y_x} y_{xx} - \frac{\partial f}{\partial x}. \quad (3)$$

Now, multiplying (1) by  $y_x$  gives

$$y_x \frac{\partial f}{\partial y} - y_x \frac{d}{dx} \left( \frac{\partial f}{\partial y_x} \right) = 0. \quad (4)$$

Substituting (3) into (4) then gives

$$\frac{df}{dx} - \frac{\partial f}{\partial y_x} y_{xx} - \frac{\partial f}{\partial x} - y_x \frac{d}{dx} \left( \frac{\partial f}{\partial y_x} \right) = 0 \quad (5)$$

$$-\frac{\partial f}{\partial x} + \frac{d}{dx} \left( f - y_x \frac{\partial f}{\partial y_x} \right) = 0. \quad (6)$$

This form is especially useful if  $f_x = 0$ , since in that case

$$\frac{d}{dx} \left( f - y_x \frac{\partial f}{\partial y_x} \right) = 0, \quad (7)$$

which immediately gives

$$f - y_x \frac{\partial f}{\partial y_x} = C, \quad (8)$$

where  $C$  is a constant of integration.

The Beltrami identity greatly simplifies the solution for the minimal AREA SURFACE OF REVOLUTION about a given axis between two specified points. It also allows straightforward solution of the BRACHISTOCHRONE PROBLEM.

see also BRACHISTOCHRONE PROBLEM, CALCULUS OF VARIATIONS, EULER-LAGRANGE DIFFERENTIAL EQUATION, SURFACE OF REVOLUTION

**Bend (Curvature)**

Given four mutually tangent circles, their bends are defined as the signed CURVATURES of the CIRCLES. If the contacts are all external, the signs are all taken as POSITIVE, whereas if one circle surrounds the other three, the sign of this circle is taken as NEGATIVE (Coxeter 1969).

**Benford's Law**

Also called the FIRST DIGIT LAW, FIRST DIGIT PHENOMENON, or LEADING DIGIT PHENOMENON. In listings, tables of statistics, etc., the DIGIT 1 tends to occur with PROBABILITY  $\sim 30\%$ , much greater than the expected 10%. This can be observed, for instance, by examining tables of LOGARITHMS and noting that the first pages are much more worn and smudged than later pages. The table below, taken from Benford (1938), shows the distribution of first digits taken from several disparate sources. Of the 54 million real constants in Plouffe's "Inverse Symbolic Calculator" database, 30% begin with the DIGIT 1.

Title	First Digit									#
	1	2	3	4	5	6	7	8	9	
Rivers, Area	31.0	16.4	10.7	11.3	7.2	8.6	5.5	4.2	5.1	335

In fact, the first SIGNIFICANT DIGIT seems to follow a LOGARITHMIC DISTRIBUTION, with

$$P(n) \approx \log(n+1) - \log n$$

for  $n = 1, \dots, 9$ . One explanation uses CENTRAL LIMIT-like theorems for the MANTISSAS of random variables under MULTIPLICATION. As the number of variables increases, the density function approaches that of a LOG-ARITHMIC DISTRIBUTION.

#### Bennequin's Conjecture

A BRAID with  $M$  strands and  $R$  components with  $P$  positive crossings and  $N$  negative crossings satisfies

$$|P - N| \leq 2U + M - R \leq P + N,$$

where  $U$  is the UNKNOTTING NUMBER. While the second part of the INEQUALITY was already known to be true (Boileau and Weber, 1983, 1984) at the time the conjecture was proposed, the proof of the entire conjecture was completed using results of Kronheimer and Mrowka on MILNOR'S CONJECTURE (and, independently, using MENASCO'S THEOREM).

#### Benson's Formula

An equation for a LATTICE SUM with  $n = 3$

$$\begin{aligned} -b_3(1) &= \sum'_{i,j,k=-\infty}^{\infty} \frac{(-1)^{i+j+k+1}}{\sqrt{i^2 + j^2 + k^2}} \\ &= 12\pi \sum_{m,n=1,3,\dots}^{\infty} \operatorname{sech}^2\left(\frac{1}{2}\pi\sqrt{m^2 + n^2}\right). \end{aligned}$$

Here, the prime denotes that summation over  $(0, 0, 0)$  is excluded. The sum is numerically equal to  $-1.74756\dots$ , a value known as "the" MADELUNG CONSTANT.

## Ber

The REAL PART of

$$J_\nu(xe^{3\pi i/4}) = \text{ber}_\nu(x) + i \text{bei}_\nu(x). \quad (1)$$

The special case  $\nu = 0$  gives

$$J_0(i\sqrt{x}) \equiv \text{ber}(x) + i \text{bei}(x), \quad (2)$$

where  $J_0$  is the zeroth order BESSEL FUNCTION OF THE FIRST KIND.

$$\text{ber}(x) \equiv \sum_{n=0}^{\infty} \frac{(-1)^n \left(\frac{x}{2}\right)^{2+4n}}{[(2n+1)!]^2}. \quad (3)$$

## Beraha Constants

The  $n$ th Beraha constant is given by

$$\text{Be}_n \equiv 2 + 2 \cos\left(\frac{2\pi}{n}\right).$$

The first few are

$$\begin{aligned} \text{Be}_1 &= 4 \\ \text{Be}_2 &= 0 \\ \text{Be}_3 &= 1 \\ \text{Be}_4 &= 2 \\ \text{Be}_5 &= \frac{1}{2}(3 + \sqrt{5}) \approx 2.618 \\ \text{Be}_6 &= 3 \\ \text{Be}_7 &= 2 + 2 \cos\left(\frac{2}{7}\pi\right) \approx 3.247 \dots \end{aligned}$$

They appear to be ROOTS of the CHROMATIC POLYNOMIALS of planar triangular GRAPHS.  $\text{Be}_4$  is  $\phi + 1$ , where  $\phi$  is the GOLDEN RATIO, and  $\text{Be}_7$  is the SILVER CONSTANT.

## Bergman Kernel

A Bergman kernel is a function of a COMPLEX VARIABLE with the "reproducing kernel" property defined for any DOMAIN in which there exist NONZERO ANALYTIC FUNCTIONS of class  $L_2(D)$  with respect to the LEBESGUE MEASURE  $dV$ .

## References

- Hazewinkel, M. (Managing Ed.). *Encyclopaedia of Mathematics: An Updated and Annotated Translation of the Soviet "Mathematical Encyclopaedia"*. Dordrecht, Netherlands: Reidel, pp. 356–357, 1988.

## Bergman Space

Let  $G$  be an open subset of the COMPLEX PLANE  $\mathbb{C}$ , and let  $L_a^2(G)$  denote the collection of all ANALYTIC FUNCTIONS  $f: G \rightarrow \mathbb{C}$  whose MODULUS is square integrable with respect to AREA measure. Then  $L_a^2(G)$ , sometimes also denoted  $A^2(G)$ , is called the Bergman space for  $G$ . Thus, the Bergman space consists of all the ANALYTIC FUNCTIONS in  $L^2(G)$ . The Bergman space can also be generalized to  $L_a^p(G)$ , where  $0 < p < \infty$ .

## Bernoulli Differential Equation

$$\frac{dy}{dx} + p(x)y = q(x)y^n. \quad (1)$$

Let  $v \equiv y^{1-n}$  for  $n \neq 1$ , then

$$\frac{dv}{dx} = (1-n)y^{-n} \frac{dy}{dx}. \quad (2)$$

Rewriting (1) gives

$$y^{-n} \frac{dy}{dx} = q(x) - p(x)y^{1-n} = q(x) - vp(x). \quad (3)$$

Plugging (3) into (2),

$$\frac{dv}{dx} = (1-n)[q(x) - vp(x)]. \quad (4)$$

Now, this is a linear FIRST-ORDER ORDINARY DIFFERENTIAL EQUATION of the form

$$\frac{dv}{dx} + vP(x) = Q(x), \quad (5)$$

where  $P(x) \equiv (1-n)p(x)$  and  $Q(x) \equiv (1-n)q(x)$ . It can therefore be solved analytically using an INTEGRATING FACTOR

$$\begin{aligned} v &= \frac{\int e^{\int P(x) dx} Q(x) dx + C}{e^{\int P(x) dx}} \\ &= \frac{(1-n) \int e^{(1-n) \int p(x) dx} q(x) dx + C}{e^{(1-n) \int p(x) dx}}, \end{aligned} \quad (6)$$

where  $C$  is a constant of integration. If  $n = 1$ , then equation (1) becomes

$$\frac{dy}{dx} = y(q-p) \quad (7)$$

$$\frac{dy}{y} = (q-p) dx \quad (8)$$

$$y = C_2 e^{\int [q(x)-p(x)] dx} \quad (9)$$

The general solution is then, with  $C_1$  and  $C_2$  constants,

$$y = \begin{cases} \left[ \frac{(1-n) \int e^{(1-n) \int p(x) dx} q(x) dx + C_1}{e^{(1-n) \int p(x) dx}} \right]^{1/(1-n)} & \text{for } n \neq 1 \\ C_2 e^{\int [q(x)-p(x)] dx} & \text{for } n = 1. \end{cases} \quad (10)$$

### Bernoulli Distribution

A DISTRIBUTION given by

$$P(n) = \begin{cases} q \equiv 1-p & \text{for } n = 0 \\ p & \text{for } n = 1 \end{cases} \quad (1)$$

$$= p^n(1-p)^{1-n} \quad \text{for } n = 0, 1. \quad (2)$$

The distribution of heads and tails in COIN TOSsing is a Bernoulli distribution with  $p = q = 1/2$ . The GENERATING FUNCTION of the Bernoulli distribution is

$$M(t) = \langle e^{tn} \rangle = \sum_{n=0}^1 e^{tn} p^n (1-p)^{1-n} = e^0(1-p) + e^t p, \quad (3)$$

so

$$M(t) = (1-p) + pe^t \quad (4)$$

$$M'(t) = pe^t \quad (5)$$

$$M''(t) = pe^t \quad (6)$$

$$M^{(n)}(t) = pe^t, \quad (7)$$

and the MOMENTS about 0 are

$$\mu'_1 = \mu = M'(0) = p \quad (8)$$

$$\mu'_2 = M''(0) = p \quad (9)$$

$$\mu'_n = M^{(n)}(0) = p. \quad (10)$$

The MOMENTS about the MEAN are

$$\mu_2 = \mu'_2 - (\mu'_1)^2 = p - p^2 = p(1-p) \quad (11)$$

$$\begin{aligned} \mu_3 &= \mu'_3 - 3\mu'_2\mu'_1 + 2(\mu'_1)^3 = p - 3p^2 + 2p^3 \\ &= p(1-p)(1-2p) \end{aligned} \quad (12)$$

$$\begin{aligned} \mu_4 &= \mu'_4 - 4\mu'_3\mu'_1 + 6\mu'_2(\mu'_1)^2 - 3(\mu'_1)^4 \\ &= p - 4p^2 + 6p^3 - 3p^4 \\ &= p(1-p)(3p^2 - 3p + 1). \end{aligned} \quad (13)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are then

$$\mu = \mu'_1 = p \quad (14)$$

$$\sigma^2 = \mu_2 = p(1-p) \quad (15)$$

$$\begin{aligned} \gamma_1 &= \frac{\mu_3}{\sigma^3} = \frac{p(1-p)(1-2p)}{[p(1-p)]^{3/2}} \\ &= \frac{1-2p}{\sqrt{p(1-p)}} \end{aligned} \quad (16)$$

$$\begin{aligned} \gamma_2 &= \frac{\mu_4}{\sigma^4} - 3 = \frac{p(1-2p)(2p^2 - 2p + 1)}{p^2(1-p)^2} - 3 \\ &= \frac{6p^2 - 6p + 1}{p(1-p)}. \end{aligned} \quad (17)$$

To find an estimator for a population mean,

$$\begin{aligned} \langle p \rangle &= \sum_{Np=0}^N p \binom{N}{Np} \theta^{Np} (1-\theta)^{Nq} \\ &= \theta \sum_{Np=1}^N \binom{N-1}{Np-1} \theta^{Np-1} (1-\theta)^{Nq} \\ &= \theta [\theta + (1-\theta)]^{N-1} = \theta, \end{aligned} \quad (18)$$

so  $\langle p \rangle$  is an UNBIASED ESTIMATOR for  $\theta$ . The probability of  $Np$  successes in  $N$  trials is then

$$\binom{N}{Np} \theta^{Np} (1-\theta)^{Nq}, \quad (19)$$

where

$$p = \frac{[\text{number of successes}]}{N} \equiv \frac{n}{N}. \quad (20)$$

see also BINOMIAL DISTRIBUTION

### Bernoulli Function

see BERNOULLI POLYNOMIAL

**Bernoulli Inequality**

$$(1+x)^n > 1+nx, \quad (1)$$

where  $x \in \mathbb{R} > -1 \neq 0$ ,  $n \in \mathbb{Z} > 1$ . This inequality can be proven by taking a MACLAURIN SERIES of  $(1+x)^n$ ,

$$(1+x)^n = 1+nx+\frac{1}{2}n(n-1)x^2+\frac{1}{6}n(n-1)(n-2)x^3+\dots \quad (2)$$

Since the series terminates after a finite number of terms for INTEGRAL  $n$ , the Bernoulli inequality for  $x > 0$  is obtained by truncating after the first-order term. When  $-1 < x < 0$ , slightly more finesse is needed. In this case, let  $y = |x| = -x > 0$  so that  $0 < y < 1$ , and take

$$(1-y)^n = 1-ny+\frac{1}{2}n(n-1)y^2-\frac{1}{6}n(n-1)(n-2)y^3+\dots \quad (3)$$

Since each POWER of  $y$  multiplies by a number  $< 1$  and since the ABSOLUTE VALUE of the COEFFICIENT of each subsequent term is smaller than the last, it follows that the sum of the third order and subsequent terms is a POSITIVE number. Therefore,

$$(1-y)^n > 1-ny, \quad (4)$$

or

$$(1+x)^n > 1+nx, \quad \text{for } -1 < x < 0, \quad (5)$$

completing the proof of the INEQUALITY over all ranges of parameters.

**Bernoulli Lemniscate**

see LEMNISCATE

**Bernoulli Number**

There are two definitions for the Bernoulli numbers. The older one, no longer in widespread use, defines the Bernoulli numbers  $B_n^*$  by the equations

$$\begin{aligned} \frac{x}{e^x-1} + \frac{x}{2} - 1 &\equiv \sum_{n=1}^{\infty} \frac{(-1)^{n-1} B_n^* x^{2n}}{(2n)!} \\ &= \frac{B_1^* x^2}{2!} - \frac{B_2^* x^4}{4!} + \frac{B_3^* x^6}{6!} + \dots \quad (1) \end{aligned}$$

for  $|x| < 2\pi$ , or

$$\begin{aligned} 1 - \frac{x}{2} \cot\left(\frac{x}{2}\right) &\equiv \sum_{n=1}^{\infty} \frac{B_n^* x^{2n}}{(2n)!} \\ &= \frac{B_1^* x^2}{2!} + \frac{B_2^* x^4}{4!} + \frac{B_3^* x^6}{6!} + \dots \quad (2) \end{aligned}$$

for  $|x| < \pi$  (Whittaker and Watson 1990, p. 125). Gradshcheyn and Ryzhik (1979) denote these numbers  $B_n^*$ , while Bernoulli numbers defined by the newer (National Bureau of Standards) definition are denoted  $B$ . The

$B_n^*$  Bernoulli numbers may be calculated from the integral

$$B_n^* = 4n \int_0^{\infty} \frac{t^{2n-1} dt}{e^{2\pi t} - 1}, \quad (3)$$

and analytically from

$$B_n^* = \frac{2(2n)!}{(2\pi)^{2n}} \sum_{p=1}^{\infty} p^{-2n} = \frac{2(2n)!}{(2\pi)^{2n}} \zeta(2n) \quad (4)$$

for  $n = 1, 2, \dots$ , where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION.

The first few Bernoulli numbers  $B_n^*$  are

$$\begin{aligned} B_1^* &= \frac{1}{6} \\ B_2^* &= \frac{1}{30} \\ B_3^* &= \frac{1}{42} \\ B_4^* &= \frac{1}{30} \\ B_5^* &= \frac{5}{66} \\ B_6^* &= \frac{691}{2,730} \\ B_7^* &= \frac{7}{6} \\ B_8^* &= \frac{3,617}{510} \\ B_9^* &= \frac{43,867}{798} \\ B_{10}^* &= \frac{174,611}{330} \\ B_{11}^* &= \frac{854,513}{138}. \end{aligned}$$

Bernoulli numbers defined by the modern definition are denoted  $B_n$  and also called “EVEN-index” Bernoulli numbers. These are the Bernoulli numbers returned by the *Mathematica*® (Wolfram Research, Champaign, IL) function `BernoulliB[n]`. These Bernoulli numbers are a superset of the archaic ones  $B_n^*$  since

$$B_n \equiv \begin{cases} 1 & \text{for } n = 0 \\ -\frac{1}{2} & \text{for } n = 1 \\ (-1)^{(n/2)-1} B_{n/2}^* & \text{for } n \text{ even} \\ 0 & \text{for } n \text{ odd.} \end{cases} \quad (5)$$

The  $B_n$  can be defined by the identity

$$\frac{x}{e^x-1} \equiv \sum_{n=0}^{\infty} \frac{B_n x^n}{n!}. \quad (6)$$

These relationships can be derived using the generating function

$$F(x, t) = \sum_{n=0}^{\infty} \frac{B_n(x) t^n}{n!}, \quad (7)$$

which converges uniformly for  $|t| < 2\pi$  and all  $x$  (Castellanos 1988). Taking the partial derivative gives

$$\frac{\partial F(x, t)}{\partial x} = \sum_{n=0}^{\infty} \frac{B_{n-1}(x) t^n}{(n-1)!} = t \sum_{n=0}^{\infty} \frac{B_n(x) t^n}{n!} = t F(x, t). \quad (8)$$

The solution to this differential equation is

$$F(x, t) = T(t)e^{xt}, \quad (9)$$

so integrating gives

$$\begin{aligned} \int_0^1 F(x, t) dx &= T(t) \int_0^1 e^{xt} dx = T(t) \frac{e^t - 1}{t} \\ &= \sum_{n=0}^{\infty} \frac{t^n}{n!} \int_0^1 B_n(x) dx \\ &= 1 + \sum_{n=1}^{\infty} \frac{t^n}{n!} \int_0^1 B_n(x) dx = 1 \quad (10) \end{aligned}$$

or

$$\frac{te^{xt}}{e^t - 1} = \sum_{n=0}^{\infty} \frac{B_n(x)t^n}{n!} \quad (11)$$

(Castellanos 1988). Setting  $x = 0$  and adding  $t/2$  to both sides then gives

$$\frac{1}{2}t \coth\left(\frac{1}{2}t\right) = \sum_{n=0}^{\infty} \frac{B_{2n}t^{2n}}{(2n)!}. \quad (12)$$

Letting  $t = 2ix$  then gives

$$x \cot x = \sum_{n=0}^{\infty} (-1)^n B_{2n} \frac{2x^{2n}}{(2n)!} \quad (13)$$

for  $x \in [-\pi, \pi]$ . The Bernoulli numbers may also be calculated from the integral

$$B_n = \frac{n!}{2\pi i} \int \frac{z}{e^z - 1} \frac{dz}{z^{n+1}}, \quad (14)$$

or from

$$B_n = \left[ \frac{d^n}{dx^n} \frac{x}{e^x - 1} \right]_{x=0}. \quad (15)$$

The Bernoulli numbers satisfy the identity

$$\binom{k+1}{1} B_k + \binom{k+1}{2} B_{k-1} + \dots + \binom{k+1}{k} B_1 + B_0 = 0, \quad (16)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. An asymptotic FORMULA is

$$\lim_{n \rightarrow \infty} |B_{2n}| \sim 4\sqrt{\pi n} \left( \frac{n}{\pi e} \right)^{2n}. \quad (17)$$

Bernoulli numbers appear in expressions of the form  $\sum_{k=1}^n k^p$ , where  $p = 1, 2, \dots$ . Bernoulli numbers also appear in the series expansions of functions involving  $\tan x$ ,  $\cot x$ ,  $\csc x$ ,  $\ln|\sin x|$ ,  $\ln|\cos x|$ ,  $\ln|\tan x|$ ,  $\tanh x$ ,

$\coth x$ , and  $\operatorname{csch} x$ . An analytic solution exists for EVEN orders,

$$B_{2n} = \frac{(-1)^{n-1} 2(2n)!}{(2\pi)^{2n}} \sum_{p=1}^{\infty} p^{-2n} = \frac{(-1)^{n-1} 2(2n)!}{(2\pi)^{2n}} \zeta(2n) \quad (18)$$

for  $n = 1, 2, \dots$ , where  $\zeta(2n)$  is the RIEMANN ZETA FUNCTION. Another intimate connection with the RIEMANN ZETA FUNCTION is provided by the identity

$$B_n = (-1)^{n+1} n \zeta(1-n). \quad (19)$$

The DENOMINATOR of  $B_{2k}$  is given by the VON STAUDT-CLAUSEN THEOREM

$$\operatorname{denom}(B_{2k}) = \prod_{\substack{p \text{ prime} \\ (p-1)|2k}}^{2k+1} p, \quad (20)$$

which also implies that the DENOMINATOR of  $B_{2k}$  is SQUAREFREE (Hardy and Wright 1979). Another curious property is that the fraction part of  $B_n$  in DECIMAL has a DECIMAL PERIOD which divides  $n$ , and there is a single digit before that period (Conway 1996).

$$\begin{aligned} B_0 &= 1 \\ B_1 &= -\frac{1}{2} \\ B_2 &= \frac{1}{6} \\ B_4 &= -\frac{1}{30} \\ B_6 &= \frac{1}{42} \\ B_8 &= -\frac{1}{30} \\ B_{10} &= \frac{5}{66} \\ B_{12} &= -\frac{691}{2,730} \\ B_{14} &= \frac{7}{6} \\ B_{16} &= -\frac{3,617}{510} \\ B_{18} &= \frac{43,867}{798} \\ B_{20} &= -\frac{174,611}{330} \\ B_{22} &= \frac{854,513}{138} \end{aligned}$$

(Sloane's A000367 and A002445). In addition,

$$B_{2n+1} = 0 \quad (21)$$

for  $n = 1, 2, \dots$ .

Bernoulli first used the Bernoulli numbers while computing  $\sum_{k=1}^n k^p$ . He used the property of the FIGURATE NUMBER TRIANGLE that

$$\sum_{i=0}^n a_{ij} = \frac{(n+1)a_{nj}}{j+1}, \quad (22)$$

along with a form for  $a_{nj}$  which he derived inductively to compute the sums up to  $n = 10$  (Boyer 1968, p. 85). For  $p \in \mathbb{Z} > 0$ , the sum is given by

$$\sum_{k=1}^n k^p = \sum_{k=1}^n \frac{(B+n+1)^{[p+1]} - B^{p+1}}{p+1}, \quad (23)$$

where the NOTATION  $B^{[k]}$  means the quantity in question is raised to the appropriate POWER  $k$ , and all terms of the form  $B^m$  are replaced with the corresponding Bernoulli numbers  $B_m$ . Written explicitly in terms of a sum of POWERS,

$$\sum_{k=1}^n k^p = \frac{B_k p!}{k!(p-k+1)!} n^{p-k+1}. \quad (24)$$

It is also true that the COEFFICIENTS of the terms in such an expansion sum to 1 (which Bernoulli stated without proof). Ramanujan gave a number of curious infinite sum identities involving Bernoulli numbers (Berndt 1994).

G. J. Fee and S. Plouffe have computed  $B_{200,000}$ , which has  $\sim 800,000$  DIGITS (Plouffe). Plouffe and collaborators have also calculated  $B_n$  for  $n$  up to 72,000.

#### Bernoulli's Paradox

Suppose the HARMONIC SERIES converges to  $h$ :

$$\sum_{k=1}^{\infty} \frac{1}{k} = h.$$

Then rearranging the terms in the sum gives

$$h - 1 = h,$$

which is a contradiction.

#### Bernoulli Polynomial

There are two definitions of Bernoulli polynomials in use. The  $n$ th Bernoulli polynomial is denoted here by  $B_n(x)$ , and the archaic Bernoulli polynomial by  $B_n^*(x)$ . These definitions correspond to the BERNOULLI NUMBERS evaluated at 0,

$$B_n \equiv B_n(0) \quad (1)$$

$$B_n^* \equiv B_n^*(0). \quad (2)$$

They also satisfy

$$B_n(1) = (-1)^n B_n(0) \quad (3)$$

and

$$B_n(1-x) = (-1)^n B_n(x) \quad (4)$$

(Lehmer 1988). The first few Bernoulli POLYNOMIALS are

$$\begin{aligned} B_0(x) &= 1 \\ B_1(x) &= x - \frac{1}{2} \\ B_2(x) &= x^2 - x + \frac{1}{6} \\ B_3(x) &= x^3 - \frac{3}{2}x^2 + \frac{1}{2}x \\ B_4(x) &= x^4 - 2x^3 + x^2 - \frac{1}{30} \\ B_5(x) &= x^5 - \frac{5}{2}x^4 + \frac{5}{3}x^3 - \frac{1}{6}x \\ B_6(x) &= x^6 - 3x^5 + \frac{5}{2}x^4 - \frac{1}{2}x^2 + \frac{1}{42}. \end{aligned}$$

Bernoulli (1713) defined the POLYNOMIALS in terms of sums of the POWERS of consecutive integers,

$$\sum_{k=0}^{m-1} k^{n-1} = \frac{1}{n} [B_n(m) - B_n(0)]. \quad (5)$$

Euler (1738) gave the Bernoulli POLYNOMIALS  $B_n(x)$  in terms of the generating function

$$\frac{te^{tx}}{e^t - 1} \equiv \sum_{n=0}^{\infty} B_n(x) \frac{t^n}{n!}. \quad (6)$$

They satisfy recurrence relation

$$\frac{dB_n}{dx} = nB_{n-1}(x) \quad (7)$$

(Appell 1882), and obey the identity

$$B_n(x) = (B + x)^n, \quad (8)$$

where  $B^k$  is interpreted here as  $B_k(x)$ . Hurwitz gave the FOURIER SERIES

$$B_n(x) = -\frac{n!}{(2\pi i)^n} \sum_{k=-\infty}^{\infty} k^{-n} e^{2\pi i k x}, \quad (9)$$

for  $0 < x < 1$ , and Raabe (1851) found

$$\frac{1}{m} \sum_{k=0}^{m-1} B_n \left( x + \frac{k}{m} \right) = m^{-n} B_n(mx). \quad (10)$$

A sum identity involving the Bernoulli POLYNOMIALS is

$$\sum_{k=0}^m \binom{m}{k} B_k(\alpha) B_{m-k}(\beta) = -(m-1)B_m(\alpha+\beta) + m(\alpha+\beta-1)B_{m-1}(\alpha+\beta) \quad (11)$$

for an INTEGER  $m$  and arbitrary REAL NUMBERS  $\alpha$  and  $\beta$ .

## Bernoulli's Theorem

see WEAK LAW OF LARGE NUMBERS

## Bernoulli Trial

An experiment in which  $s$  TRIALS are made of an event, with probability  $p$  of success in any given TRIAL.

## Bernstein-Bézier Curve

see BÉZIER CURVE

## Bernstein's Constant

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Let  $E_n(f)$  be the error of the best uniform approximation to a REAL function  $f(x)$  on the INTERVAL  $[-1, 1]$  by REAL POLYNOMIALS of degree at most  $n$ . If

$$\alpha(x) = |x|, \quad (1)$$

then Bernstein showed that

$$0.267 \dots < \lim_{n \rightarrow \infty} 2nE_{2n}(\alpha) < 0.286. \quad (2)$$

He conjectured that the lower limit ( $\beta$ ) was  $\beta = 1/(2\sqrt{\pi})$ . However, this was disproven by Varga and Carpenter (1987) and Varga (1990), who computed

$$\beta = 0.2801694990 \dots \quad (3)$$

For rational approximations  $p(x)/q(x)$  for  $p$  and  $q$  of degree  $m$  and  $n$ , D. J. Newman (1964) proved

$$\frac{1}{2}e^{-9\sqrt{n}} \leq E_{n,n}(\alpha) \leq 3e^{-\sqrt{n}} \quad (4)$$

for  $n \geq 4$ . Gonchar (1967) and Bulanov (1975) improved the lower bound to

$$e^{-\pi\sqrt{n+1}} \leq E_{n,n}(\alpha) \leq 3e^{-\sqrt{n}}. \quad (5)$$

Vjacheslavo (1975) proved the existence of POSITIVE constants  $m$  and  $M$  such that

$$m \leq e^{\pi\sqrt{n}} E_{n,n}(\alpha) < M \quad (6)$$

(Petrushev 1987, pp. 105–106). Varga *et al.* (1993) conjectured and Stahl (1993) proved that

$$\lim_{n \rightarrow \infty} e^{\pi\sqrt{2n}} E_{2n,2n}(\alpha) = 8. \quad (7)$$

**Berry Paradox**

There are several versions of the Berry paradox, the original version of which was published by Bertrand Russell and attributed to Oxford University librarian Mr. G. Berry. In one form, the paradox notes that the number "one million, one hundred thousand, one hundred and twenty one" can be named by the description: "the first number not nameable in under ten words." However, this latter expression has only nine words, so the number *can* be named in under ten words, so there is an inconsistency in naming it in this manner!

**Bertelsen's Number**

An erroneous value of  $\pi(10^9)$ , where  $\pi(x)$  is the PRIME COUNTING FUNCTION. Bertelsen's value of 50,847,478 is 56 lower than the correct value of 50,847,534.

References

Brown, K. S. "Bertelsen's Number." <http://www.seanet.com/~ksbrown/kmath049.htm>.

**Bertini's Theorem**

The general curve of a system which is LINEARLY INDEPENDENT on a certain number of given irreducible curves will not have a singular point which is not fixed for all the curves of the system.

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 115, 1959.

**Bertrand Curves**

Two curves which, at any point, have a common principal NORMAL VECTOR are called Bertrand curves. The product of the TORSIONS of Bertrand curves is a constant.

**Bertrand's Paradox**

see BERTRAND'S PROBLEM

**Bertrand's Postulate**

If  $n > 3$ , there is always at least one PRIME between  $n$  and  $2n - 2$ . Equivalently, if  $n > 1$ , then there is always at least one PRIME between  $n$  and  $2n$ . It was proved in 1850–51 by Chebyshev, and is therefore sometimes known as CHEBYSHEV'S THEOREM. An elegant proof was later given by Erdős. An extension of this result is that if  $n > k$ , then there is a number containing a PRIME divisor  $> k$  in the sequence  $n, n + 1, \dots, n + k - 1$ . (The case  $n = k + 1$  then corresponds to Bertrand's postulate.) This was first proved by Sylvester, independently by Schur, and a simple proof was given by Erdős.

A related problem is to find the least value of  $\theta$  so that there exists at least one PRIME between  $n$  and  $n + \mathcal{O}(n^\theta)$  for sufficiently large  $n$  (Berndt 1994). The smallest known value is  $\theta = 6/11 + \epsilon$  (Lou and Yao 1992).

**Bertrand's Problem**

What is the PROBABILITY that a CHORD drawn at RANDOM on a CIRCLE of RADIUS  $r$  has length  $\geq r$ ? The answer, it turns out, depends on the interpretation of "two points drawn at RANDOM." In the usual interpretation that ANGLES  $\theta_1$  and  $\theta_2$  are picked at RANDOM on the CIRCUMFERENCE,

$$P = \frac{\pi - \frac{\pi}{3}}{\pi} = \frac{2}{3}.$$

However, if a point is instead placed at RANDOM on a RADIUS of the CIRCLE and a CHORD drawn PERPENDICULAR to it,

$$P = \frac{\frac{\sqrt{3}}{2}r}{r} = \frac{\sqrt{3}}{2}.$$

The latter interpretation is more satisfactory in the sense that the result remains the same for a rotated CIRCLE, a slightly smaller CIRCLE INSCRIBED in the first, or for a CIRCLE of the same size but with its center slightly offset. Jaynes (1983) shows that the interpretation of "RANDOM" as a continuous UNIFORM DISTRIBUTION over the RADIUS is the only one possessing all these three invariances.

### Bertrand's Test

A CONVERGENCE TEST also called DE MORGAN'S AND BERTRAND'S TEST. If the ratio of terms of a SERIES  $\{a_n\}_{n=1}^{\infty}$  can be written in the form

$$\frac{a_n}{a_{n+1}} = 1 + \frac{1}{n} + \frac{\rho_n}{n \ln n},$$

then the series converges if  $\lim_{n \rightarrow \infty} \rho_n > 1$  and diverges if  $\lim_{n \rightarrow \infty} \rho_n < 1$ , where  $\lim_{n \rightarrow \infty}$  is the LOWER LIMIT and  $\lim_{n \rightarrow \infty}$  is the UPPER LIMIT.

see also KUMMER'S TEST

### Bessel's Correction

The factor  $(N-1)/N$  in the relationship between the VARIANCE  $\sigma$  and the EXPECTATION VALUES of the SAMPLE VARIANCE,

$$\langle s^2 \rangle = \frac{N-1}{N} \sigma^2, \quad (1)$$

where

$$s^2 \equiv \langle x^2 \rangle - \langle x \rangle^2. \quad (2)$$

For two samples,

$$\hat{\sigma}^2 = \frac{N_1 s_1^2 + N_2 s_2^2}{N_1 + N_2 - 2}. \quad (3)$$

see also SAMPLE VARIANCE, VARIANCE

### Bessel Differential Equation

$$x^2 \frac{d^2 y}{dx^2} + x \frac{dy}{dx} + (x^2 - m^2)y = 0. \quad (1)$$

Equivalently, dividing through by  $x^2$ ,

$$\frac{d^2 y}{dx^2} + \frac{1}{x} \frac{dy}{dx} + \left(1 - \frac{m^2}{x^2}\right)y = 0. \quad (2)$$

The solutions to this equation define the BESSEL FUNCTIONS. The equation has a regular SINGULARITY at 0 and an irregular SINGULARITY at  $\infty$ .

A transformed version of the Bessel differential equation given by Bowman (1958) is

$$x^2 \frac{d^2 y}{dx^2} + (2p+1)x \frac{dy}{dx} + (a^2 x^{2r} + \beta^2)y = 0. \quad (3)$$

The solution is

$$y = x^{-p} \left[ C_1 J_{q/r} \left( \frac{\alpha}{r} x^r \right) + C_2 Y_{q/r} \left( \frac{\alpha}{r} x^r \right) \right], \quad (4)$$

where

$$q \equiv \sqrt{p^2 - \beta^2}, \quad (5)$$

$J$  and  $Y$  are the BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS, and  $C_1$  and  $C_2$  are constants. Another form is given by letting  $y = x^{\alpha} J_n(\beta x^{\gamma})$ ,  $\eta = y x^{-\alpha}$ , and  $\xi = \beta x^{\gamma}$  (Bowman 1958, p. 117), then

$$\frac{d^2 y}{dx^2} - \frac{2\alpha-1}{x} \frac{dy}{dx} + \left( \beta^2 \gamma^2 x^{2\gamma-2} + \frac{\alpha^2 - n^2 \gamma^2}{x^2} \right) y = 0. \quad (6)$$

The solution is

$$y = \begin{cases} x^{\alpha} [A J_n(\beta x^{\gamma}) + B Y_n(\beta x^{\gamma})] & \text{for integral } n \\ A J_n(\beta x^{\gamma}) + B J_{-n}(\beta x^{\gamma}) & \text{for nonintegral } n. \end{cases} \quad (7)$$

**Bessel Function**

A function  $Z(x)$  defined by the RECURRENCE RELATIONS

$$Z_{m+1} + Z_{m-1} = \frac{2m}{x} Z_m$$

and

$$Z_{m+1} - Z_{m-1} = -2 \frac{dZ_m}{dx}.$$

*Bessel Function of the First Kind*

The Bessel functions are more frequently defined as solutions to the DIFFERENTIAL EQUATION

$$x^2 \frac{d^2 y}{dx^2} + x \frac{dy}{dx} + (x^2 - m^2)y = 0.$$

There are two classes of solution, called the BESSEL FUNCTION OF THE FIRST KIND  $J$  and BESSEL FUNCTION OF THE SECOND KIND  $Y$ . (A BESSEL FUNCTION OF THE THIRD KIND is a special combination of the first and second kinds.) Several related functions are also defined by slightly modifying the defining equations.

**Bessel Function of the First Kind**

The Bessel functions of the first kind  $J_n(x)$  are defined as the solutions to the BESSEL DIFFERENTIAL EQUATION

$$x^2 \frac{d^2 y}{dx^2} + x \frac{dy}{dx} + (x^2 - m^2)y = 0 \quad (1)$$

which are nonsingular at the origin. They are sometimes also called CYLINDER FUNCTIONS or CYLINDRICAL HARMONICS. The above plot shows  $J_n(x)$  for  $n = 1, 2, \dots, 5$ .

To solve the differential equation, apply FROBENIUS METHOD using a series solution of the form

$$y = x^k \sum_{n=0}^{\infty} a_n x^n = \sum_{n=0}^{\infty} a_n x^{n+k}. \quad (2)$$

Plugging into (1) yields

$$\begin{aligned} x^2 \sum_{n=0}^{\infty} (k+n)(k+n-1) a_n x^{k+n-2} \\ + x \sum_{n=0}^{\infty} (k+n) a_n x^{k+n-1} + x^2 \sum_{n=0}^{\infty} a_n x^{k+n} \\ - m^2 \sum_{n=0}^{\infty} a_n x^{n+k} = 0 \end{aligned} \quad (3)$$

$$\begin{aligned} \sum_{n=0}^{\infty} (k+n)(k+n-1) a_n x^{k+n} + \sum_{n=0}^{\infty} (k+n) a_n x^{k+n} \\ + \sum_{n=2}^{\infty} a_{n-2} x^{k+n} - m^2 \sum_{n=0}^{\infty} a_n x^{n+k} = 0. \end{aligned} \quad (4)$$

The INDICIAL EQUATION, obtained by setting  $n = 0$ , is

$$a_0[k(k-1) + k - m^2] = a_0(k^2 - m^2) = 0. \quad (5)$$

Since  $a_0$  is defined as the first NONZERO term,  $k^2 - m^2 = 0$ , so  $k = \pm m$ . Now, if  $k = m$ ,

$$\begin{aligned} \sum_{n=0}^{\infty} [(m+n)(m+n-1) + (m+n) - m^2] a_n x^{m+n} \\ + \sum_{n=2}^{\infty} a_{n-2} x^{m+n} = 0 \end{aligned} \quad (6)$$

$$\sum_{n=0}^{\infty} [(m+n)^2 - m^2] a_n x^{m+n} + \sum_{n=2}^{\infty} a_{n-2} x^{m+n} = 0 \quad (7)$$

$$\sum_{n=0}^{\infty} n(2m+n) a_n x^{m+n} + \sum_{n=2}^{\infty} a_{n-2} x^{m+n} = 0 \quad (8)$$

$$a_1(2m+1) + \sum_{n=2}^{\infty} [a_n n(2m+n) + a_{n-2}] x^{m+n} = 0. \quad (9)$$

First, look at the special case  $m = -1/2$ , then (9) becomes

$$\sum_{n=2}^{\infty} [a_n n(n-1) + a_{n-2}] x^{m+n} = 0, \quad (10)$$

so

$$a_n = -\frac{1}{n(n-1)} a_{n-2}. \quad (11)$$

Now let  $n = 2l$ , where  $l = 1, 2, \dots$

$$\begin{aligned} a_{2l} &= -\frac{1}{2l(2l-1)} a_{2l-2} \\ &= \frac{(-1)^l}{[2l(2l-1)][2(l-1)(2l-3)] \dots [2 \cdot 1 \cdot 1]} a_0 \\ &= \frac{(-1)^l}{2^l l! (2l-1)!} a_0, \end{aligned} \quad (12)$$

which, using the identity  $2^l l! (2l-1)! = (2l)!$ , gives

$$a_{2l} = \frac{(-1)^l}{(2l)!} a_0. \quad (13)$$

Similarly, letting  $n = 2l+1$

$$\begin{aligned} a_{2l+1} &= -\frac{1}{(2l+1)(2l)} a_{2l-1} \\ &= \frac{(-1)^l}{[2l(2l+1)][2(l-1)(2l-1)] \dots [2 \cdot 1 \cdot 3][1]} a_1, \end{aligned} \quad (14)$$

which, using the identity  $2^l l! (2l+1)! = (2l+1)!$ , gives

$$a_{2l+1} = \frac{(-1)^l}{2^l l! (2l+1)!} a_1 = \frac{(-1)^l}{(2l+1)!} a_1. \quad (15)$$

Plugging back into (2) with  $k = m = -1/2$  gives

$$\begin{aligned} y &= x^{-1/2} \sum_{n=0}^{\infty} a_n x^n \\ &= x^{-1/2} \left[ \sum_{n=1,3,5,\dots}^{\infty} a_n x^n + \sum_{n=0,2,4,\dots}^{\infty} a_n x^n \right] \\ &= x^{-1/2} \left[ \sum_{l=0}^{\infty} a_{2l} x^{2l} + \sum_{l=0}^{\infty} a_{2l+1} x^{2l+1} \right] \\ &= x^{-1/2} \left[ a_0 \sum_{l=0}^{\infty} \frac{(-1)^l}{(2l)!} x^{2l} + a_1 \sum_{l=0}^{\infty} \frac{(-1)^l}{(2l+1)!} x^{2l+1} \right] \\ &= x^{-1/2} (a_0 \cos x + a_1 \sin x). \end{aligned} \quad (16)$$

The BESSEL FUNCTIONS of order  $\pm 1/2$  are therefore defined as

$$J_{-1/2}(x) \equiv \sqrt{\frac{2}{\pi x}} \cos x \quad (17)$$

$$J_{1/2}(x) \equiv \sqrt{\frac{2}{\pi x}} \sin x, \quad (18)$$

so the general solution for  $m = \pm 1/2$  is

$$y = a'_0 J_{-1/2}(x) + a'_1 J_{1/2}(x). \quad (19)$$

Now, consider a general  $m \neq -1/2$ . Equation (9) requires

$$a_1(2m+1) = 0 \quad (20)$$

$$[a_n n(2m+n) + a_{n-2}]x^{m+n} = 0 \quad (21)$$

for  $n = 2, 3, \dots$ , so

$$a_1 = 0 \quad (22)$$

$$a_n = -\frac{1}{n(2m+n)} a_{n-2} \quad (23)$$

for  $n = 2, 3, \dots$ . Let  $n \equiv 2l+1$ , where  $l = 1, 2, \dots$ , then

$$\begin{aligned} a_{2l+1} &= -\frac{1}{(2l+1)[2(m+1)+1]} a_{2l-1} \\ &= \dots = f(n, m) a_1 = 0, \end{aligned} \quad (24)$$

where  $f(n, m)$  is the function of  $l$  and  $m$  obtained by iterating the recursion relationship down to  $a_1$ . Now let  $n \equiv 2l$ , where  $l = 1, 2, \dots$ , so

$$\begin{aligned} a_{2l} &= -\frac{1}{2l(2m+2l)} a_{2l-2} = -\frac{1}{4l(m+l)} a_{2l-2} \\ &= \frac{(-1)^l}{[4l(m+l)][4(l-1)(m+l-1)] \dots [4 \cdot (m+1)]} a_0. \end{aligned} \quad (25)$$

Plugging back into (9),

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^{n+m} = \sum_{n=1,3,5,\dots}^{\infty} a_n x^{n+m} + \sum_{n=0,2,4,\dots}^{\infty} a_n x^{n+m} \\ &= \sum_{l=0}^{\infty} a_{2l+1} x^{2l+m+1} + \sum_{l=0}^{\infty} a_{2l} x^{2l+m} \\ &= a_0 \sum_{l=0}^{\infty} \frac{(-1)^l}{[4l(m+l)][4(l-1)(m+l-1)] \dots [4 \cdot (m+1)]} x^{2l+m} \\ &= a_0 \sum_{l=0}^{\infty} \frac{[(-1)^l m(m-1) \dots 1] x^{2l+m}}{[4l(m+l)][4(l-1)(m+l-1)] \dots [m(m-1) \dots 1]} \\ &= a_0 \sum_{l=0}^{\infty} \frac{(-1)^l m!}{4^l l! (m+l)!} = a_0 \sum_{l=0}^{\infty} \frac{(-1)^l m!}{2^{2l} l! (m+l)!}. \end{aligned} \quad (26)$$

Now define

$$J_m(x) \equiv \sum_{l=0}^{\infty} \frac{(-1)^l}{2^{2l+m} l! (m+l)!} x^{2l+m}, \quad (27)$$

where the factorials can be generalized to GAMMA FUNCTIONS for nonintegral  $m$ . The above equation then becomes

$$y = a_0 2^m m! J_m(x) = a'_0 J_m(x). \quad (28)$$

Returning to equation (5) and examining the case  $k = -m$ ,

$$a_1(1-2m) + \sum_{n=2}^{\infty} [a_n n(n-2m) + a_{n-2}] x^{n-m} = 0. \quad (29)$$

However, the sign of  $m$  is arbitrary, so the solutions must be the same for  $+m$  and  $-m$ . We are therefore free to replace  $-m$  with  $-|m|$ , so

$$a_1(1+2|m|) + \sum_{n=2}^{\infty} [a_n n(n+2|m|) + a_{n-2}] x^{|m|+n} = 0, \quad (30)$$

and we obtain the same solutions as before, but with  $m$  replaced by  $|m|$ .

$$J_m(x) = \begin{cases} \sum_{l=0}^{\infty} \frac{(-1)^l}{2^{2l+|m|} l! (|m|+l)!} x^{2l+|m|} & \text{for } |m| \neq -\frac{1}{2} \\ \sqrt{\frac{2}{\pi x}} \cos x & \text{for } m = -\frac{1}{2} \\ \sqrt{\frac{2}{\pi x}} \sin x & \text{for } m = \frac{1}{2}. \end{cases} \quad (31)$$

We can relate  $J_m$  and  $J_{-m}$  (when  $m$  is an INTEGER) by writing

$$J_{-m}(x) = \sum_{l=0}^{\infty} \frac{(-1)^l}{2^{2l-m} l! (l-m)!} x^{2l-m}. \quad (32)$$

Now let  $l \equiv l' + m$ . Then

$$\begin{aligned} J_{-m}(x) &= \sum_{l'+m=0}^{\infty} \frac{(-1)^{l'+m}}{2^{2l'+m} (l'+m)! l!} x^{2l'+m} \\ &= \sum_{l'=-m}^{-1} \frac{(-1)^{l'+m}}{2^{2l'+m} l'! (l'+m)!} x^{2l'+m} \\ &\quad + \sum_{l'=0}^{\infty} \frac{(-1)^{l'+m}}{2^{2l'+m} l'! (l'+m)!} x^{2l'+m}. \end{aligned} \quad (33)$$

But  $l'! = \infty$  for  $l' = -m, \dots, -1$ , so the DENOMINATOR is infinite and the terms on the right are zero. We therefore have

$$J_{-m}(x) = \sum_{l=0}^{\infty} \frac{(-1)^{l+m}}{2^{2l+m} l! (l+m)!} x^{2l+m} = (-1)^m J_m(x). \quad (34)$$

Note that the BESSEL DIFFERENTIAL EQUATION is second-order, so there must be two linearly independent solutions. We have found both only for  $|m| = 1/2$ . For a general nonintegral order, the independent solutions are  $J_m$  and  $J_{-m}$ . When  $m$  is an INTEGER, the general (real) solution is of the form

$$Z_m \equiv C_1 J_m(x) + C_2 Y_m(x), \quad (35)$$

where  $J_m$  is a Bessel function of the first kind,  $Y_m$  (a.k.a.  $N_m$ ) is the BESSEL FUNCTION OF THE SECOND KIND (a.k.a. NEUMANN FUNCTION or WEBER FUNCTION), and  $C_1$  and  $C_2$  are constants. Complex solutions are given by the HANKEL FUNCTIONS (a.k.a. BESSEL FUNCTIONS OF THE THIRD KIND).

The Bessel functions are ORTHOGONAL in  $[0, 1]$  with respect to the weight factor  $x$ . Except when  $2n$  is a NEGATIVE INTEGER,

$$J_m(z) = \frac{z^{-1/2}}{2^{2m+1/2} i^{m+1/2} \Gamma(m+1)} M_{0,m}(2iz), \quad (36)$$

where  $\Gamma(x)$  is the GAMMA FUNCTION and  $M_{0,m}$  is a WHITTAKER FUNCTION.

In terms of a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND, the Bessel function is written

$$J_\nu(z) = \frac{(\frac{1}{2}z)^\nu}{\Gamma(\nu+1)} {}_0F_1(\nu+1; -\frac{1}{4}z^2). \quad (37)$$

A derivative identity for expressing higher order Bessel functions in terms of  $J_0(x)$  is

$$J_n(x) = i^n T_n \left( i \frac{d}{dx} \right) J_0(x), \quad (38)$$

where  $T_n(x)$  is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND. Asymptotic forms for the Bessel functions are

$$J_m(x) \approx \frac{1}{\Gamma(m+1)} \left( \frac{x}{2} \right)^m \quad (39)$$

for  $x \ll 1$  and

$$J_m(x) \approx \sqrt{\frac{2}{\pi x}} \cos \left( x - \frac{m\pi}{2} - \frac{\pi}{4} \right) \quad (40)$$

for  $x \gg 1$ . A derivative identity is

$$\frac{d}{dx} [x^m J_m(x)] = x^m J_{m-1}(x). \quad (41)$$

An integral identity is

$$\int_0^u u' J_0(u') du' = u J_1(u). \quad (42)$$

Some sum identities are

$$1 = [J_0(x)]^2 + 2[J_1(x)]^2 + 2[J_2(x)]^2 + \dots \quad (43)$$

$$1 = J_0(x) + 2J_2(x) + 2J_4(x) + \dots \quad (44)$$

and the JACOBI-ANGER EXPANSION

$$e^{iz \cos \theta} = \sum_{n=-\infty}^{\infty} i^n J_n(z) e^{in\theta}, \quad (45)$$

which can also be written

$$e^{iz \cos \theta} = J_0(z) + 2 \sum_{n=1}^{\infty} i^n J_n(z) \cos(n\theta). \quad (46)$$

The Bessel function addition theorem states

$$J_n(y+z) = \sum_{m=-\infty}^{\infty} J_m(y) J_{n-m}(z). \quad (47)$$

ROOTS of the FUNCTION  $J_n(x)$  are given in the following table.

zero	$J_0(x)$	$J_1(x)$	$J_2(x)$	$J_3(x)$	$J_4(x)$	$J_5(x)$
1	2.4048	3.8317	5.1336	6.3802	7.5883	8.7715
2	5.5201	7.0156	8.4172	9.7610	11.0647	12.3386
3	8.6537	10.1735	11.6198	13.0152	14.3725	15.7002
4	11.7915	13.3237	14.7960	16.2235	17.6160	18.9801
5	14.9309	16.4706	17.9598	19.4094	20.8269	22.2178

Let  $x_n$  be the  $n$ th ROOT of the Bessel function  $J_0(x)$ , then

$$\sum_{n=1}^{\infty} \frac{1}{x_n J_0(x_n)} = 0.38479 \dots \quad (48)$$

(Le Lionnais 1983).

The ROOTS of its DERIVATIVES are given in the following table.

zero	$J_0'(x)$	$J_1'(x)$	$J_2'(x)$	$J_3'(x)$	$J_4'(x)$	$J_5'(x)$
1	3.8317	1.8412	3.0542	4.2012	5.3175	6.4156
2	7.0156	5.3314	6.7061	8.0152	9.2824	10.5199
3	10.1735	8.5363	9.9695	11.3459	12.6819	13.9872
4	13.3237	11.7060	13.1704	14.5858	15.9641	17.3128
5	16.4706	14.8636	16.3475	17.7887	19.1960	20.5755

Various integrals can be expressed in terms of Bessel functions

$$J_0(z) = \frac{1}{2\pi} \int_0^{2\pi} e^{iz \cos \phi} d\phi \quad (49)$$

$$J_n(z) = \frac{1}{\pi} \int_0^\pi \cos(z \sin \theta - n\theta) d\theta, \quad (50)$$

which is BESSEL'S FIRST INTEGRAL,

$$J_n(z) = \frac{i^{-n}}{\pi} \int_0^\pi e^{iz \cos \theta} \cos(n\theta) d\theta \quad (51)$$

$$J_n(z) = \frac{1}{2\pi i^n} \int_0^{2\pi} e^{iz \cos \phi} e^{in\phi} d\phi \quad (52)$$

for  $n = 1, 2, \dots$ ,

$$J_n(z) = \frac{2}{\pi} \frac{x^n}{(2m-1)!!} \int_0^{\pi/2} \sin^{2n} u \cos(x \cos u) du \quad (53)$$

for  $n = 1, 2, \dots$ ,

$$J_n(x) = \frac{1}{2\pi i} \int_\gamma e^{(x/2)(z-1/z)} z^{-n-1} dz \quad (54)$$

for  $n > -1/2$ . Integrals involving  $J_1(x)$  include

$$\int_0^\infty J_1(x) dx = 1 \quad (55)$$

$$\int_0^\infty \left[ \frac{J_1(x)}{x} \right]^2 dx = \frac{4}{3\pi} \quad (56)$$

$$\int_0^\infty \left[ \frac{J_1(x)}{x} \right]^2 x dx = \frac{1}{2}. \quad (57)$$

### Bessel Function Fourier Expansion

Let  $n \geq 1/2$  and  $\alpha_1, \alpha_2, \dots$  be the POSITIVE ROOTS of  $J_n(x) = 0$ . An expansion of a function in the interval  $(0,1)$  in terms of BESSEL FUNCTIONS OF THE FIRST KIND

$$f(x) = \sum_{l=1}^{\infty} A_l J_n(x\alpha_l), \quad (1)$$

has COEFFICIENTS found as follows:

$$\int_0^1 x f(x) J_n(x\alpha_l) dx = \sum_{r=1}^{\infty} A_r \int_0^1 x J_n(x\alpha_r) J_n(x\alpha_l) dx. \quad (2)$$

But ORTHOGONALITY of BESSEL FUNCTION ROOTS gives

$$\int_0^1 x J_n(x\alpha_l) J_n(x\alpha_r) dx = \frac{1}{2} \delta_{l,r} J_{n+1}^2(\alpha_r) \quad (3)$$

(Bowman 1958, p. 108), so

$$\begin{aligned} \int_0^1 x f(x) J_n(x\alpha_l) dx &= \frac{1}{2} \sum_{r=1}^{\infty} A_r \delta_{l,r} J_{n+1}^2(x\alpha_r) \\ &= \frac{1}{2} A_l J_{n+1}^2(\alpha_l), \end{aligned} \quad (4)$$

and the COEFFICIENTS are given by

$$A_l = \frac{2}{J_{n+1}^2(\alpha_l)} \int_0^1 x f(x) J_n(x\alpha_l) dx. \quad (5)$$

### Bessel Function of the Second Kind

A Bessel function of the second kind  $Y_n(x)$  is a solution to the BESSEL DIFFERENTIAL EQUATION which is singular at the origin. Bessel functions of the second kind are also called NEUMANN FUNCTIONS or WEBER FUNCTIONS. The above plot shows  $Y_n(x)$  for  $n = 1, 2, \dots, 5$ .

Let  $v \equiv J_n(x)$  be the first solution and  $u$  be the other one (since the BESSEL DIFFERENTIAL EQUATION is second-order, there are two LINEARLY INDEPENDENT solutions). Then

$$xu'' + u' + xu = 0 \quad (1)$$

$$xv'' + v' + xv = 0. \quad (2)$$

Take  $v \times (1) - u \times (2)$ ,

$$x(u''v - uv'') + u'v - uv' = 0 \quad (3)$$

$$\frac{d}{dx}[x(u'v - uv')] = 0, \quad (4)$$

so  $x(u'v - uv') = B$ , where  $B$  is a constant. Divide by  $xv^2$ ,

$$\frac{u'v - uv'}{v^2} = \frac{d}{dx} \left( \frac{u}{v} \right) = \frac{B}{xv^2} \quad (5)$$

$$\frac{u}{v} = A + B \int \frac{dx}{xv^2}. \quad (6)$$

Rearranging and using  $v \equiv J_m(x)$  gives

$$\begin{aligned} u &= AJ_m(x) + BJ_m(x) \int \frac{dx}{xJ_m^2(x)} \\ &\equiv A'J_m(x) + B'Y_m(x), \end{aligned} \quad (7)$$

where the Bessel function of the second kind is defined by

$$\begin{aligned} Y_m(x) &= \frac{J_m(x) \cos(m\pi) - J_{-m}(x)}{\sin(m\pi)} \\ &= \frac{1}{\pi} \sum_{k=1}^{\infty} \frac{(-1)^k x^{m+2k}}{2^{m+2k} k! (m+k)!} \left[ 2 \ln \left( \frac{x}{2} \right) + 2\gamma - b_{m+k} - b_k \right] \\ &\quad - \frac{1}{\pi} \sum_{k=0}^{m-1} \frac{x^{-m+2k} (m-k-1)!}{2^{-m+2k} k!} \end{aligned} \quad (8)$$

$m = 0, 1, 2, \dots$ ,  $\gamma$  is the EULER-MASCHERONI CONSTANT, and

$$b_k \equiv \begin{cases} 0 & k = 0, \\ \sum_{n=0}^k \frac{1}{n} & k \neq 0. \end{cases} \quad (9)$$

The function is given by

$$\begin{aligned} Y_n(z) &= \frac{1}{\pi} \int_0^\pi \sin(z \sin \theta - n\theta) d\theta \\ &\quad - \frac{1}{\pi} \int_0^\infty [e^{nt} + e^{-nt} (-1)^n] e^{-z \sinh t} dt. \end{aligned} \quad (10)$$

Asymptotic equations are

$$Y_m(x) = \begin{cases} \frac{2}{\pi} \left[ \ln \left( \frac{1}{2} x \right) + \gamma \right] & m = 0, x \ll 1 \\ -\frac{\Gamma(m)}{\pi} \left( \frac{2}{x} \right)^m & m \neq 0, x \ll 1 \end{cases} \quad (11)$$

$$Y_m(x) = \sqrt{\frac{2}{\pi x}} \sin \left( x - \frac{m\pi}{2} - \frac{\pi}{4} \right) \quad x \gg 1, \quad (12)$$

where  $\Gamma(z)$  is a GAMMA FUNCTION.

#### Bessel Function of the Third Kind

see HANKEL FUNCTION

#### Bessel's Inequality

If  $f(x)$  is piecewise CONTINUOUS and has a general FOURIER SERIES

$$\sum_i a_i \phi_i(x) \quad (1)$$

with WEIGHTING FUNCTION  $w(x)$ , it must be true that

$$\int \left[ f(x) - \sum_i a_i \phi_i(x) \right]^2 w(x) dx \geq 0 \quad (2)$$

$$\begin{aligned} \int f^2(x) w(x) dx - 2 \sum_i a_i \int f(x) \phi_i(x) w(x) dx \\ + \sum_i a_i^2 \int \phi_i^2(x) w(x) dx \geq 0. \end{aligned} \quad (3)$$

But the COEFFICIENT of the generalized FOURIER SERIES is given by

$$a_m \equiv \int f(x) \phi_m(x) w(x) dx, \quad (4)$$

so

$$\int f^2(x) w(x) dx - 2 \sum_i a_i^2 + \sum_i a_i^2 \geq 0 \quad (5)$$

$$\int f^2(x) w(x) dx \geq \sum_i a_i^2. \quad (6)$$

Equation (6) is an inequality if the functions  $\phi_i$  are not COMPLETE. If they are COMPLETE, then the inequality (2) becomes an equality, so (6) becomes an equality and is known as PARSEVAL'S THEOREM. If  $f(x)$  has a simple FOURIER SERIES expansion with COEFFICIENTS  $a_0, a_1, \dots, a_n$  and  $b_1, \dots, b_n$ , then

$$\frac{1}{2} a_0^2 + \sum_{k=1}^{\infty} (a_k^2 + b_k^2) \leq \frac{1}{\pi} \int_{-\pi}^{\pi} [f(x)]^2 dx. \quad (7)$$

The inequality can also be derived from SCHWARZ'S INEQUALITY

$$|\langle f|g \rangle|^2 \leq \langle f|f \rangle \langle g|g \rangle \quad (8)$$

by expanding  $g$  in a superposition of EIGENFUNCTIONS of  $f$ ,  $g = \sum_i a_i f_i$ . Then

$$\langle f|g \rangle = \sum_i a_i \langle f|f_i \rangle \leq \sum_i a_i \quad (9)$$

$$\begin{aligned} |\langle f|g \rangle|^2 &\leq \left| \sum_i a_i \right|^2 = \left( \sum_i a_i \right) \left( \sum_i a_i^* \right) \\ &= \sum_i a_i a_i^* \leq \langle f|f \rangle \langle g|g \rangle. \end{aligned} \quad (10)$$

If  $g$  is normalized, then  $\langle g|g \rangle = 1$  and

$$\langle f|f \rangle \geq \sum_i a_i a_i^*. \quad (11)$$

see also SCHWARZ'S INEQUALITY, TRIANGLE INEQUALITY

$$t = \frac{\bar{w} - \omega}{\sigma_w / \sqrt{N}} = \frac{\bar{w} - \omega}{\sqrt{\frac{\sum_{i=1}^N (w_i - \bar{w})^2}{N(N-1)}}}, \quad (1)$$

where

$$\bar{w} \equiv \hat{x}_1 - \bar{x}_2 \quad (2)$$

$$\omega \equiv \mu_{(1)} - \mu_{(2)} \quad (3)$$

$$N \equiv N_1 + N_2. \quad (4)$$

### Beta

A financial measure of a fund's sensitivity to market movements which measures the relationship between a fund's excess return over Treasury Bills and the excess return of a benchmark index (which, by definition, has  $\beta = 1$ ). A fund with a beta of  $\beta$  has performed  $r = (\beta - 1) \times 100\%$  better (or  $|r|$  worse if  $r < 0$ ) than its benchmark index (after deducting the T-bill rate) in up markets and  $|r|$  worse (or  $|r|$  better if  $r < 0$ ) in down markets.

see also ALPHA, SHARPE RATIO

### Beta Distribution

A general type of statistical DISTRIBUTION which is related to the GAMMA DISTRIBUTION. Beta distributions have two free parameters, which are labeled according to one of two notational conventions. The usual definition calls these  $\alpha$  and  $\beta$ , and the other uses  $\beta' \equiv \beta - 1$  and  $\alpha' \equiv \alpha - 1$  (Beyer 1987, p. 534). The above plots are for  $(\alpha, \beta) = (1, 1)$  [solid],  $(1, 2)$  [dotted], and  $(2, 3)$  [dashed]. The probability function  $P(x)$  and DISTRIBUTION FUNCTION  $D(x)$  are given by

$$\begin{aligned} P(x) &= \frac{(1-x)^{\beta-1} x^{\alpha-1}}{B(\alpha, \beta)} \\ &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} (1-x)^{\beta-1} x^{\alpha-1} \end{aligned} \quad (1)$$

$$D(x) = I(x; a, b), \quad (2)$$

where  $B(a, b)$  is the BETA FUNCTION,  $I(x; a, b)$  is the REGULARIZED BETA FUNCTION, and  $0 < x < 1$  where  $\alpha, \beta > 0$ . The distribution is normalized since

$$\begin{aligned} \int_0^1 P(x) dx &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} \int_0^1 x^{\alpha-1} (1-x)^{\beta-1} dx \\ &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} B(\alpha, \beta) = 1. \end{aligned} \quad (3)$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = {}_1F_1(a, a + b, it). \quad (4)$$

The MOMENTS are given by

$$M_r = \int_0^1 (x - \mu)^r dx = \frac{\Gamma(\alpha + \beta)\Gamma(\alpha + r)}{\Gamma(\alpha + \beta + r)\Gamma(\alpha)}. \quad (5)$$

The MEAN is

$$\begin{aligned} \mu &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} \int_0^1 x^{\alpha-1} (1-x)^{\beta-1} x dx \\ &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} B(\alpha + 1, \beta) \\ &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} \frac{\Gamma(\alpha + 1)\Gamma(\beta)}{\Gamma(\alpha + \beta + 1)} = \frac{\alpha}{\alpha + \beta}, \end{aligned} \quad (6)$$

and the VARIANCE, SKEWNESS, and KURTOSIS are

$$\sigma^2 = \frac{\alpha\beta}{(\alpha + \beta)^2(\alpha + \beta + 1)} \quad (7)$$

$$\gamma_1 = \frac{2(\sqrt{\beta} - \sqrt{\alpha})(\sqrt{\alpha} + \sqrt{\beta})\sqrt{1 + \alpha + \beta}}{\sqrt{\alpha\beta}(\alpha + \beta + 2)} \quad (8)$$

$$\gamma_2 = \frac{6(\alpha^2 + \alpha^3 - 4\alpha\beta - 2\alpha^2\beta + \beta^2 - 2\alpha\beta^2 + \beta^3)}{\alpha\beta(\alpha + \beta + 2)(\alpha + \beta + 3)}. \quad (9)$$

The MODE of a variate distributed as  $\beta(\alpha, \beta)$  is

$$\hat{x} = \frac{\alpha - 1}{\alpha + \beta - 2}. \quad (10)$$

In "normal" form, the distribution is written

$$f(x) = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1} (1-x)^{\beta-1} \quad (11)$$

and the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \frac{\alpha}{\alpha + \beta} \quad (12)$$

$$\sigma^2 = \frac{\alpha\beta}{(\alpha + \beta)^2(1 + \alpha + \beta)} \quad (13)$$

$$\gamma_1 = \frac{2(\sqrt{\alpha} - \sqrt{\beta})(\sqrt{\alpha} + \sqrt{\beta})\sqrt{1 + \alpha + \beta}}{\sqrt{\alpha\beta}(\alpha + \beta + 2)} \quad (14)$$

$$\gamma_2 = \frac{3(1 + \alpha + \beta)(2\alpha^2 - 2\alpha\beta + \alpha^2\beta + 2\beta^2 + \alpha\beta^2)}{\alpha\beta(\alpha + \beta + 2)(\alpha + \beta + 3)} \quad (15)$$

see also GAMMA DISTRIBUTION

### Beta Function

The beta function is the name used by Legendre and Whittaker and Watson (1990) for the EULERIAN INTEGRAL OF THE SECOND KIND. To derive the integral representation of the beta function, write the product of two FACTORIALS as

$$m!n! = \int_0^\infty e^{-u} u^m du \int_0^\infty e^{-v} v^n dv. \quad (1)$$

Now, let  $u \equiv x^2$ ,  $v \equiv y^2$ , so

$$\begin{aligned} m!n! &= 4 \int_0^\infty e^{-x^2} x^{2m+1} dx \int_0^\infty e^{-y^2} y^{2n+1} dy \\ &= 4 \int_{-\infty}^\infty \int_{-\infty}^\infty e^{-(x^2+y^2)} x^{2m+1} y^{2n+1} dx dy. \end{aligned} \quad (2)$$

Transforming to POLAR COORDINATES with  $x = r \cos \theta$ ,  $y = r \sin \theta$

$$\begin{aligned} m!n! &= 4 \int_0^{\pi/2} \int_0^\infty e^{-r^2} (r \cos \theta)^{2m+1} (r \sin \theta)^{2n+1} r dr d\theta \\ &= 4 \int_0^\infty e^{-r^2} r^{2m+2n+3} dr \int_0^{\pi/2} \cos^{2m+1} \theta \sin^{2n+1} \theta d\theta \\ &= 2(m+n+1)! \int_0^{\pi/2} \cos^{2m+1} \theta \sin^{2n+1} \theta d\theta. \end{aligned} \quad (3)$$

The beta function is then defined by

$$\begin{aligned} B(m+1, n+1) &= B(n+1, m+1) \\ &\equiv 2 \int_0^{\pi/2} \cos^{2m+1} \theta \sin^{2n+1} \theta d\theta = \frac{m!n!}{(m+n+1)!}. \end{aligned} \quad (4)$$

Rewriting the arguments,

$$B(p, q) = \frac{\Gamma(p)\Gamma(q)}{\Gamma(p+q)} = \frac{(p-1)!(q-1)!}{(p+q-1)!}. \quad (5)$$

The general trigonometric form is

$$\int_0^{\pi/2} \sin^n x \cos^m x dx = \frac{1}{2} B(n + \frac{1}{2}, m + \frac{1}{2}). \quad (6)$$

Equation (6) can be transformed to an integral over POLYNOMIALS by letting  $u \equiv \cos^2 \theta$ ,

$$B(m+1, n+1) \equiv \frac{m!n!}{(m+n+1)!} = \int_0^1 u^m (1-u)^n du \quad (7)$$

$$B(m, n) \equiv \frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n)} = \int_0^1 u^{m-1} (1-u)^{n-1} du. \quad (8)$$

To put it in a form which can be used to derive the LEGENDRE DUPLICATION FORMULA, let  $x \equiv \sqrt{u}$ , so  $u = x^2$  and  $du = 2x dx$ , and

$$\begin{aligned} B(m, n) &= \int_0^1 x^{2(m-1)} (1-x^2)^{n-1} (2x dx) \\ &= 2 \int_0^1 x^{2m-1} (1-x^2)^{n-1} dx. \end{aligned} \quad (9)$$

To put it in a form which can be used to develop integral representations of the BESSEL FUNCTIONS and HYPERGEOMETRIC FUNCTION, let  $u \equiv x/(1+x)$ , so

$$B(m+1, n+1) = \int_0^\infty \frac{u^m du}{(1+u)^{m+n+2}}. \quad (10)$$

Various identities can be derived using the GAUSS MULTIPLICATION FORMULA

$$\begin{aligned} B(np, nq) &= \frac{\Gamma(np)\Gamma(nq)}{\Gamma[n(p+q)]} \\ &= n^{-nq} \frac{B(p, q)B(p + \frac{1}{n}, q) \cdots B(p + \frac{n-1}{n}, q)}{B(q, q)B(2q, q) \cdots B([n-1]q, q)}. \end{aligned} \quad (11)$$

Additional identities include

$$\begin{aligned} B(p, q+1) &= \frac{\Gamma(p)\Gamma(q+1)}{\Gamma(p+q+1)} = \frac{q}{p} \frac{\Gamma(p+1)\Gamma(q)}{\Gamma([p+1]q)} \\ &= \frac{q}{p} B(p+1, q) \end{aligned} \quad (12)$$

$$B(p, q) = B(p+1, q) + B(p, q+1) \quad (13)$$

$$B(p, q+1) = \frac{q}{p+q} B(p, q). \quad (14)$$

If  $n$  is a POSITIVE INTEGER, then

$$B(p, n+1) = \frac{1 \cdot 2 \cdots n}{p(p+1) \cdots (p+n)} \quad (15)$$

$$B(p, p) B(p + \frac{1}{2}, p + \frac{1}{2}) = \frac{\pi}{2^{4p-1} p} \quad (16)$$

$$B(p+q) B(p+q, r) = B(q, r) B(q+r, p). \quad (17)$$

A generalization of the beta function is the incomplete beta function

$$\begin{aligned} B(t; x, y) &\equiv \int_0^t u^{x-1} (1-u)^{y-1} du \\ &= t^p \left[ \frac{1}{x} + \frac{1-y}{x+1} t + \dots + \frac{(1-y) \cdots (n-y)}{n!(x+n)} t^n + \dots \right]. \end{aligned} \quad (18)$$

#### Beta Function (Exponential)

Another "BETA FUNCTION" defined in terms of an integral is the "exponential" beta function, given by

$$\begin{aligned} \beta_n(z) &\equiv \int_{-1}^1 t^n e^{-zt} dt \\ &= n! z^{-(n+1)} \left[ e^z \sum_{k=0}^n \frac{(-1)^k z^k}{k!} - e^{-z} \sum_{k=0}^n \frac{z^k}{k!} \right]. \end{aligned} \quad (1)$$

$$(2)$$

The exponential beta function satisfies the RECURRENCE RELATION

$$z\beta_n(z) = (-1)^n e^z - e^{-z} + n\beta_{n-1}(z). \quad (3)$$

The first few integral values are

$$\beta_0(z) = \frac{2 \sinh z}{z} \quad (4)$$

$$\beta_1(z) = \frac{2(\sinh z - z \cosh z)}{z^2} \quad (5)$$

$$\beta_2(z) = \frac{2(2 + z^2) \sinh z - 4z \cosh z}{z^3}. \quad (6)$$

see also ALPHA FUNCTION

#### Beta Prime Distribution

A distribution with probability function

$$P(x) = \frac{x^{\alpha-1} (1+x)^{-\alpha-\beta}}{B(\alpha, \beta)},$$

where  $B$  is a BETA FUNCTION. The MODE of a variate distributed as  $\beta'(\alpha, \beta)$  is

$$\hat{x} = \frac{\alpha - 1}{\beta + 1}.$$

If  $x$  is a  $\beta'(\alpha, \beta)$  variate, then  $1/x$  is a  $\beta'(\beta, \alpha)$  variate. If  $x$  is a  $\beta(\alpha, \beta)$  variate, then  $(1-x)/x$  and  $x/(1-x)$  are  $\beta'(\beta, \alpha)$  and  $\beta'(\alpha, \beta)$  variates. If  $x$  and  $y$  are  $\gamma(\alpha_1)$  and  $\gamma(\alpha_2)$  variates, then  $x/y$  is a  $\beta'(\alpha_1, \alpha_2)$  variate. If  $x^2/2$  and  $y^2/2$  are  $\gamma(1/2)$  variates, then  $z^2 \equiv (x/y)^2$  is a  $\beta'(1/2, 1/2)$  variate.

#### Bethe Lattice

see CAYLEY TREE

#### Betrothed Numbers

see QUASIAMICABLE PAIR

#### Betti Group

The free part of the HOMOLOGY GROUP with a domain of COEFFICIENTS in the GROUP of INTEGERS (if this HOMOLOGY GROUP is finitely generated).

#### References

## Betti Number

Betti numbers are topological objects which were proved to be invariants by Poincaré, and used by him to extend the POLYHEDRAL FORMULA to higher dimensional spaces. The  $n$ th Betti number is the rank of the  $n$ th HOMOLOGY GROUP. Let  $p_r$  be the RANK of the HOMOLOGY GROUP  $H_r$  of a TOPOLOGICAL SPACE  $K$ . For a closed, orientable surface of GENUS  $g$ , the Betti numbers are  $p_0 = 1$ ,  $p_1 = 2g$ , and  $p_2 = 1$ . For a nonorientable surface with  $k$  CROSS-CAPS, the Betti numbers are  $p_0 = 1$ ,  $p_1 = k - 1$ , and  $p_2 = 0$ .

see also EULER CHARACTERISTIC, POINCARÉ DUALITY

## Bézier Curve

Given a set of  $n$  control points, the corresponding Bézier curve (or BERNSTEIN-BÉZIER CURVE) is given by

$$C(t) = \sum_{i=0}^n P_i B_{i,n}(t),$$

where  $B_{i,n}(t)$  is a BERNSTEIN POLYNOMIAL and  $t \in [0, 1]$ .

A "rational" Bézier curve is defined by

$$C(t) = \frac{\sum_{i=0}^n B_{i,p}(t) w_i P_i}{\sum_{i=0}^n B_{i,p}(t) w_i},$$

where  $p$  is the order,  $B_{i,p}$  are the BERNSTEIN POLYNOMIALS,  $P_i$  are control points, and the weight  $w_i$  of  $P_i$  is the last ordinate of the homogeneous point  $P_i^w$ . These curves are closed under perspective transformations, and can represent CONIC SECTIONS exactly.

The Bézier curve always passes through the first and last control points and lies within the CONVEX HULL of the control points. The curve is tangent to  $P_1 - P_0$  and  $P_n - P_{n-1}$  at the endpoints. The "variation diminishing property" of these curves is that no line can have more intersections with a Bézier curve than with the curve obtained by joining consecutive points with straight line segments. A desirable property of these curves is that the curve can be translated and rotated by performing these operations on the control points.

Undesirable properties of Bézier curves are their numerical instability for large numbers of control points, and

the fact that moving a single control point changes the global shape of the curve. The former is sometimes avoided by smoothly patching together low-order Bézier curves. A generalization of the Bézier curve is the B-SPLINE.

see also B-SPLINE, NURBS CURVE

## Bézier Spline

see BÉZIER CURVE, SPLINE

## Bezout Numbers

Integers  $(\lambda, \mu)$  for  $a$  and  $b$  such that

$$\lambda a + \mu b = \text{GCD}(a, b).$$

For INTEGERS  $a_1, \dots, a_n$ , the Bezout numbers are a set of numbers  $k_1, \dots, k_n$  such that

$$k_1 a_1 + k_2 a_2 + \dots + k_n a_n = d,$$

where  $d$  is the GREATEST COMMON DIVISOR of  $a_1, \dots, a_n$ .

see also GREATEST COMMON DIVISOR

## Bezout's Theorem

In general, two algebraic curves of degrees  $m$  and  $n$  intersect in  $m \cdot n$  points and cannot meet in more than  $m \cdot n$  points unless they have a component in common (i.e., the equations defining them have a common factor). This can also be stated: if  $P$  and  $Q$  are two POLYNOMIALS with no roots in common, then there exist two other POLYNOMIALS  $A$  and  $B$  such that  $AP + BQ = 1$ . Similarly, given  $N$  POLYNOMIAL equations of degrees  $n_1, n_2, \dots, n_N$  in  $N$  variables, there are in general  $n_1 n_2 \dots n_N$  common solutions.

see also POLYNOMIAL

## Bhargava's Theorem

Let the  $n$ th composition of a function  $f(x)$  be denoted  $f^{(n)}(x)$ , such that  $f^{(0)}(x) = x$  and  $f^{(1)}(x) = f(x)$ . Denote  $f \circ g(x) = f(g(x))$ , and define

$$\sum F(a, b, c) = F(a, b, c) + F(b, c, a) + F(c, a, b). \quad (1)$$

Let

$$u \equiv (a, b, c) \quad (2)$$

$$|u| \equiv a + b + c \quad (3)$$

$$||u|| \equiv a^4 + b^4 + c^4, \quad (4)$$

and

$$f(u) = (f_1(u), f_2(u), f_3(u)) \quad (5)$$

$$= (a(b-c), b(c-a), c(a-b)) \quad (6)$$

$$g(u) = (g_1(u), g_2(u), g_3(u)) \\ = \left( \sum a^2 b, \sum ab^2, 3abc \right). \quad (7)$$

Then if  $|u| = 0$ ,

$$\|f^{(m)} \circ g^{(n)}(u)\| = 2(ab + bc + ca)^{2^{m+1}3^n} \\ = \|g^{(n)} \circ f^{(m)}(u)\|, \quad (8)$$

where  $m, n \in \{0, 1, \dots\}$  and composition is done in terms of components.

### Bhaskara-Brouckner Algorithm

see SQUARE ROOT

### Bi-Connected Component

A maximal SUBGRAPH of an undirected graph such that any two edges in the SUBGRAPH lie on a common simple cycle.

see also STRONGLY CONNECTED COMPONENT

### Bianchi Identities

The RIEMANN TENSOR is defined by

$$R_{\lambda\mu\nu\kappa;\eta} = \frac{1}{2} \frac{\partial}{\partial x^\eta} \left( \frac{\partial^2 g_{\lambda\nu}}{\partial x^\kappa \partial x^\mu} - \frac{\partial^2 g_{\mu\nu}}{\partial x^\kappa \partial x^\lambda} - \frac{\partial^2 g_{\lambda\kappa}}{\partial x^\mu \partial x^\nu} + \frac{\partial^2 g_{\mu\kappa}}{\partial x^\nu \partial x^\lambda} \right).$$

Permuting  $\nu$ ,  $\kappa$ , and  $\eta$  (Weinberg 1972, pp. 146–147) gives the Bianchi identities

$$R_{\lambda\mu\nu\kappa;\eta} + R_{\lambda\mu\eta\nu;\kappa} + R_{\lambda\mu\kappa\eta;\nu} = 0.$$

see also BIANCHI IDENTITIES (CONTRACTED), RIEMANN TENSOR

#### References

- Weinberg, S. *Gravitation and Cosmology: Principles and Applications of the General Theory of Relativity*. New York: Wiley, 1972.

### Bianchi Identities (Contracted)

CONTRACTING  $\lambda$  with  $\nu$  in the BIANCHI IDENTITIES

$$R_{\lambda\mu\nu\kappa;\eta} + R_{\lambda\mu\eta\nu;\kappa} + R_{\lambda\mu\kappa\eta;\nu} = 0 \quad (1)$$

gives

$$R_{\mu\kappa;\eta} - R_{\mu\eta;\kappa} + R^\nu_{\mu\kappa\eta;\nu} = 0. \quad (2)$$

CONTRACTING again,

$$R_{;\eta} - R^\mu_{\eta;\mu} - R^\nu_{\eta;\nu} = 0, \quad (3)$$

or

$$(R^\mu_{\eta} - \frac{1}{2}\delta^\mu_{\eta} R)_{;\mu} = 0, \quad (4)$$

or

$$(R^{\mu\nu} - \frac{1}{2}g^{\mu\nu} R)_{;\mu} = 0. \quad (5)$$

### Bias (Estimator)

The bias of an ESTIMATOR  $\tilde{\theta}$  is defined as

$$B(\tilde{\theta}) \equiv \langle \tilde{\theta} \rangle - \theta.$$

It is therefore true that

$$\tilde{\theta} - \theta = (\tilde{\theta} - \langle \tilde{\theta} \rangle) + (\langle \tilde{\theta} \rangle - \theta) = (\tilde{\theta} - \langle \tilde{\theta} \rangle) + B(\tilde{\theta}).$$

An ESTIMATOR for which  $B = 0$  is said to be UNBIASED.

see also ESTIMATOR, UNBIASED

### Bias (Series)

The bias of a SERIES is defined as

$$Q[a_i, a_{i+1}, a_{i+2}] \equiv \frac{a_i a_{i+2} - a_{i+1}^2}{a_i a_{i+1} a_{i+2}}.$$

A SERIES is GEOMETRIC IFF  $Q = 0$ . A SERIES is ARTISTIC IFF the bias is constant.

see also ARTISTIC SERIES, GEOMETRIC SERIES

see BLOCK DESIGN

### Bicentric Polygon

A POLYGON which has both a CIRCUMCIRCLE and an INCIRCLE, both of which touch all VERTICES. All TRIANGLES are bicentric with

$$R^2 - s^2 = 2Rr, \quad (1)$$

where  $R$  is the CIRCUMRADIUS,  $r$  is the INRADIUS, and  $s$  is the separation of centers. In 1798, N. Fuss characterized bicentric POLYGONS of  $n = 4, 5, 6, 7$ , and 8 sides. For bicentric QUADRILATERALS (FUSS'S PROBLEM), the CIRCLES satisfy

$$2r^2(R^2 - s^2) = (R^2 - s^2)^2 - 4r^2s^2 \quad (2)$$

(Dörrie 1965) and

$$r = \frac{\sqrt{abcd}}{s} \quad (3)$$

$$R = \frac{1}{4} \sqrt{\frac{(ac + bd)(ad + bc)(ab + cd)}{abcd}} \quad (4)$$

(Beyer 1987). In addition,

$$\frac{1}{(R - s)^2} + \frac{1}{(R + s)^2} = \frac{1}{r^2} \quad (5)$$

and

$$a + c = b + d. \quad (6)$$

The AREA of a bicentric quadrilateral is

$$A = \sqrt{abcd}. \quad (7)$$

If the circles permit successive tangents around the INCIRCLE which close the POLYGON for one starting point on the CIRCUMCIRCLE, then they do so for all points on the CIRCUMCIRCLE.

### Bicorn

The bicorn is the name of a collection of QUARTIC CURVES studied by SYLVESTER in 1864 and CAYLEY in 1867 (MacTutor Archive). The bicorn is given by the parametric equations

$$\begin{aligned} x &= a \sin t \\ y &= \frac{a \cos^2 t (2 + \cos t)}{3 \sin^2 t}. \end{aligned}$$

The graph is similar to that of the COCKED HAT CURVE.

**Bicubic Spline**

A bicubic spline is a special case of bicubic interpolation which uses an interpolation function of the form

$$y(x_1, x_2) = \sum_{i=1}^4 \sum_{j=1}^4 c_{ij} t^{i-1} u^{j-1}$$

$$y_{x_1}(x_1, x_2) = \sum_{i=1}^4 \sum_{j=1}^4 (i-1) c_{ij} t^{i-2} u^{j-1}$$

$$y_{x_2}(x_1, x_2) = \sum_{i=1}^4 \sum_{j=1}^4 (j-1) c_{ij} t^{i-1} u^{j-2}$$

$$y_{x_1 x_2} = \sum_{i=1}^4 \sum_{j=1}^4 (i-1)(j-1) c_{ij} t^{i-2} u^{j-2},$$

where  $c_{ij}$  are constants and  $u$  and  $t$  are parameters ranging from 0 to 1. For a bicubic spline, however, the partial derivatives at the grid points are determined globally by 1-D SPLINES.

The PLANE CURVE given by the Cartesian equation

$$(x^2 - a^2)(x - a)^2 + (y^2 - a^2)^2 = 0.$$

**Bicylinder**

see STEINMETZ SOLID

**Bidiakis Cube**

The 12-VERTEX graph consisting of a CUBE in which two opposite faces (say, top and bottom) have edges drawn across them which connect the centers of opposite sides of the faces in such a way that the orientation of the edges added on top and bottom are PERPENDICULAR to each other.

see also BISLIT CUBE, CUBE, CUBICAL GRAPH

**Bieberbach Conjecture**

The  $n$ th COEFFICIENT in the POWER series of a UNIVALENT FUNCTION should be no greater than  $n$ . In other words, if

$$f(z) = a_0 + a_1 z + a_2 z^2 + \dots + a_n z^n + \dots$$

is a conformal transformation of a unit disk on any domain, then  $|a_n| \leq n|a_1|$ . In more technical terms, “geometric extremality implies metric extremality.” The conjecture had been proven for the first six terms (the cases  $n = 2, 3$ , and  $4$  were done by Bieberbach, Lowner, and Shiffer and Garbedjian, respectively), was known to be false for only a finite number of indices (Hayman 1954), and true for a convex or symmetric domain (Le Lionnais 1983). The general case was proved by Louis de Branges (1985). De Branges proved the MILIN CONJECTURE, which established the ROBERTSON CONJECTURE, which in turn established the Bieberbach conjecture (Stewart 1996).

## Biharmonic Equation

The differential equation obtained by applying the BIHARMONIC OPERATOR and setting to zero.

$$\nabla^4 \phi = 0. \quad (1)$$

In CARTESIAN COORDINATES, the biharmonic equation is

$$\begin{aligned} \nabla^4 \phi &= \nabla^2(\nabla^2)\phi \\ &= \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) \phi \\ &= \frac{\partial^4 \phi}{\partial x^4} + \frac{\partial^4 \phi}{\partial y^4} + \frac{\partial^4 \phi}{\partial z^4} + 2 \frac{\partial^4 \phi}{\partial x^2 \partial y^2} \\ &\quad + 2 \frac{\partial^4 \phi}{\partial y^2 \partial z^2} + 2 \frac{\partial^4 \phi}{\partial x^2 \partial z^2} = 0. \end{aligned} \quad (2)$$

In POLAR COORDINATES (Kaplan 1984, p. 148)

$$\begin{aligned} \nabla^4 \phi &= \phi_{rrrr} + \frac{2}{r^2} \phi_{rr\theta\theta} + \frac{1}{r^4} \phi_{\theta\theta\theta\theta} + \frac{2}{r} \phi_{rrr} \\ &\quad - \frac{2}{r^3} \phi_{r\theta\theta} - \frac{1}{r^2} \phi_{rr} + \frac{4}{r^4} \phi_{\theta\theta} + \frac{1}{r^3} \phi_r = 0. \end{aligned} \quad (3)$$

For a radial function  $\phi(r)$ , the biharmonic equation becomes

$$\begin{aligned}\nabla^4 \phi &= \frac{1}{r} \frac{d}{dr} \left\{ r \frac{d}{dr} \left[ \frac{1}{r} \frac{d}{dr} \left( r \frac{d\phi}{dr} \right) \right] \right\} \\ &= \phi_{rrrr} + \frac{2}{r} \phi_{rrr} - \frac{1}{r^2} \phi_{rr} + \frac{1}{r^3} \phi_r = 0.\end{aligned}\quad (4)$$

Writing the inhomogeneous equation as

$$\nabla^4 \phi = 64\beta, \quad (5)$$

we have

$$64\beta r \, dr = d \left\{ r \frac{d}{dr} \left[ \frac{1}{r} \frac{d}{dr} \left( r \frac{d\phi}{dr} \right) \right] \right\} \quad (6)$$

$$32\beta r^2 + C_1 = r \frac{d}{dr} \left[ \frac{1}{r} \frac{d}{dr} \left( r \frac{d\phi}{dr} \right) \right] \quad (7)$$

$$\left( 32\beta r + \frac{C_1}{r} \right) dr = d \left[ \frac{1}{r} \frac{d}{dr} \left( r \frac{d\phi}{dr} \right) \right] \quad (8)$$

$$16\beta r^2 + C_1 \ln r + C_2 = \frac{1}{r} \frac{d}{dr} \left( r \frac{d\phi}{dr} \right) \quad (9)$$

$$(16\beta r^3 + C_1 r \ln r + C_2 r) dr = d \left( r \frac{d\phi}{dr} \right). \quad (10)$$

Now use

$$\int r \ln r \, dr = \frac{1}{2} r^2 \ln r - \frac{1}{4} r^2 \quad (11)$$

to obtain

$$4\beta r^4 + C_1 \left( \frac{1}{2} r^2 \ln r - \frac{1}{4} r^2 \right) + \frac{1}{2} C_2 r^2 + C_3 = r \frac{d\phi}{dr} \quad (12)$$

$$\left( 4\beta r^3 + C_1' r \ln r + C_2' r + \frac{C_3}{r} \right) dr = d\phi \quad (13)$$

$$\begin{aligned}\phi(r) &= \beta r^4 + C_1' \left( \frac{1}{2} r^2 \ln r - \frac{1}{4} r^2 \right) \\ &\quad + \frac{1}{2} C_2' r^2 + C_3 \ln r + C_4 \\ &= \beta r^4 + ar^2 + b + (cr^2 + d) \ln \left( \frac{r}{R} \right).\end{aligned}\quad (14)$$

The homogeneous biharmonic equation can be separated and solved in 2-D BIPOLAR COORDINATES.

### Biharmonic Operator

Also known as the BILAPLACIAN.

$$\nabla^4 \equiv (\nabla^2)^2.$$

In  $n$ -D space,

$$\nabla^4 \left( \frac{1}{r} \right) = \frac{3(15 - 8n + n^2)}{r^5}.$$

see also BIHARMONIC EQUATION

### Bijection

A transformation which is ONE-TO-ONE and ONTO.

see also ONE-TO-ONE, ONTO, PERMUTATION

### Bilaplacian

see BIHARMONIC OPERATOR

### Bilinear

A function of two variables is bilinear if it is linear with respect to each of its variables. The simplest example is  $f(x, y) = xy$ .

### Bilinear Basis

A bilinear basis is a BASIS, which satisfies the conditions

$$(a\mathbf{x} + b\mathbf{y}) \cdot \mathbf{z} = a(\mathbf{x} \cdot \mathbf{z}) + b(\mathbf{y} \cdot \mathbf{z})$$

$$\mathbf{z} \cdot (a\mathbf{x} + b\mathbf{y}) = a(\mathbf{z} \cdot \mathbf{x}) + b(\mathbf{z} \cdot \mathbf{y}).$$

see also BASIS

### Billiard Table Problem

Given a billiard table with only corner pockets and sides of INTEGER lengths  $m$  and  $n$ , a ball sent at a  $45^\circ$  angle from a corner will be pocketed in a corner after  $m+n-2$  bounces.

see also ALHAZEN'S BILLIARD PROBLEM, BILLIARDS

### Billiards

The game of billiards is played on a RECTANGULAR table (known as a billiard table) upon which balls are placed. One ball (the "cue ball") is then struck with the end of a "cue" stick, causing it to bounce into other balls and REFLECT off the sides of the table. Real billiards can involve spinning the ball so that it does not travel in a straight LINE, but the mathematical study of billiards generally consists of REFLECTIONS in which the reflection and incidence angles are the same. However, strange table shapes such as CIRCLES and ELLIPSES are often considered. Many interesting problems can arise.

For example, ALHAZEN'S BILLIARD PROBLEM seeks to find the point at the edge of a circular "billiards" table at which a cue ball at a given point must be aimed in order to carom once off the edge of the table and strike another ball at a second given point. It was not until 1997 that Neumann proved that the problem is insoluble using a COMPASS and RULER construction.

On an ELLIPTICAL billiard table, the ENVELOPE of a trajectory is a smaller ELLIPSE, a HYPERBOLA, a LINE through the FOCI of the ELLIPSE, or periodic curve (e.g., DIAMOND-shape) (Wagon 1991).

see also ALHAZEN'S BILLIARD PROBLEM, BILLIARD TABLE PROBLEM, REFLECTION PROPERTY

### Bimodal Distribution

A DISTRIBUTION having two separated peaks.

see also UNIMODAL DISTRIBUTION

### Bimonster

The wreathed product of the MONSTER GROUP by  $Z_2$ . The bimonster is a quotient of the COXETER GROUP with the following COXETER-DYNKIN DIAGRAM.

This had been conjectured by Conway, but was proven around 1990 by Ivanov and Norton. If the parameters  $p, q, r$  in Coxeter's NOTATION  $[3^p, q, r]$  are written side by side, the bimonster can be denoted by the BEAST NUMBER 666.

### Bin

An interval into which a given data point does or does not fall.

see also HISTOGRAM

### Binary

The BASE 2 method of counting in which only the digits 0 and 1 are used. In this BASE, the number 1011 equals  $1 \cdot 2^3 + 0 \cdot 2^2 + 1 \cdot 2^1 + 1 \cdot 2^0 = 11$ . This BASE is used in computers, since all numbers can be simply represented as a string of electrically pulsed ons and offs. A NEGATIVE  $-n$  is most commonly represented as the complement of the POSITIVE number  $n - 1$ , so  $-11 = 00001011_2$  would be written as the complement of  $10 = 00001010_2$ , or 11110101. This allows addition to be carried out with the usual carrying and the left-most digit discarded, so  $17 - 11 = 6$  gives

$$\begin{array}{r} 00010001 \quad 17 \\ 11110101 \quad -11 \\ \hline 00000110 \quad 6 \end{array}$$

The number of times  $k$  a given binary number  $b_n \dots b_2 b_1 b_0$  is divisible by 2 is given by the position of the first  $b_k = 1$  counting from the right. For example,  $12 = 1100$  is divisible by 2 twice, and  $13 = 1101$  is divisible by 2 0 times.

Unfortunately, the storage of binary numbers in computers is not entirely standardized. Because computers store information in 8-bit bytes (where a bit is a single binary digit), depending on the "word size" of the machine, numbers requiring more than 8 bits must be stored in multiple bytes. The usual FORTRAN77 integer size is 4 bytes long. However, a number represented as (byte1 byte2 byte3 byte4) in a VAX would be read and interpreted as (byte4 byte3 byte2 byte1) on a Sun. The situation is even worse for floating point (real) numbers, which are represented in binary as a MANTISSA and CHARACTERISTIC, and worse still for long (8-byte) reals!

Binary multiplication of single bit numbers (0 or 1) is equivalent to the AND operation, as can be seen in the following MULTIPLICATION TABLE.

$\times$	0	1
0	0	0
1	0	1

### Binary Bracketing

A binary bracketing is a BRACKETING built up entirely of binary operations. The number of binary bracketings of  $n$  letters (CATALAN'S PROBLEM) are given by the CATALAN NUMBERS  $C_{n-1}$ , where

$$C_n \equiv \frac{1}{n+1} \binom{2n}{n} = \frac{1}{n+1} \frac{(2n)!}{n!^2} = \frac{(2n)!}{(n+1)!n!},$$

where  $\binom{2n}{n}$  denotes a BINOMIAL COEFFICIENT and  $n!$  is the usual FACTORIAL, as first shown by Catalan in 1838. For example, for the four letters  $a$ ,  $b$ ,  $c$ , and  $d$  there are five possibilities:  $((ab)c)d$ ,  $(a(bc))d$ ,  $(ab)(cd)$ ,  $a((bc)d)$ , and  $a(b(cd))$ , written in shorthand as  $((xx)x)x$ ,  $(x(xx))x$ ,  $(xx)(xx)$ , and  $x(x(xx))$ .

### Binary Operator

An OPERATOR which takes two mathematical objects as input and returns a value is called a binary operator. Binary operators are called compositions by Rosenfeld (1968). Sets possessing a binary multiplication operation include the GROUP, GROUPOID, MONOID, QUASIGROUP, and SEMIGROUP. Sets possessing both a binary multiplication and a binary addition operation include the DIVISION ALGEBRA, FIELD, RING, RINGOID, SEMIRING, and UNIT RING.

### Binary Tree

A TREE with two BRANCHES at each FORK and with one or two LEAVES at the end of each BRANCH. (This definition corresponds to what is sometimes known as an "extended" binary tree.) The height of a binary tree is the number of levels within the TREE. For a binary tree of height  $H$  with  $n$  nodes,

$$H \leq n \leq 2^H - 1.$$

These extremes correspond to a balanced tree (each node except the LEAVES has a left and right CHILD, and all LEAVES are at the same level) and a degenerate tree (each node has only one outgoing BRANCH), respectively. For a search of data organized into a binary tree, the number of search steps  $S(n)$  needed to find an item is bounded by

$$\lg n \leq S(n) \leq n.$$

Partial balancing of an arbitrary tree into a so-called AVL binary search tree can improve search speed.

The number of binary trees with  $n$  internal nodes is the CATALAN NUMBER  $C_n$  (Sloane's A000108), and the number of binary trees of height  $b$  is given by Sloane's A001699.

#### Binet Forms

The two RECURRENCE SEQUENCES

$$U_n = mU_{n-1} + U_{n-2} \quad (1)$$

$$V_n = mV_{n-1} + V_{n-2} \quad (2)$$

with  $U_0 = 0$ ,  $U_1 = 1$  and  $V_0 = 2$ ,  $V_1 = m$ , can be solved for the individual  $U_n$  and  $V_n$ . They are given by

$$U_n = \frac{\alpha^n - \beta^n}{\Delta} \quad (3)$$

$$V_n = \alpha^n + \beta^n, \quad (4)$$

where

$$\Delta \equiv \sqrt{m^2 + 4} \quad (5)$$

$$\alpha \equiv \frac{m + \Delta}{2} \quad (6)$$

$$\beta \equiv \frac{m - \Delta}{2}. \quad (7)$$

A useful related identity is

$$U_{n-1} + U_{n+1} = V_n. \quad (8)$$

BINET'S FORMULA is a special case of the Binet form for  $U_n$  corresponding to  $m = 1$ .

see also FIBONACCI Q-MATRIX

#### Binet's Formula

A special case of the  $U_n$  BINET FORM with  $m = 0$ , corresponding to the  $n$ th FIBONACCI NUMBER,

$$F_n = \frac{(1 + \sqrt{5})^n - (1 - \sqrt{5})^n}{2^n \sqrt{5}}.$$

It was derived by Binet in 1843, although the result was known to Euler and Daniel Bernoulli more than a century earlier.

see also BINET FORMS, FIBONACCI NUMBER

#### Bing's Theorem

If  $M^3$  is a closed oriented connected 3-MANIFOLD such that every simple closed curve in  $M$  lies interior to a BALL in  $M$ , then  $M$  is HOMEOMORPHIC with the HYPERSPHERE,  $S^3$ .

see also BALL, HYPERSPHERE

#### Binomial

A POLYNOMIAL with 2 terms.

see also MONOMIAL, POLYNOMIAL, TRINOMIAL

#### Binomial Coefficient

The number of ways of picking  $n$  unordered outcomes from  $N$  possibilities. Also known as a COMBINATION. The binomial coefficients form the rows of PASCAL'S TRIANGLE. The symbols  ${}_N C_n$  and

$$\binom{N}{n} \equiv \frac{N!}{(N-n)!n!} \quad (1)$$

are used, where the latter is sometimes known as  $N$  CHOOSE  $n$ . The number of LATTICE PATHS from the ORIGIN  $(0, 0)$  to a point  $(a, b)$  is the BINOMIAL COEFFICIENT  $\binom{a+b}{a}$  (Hilton and Pedersen 1991).

For POSITIVE integer  $n$ , the BINOMIAL THEOREM gives

$$(x + a)^n = \sum_{k=0}^n \binom{n}{k} x^k a^{n-k}. \quad (2)$$

The FINITE DIFFERENCE analog of this identity is known as the CHU-VANDERMONDE IDENTITY. A similar formula holds for NEGATIVE INTEGRAL  $n$ ,

$$(x + a)^{-n} = \sum_{k=0}^{\infty} \binom{-n}{k} x^k a^{-n-k}. \quad (3)$$

A general identity is given by

$$\frac{(a+b)^n}{a} = \sum_{j=0}^n \binom{n}{j} (a-jc)^{j-1} (b+jc)^{n-j} \quad (4)$$

(Prudnikov *et al.* 1986), which gives the BINOMIAL THEOREM as a special case with  $c = 0$ .

The binomial coefficients satisfy the identities:

$$\binom{n}{0} = \binom{n}{n} = 1 \quad (5)$$

$$\binom{n}{k} = \binom{n}{n-k} = (-1)^k \binom{k-n-1}{k} \quad (6)$$

$$\binom{n+1}{k} = \binom{n}{k} + \binom{n}{k-1}. \quad (7)$$

Sums of powers include

$$\sum_{k=0}^n \binom{n}{k} = 2^n \quad (8)$$

$$\sum_{k=0}^n (-1)^k \binom{n}{k} = 0 \quad (9)$$

$$\sum_{k=0}^n \binom{n}{k} r^k = (1+r)^n \quad (10)$$

(the BINOMIAL THEOREM), and

$$\begin{aligned} \sum_{n=0}^{\infty} \binom{2n+s}{n} x^n &= {}_2F_1\left(\frac{1}{2}(s+1), \frac{1}{2}(s+2); s+1, 4x\right) \\ &= \frac{2^s}{(\sqrt{1-4x}+1)^s \sqrt{1-4x}}, \quad (11) \end{aligned}$$

where  ${}_2F_1(a, b; c; z)$  is a HYPERGEOMETRIC FUNCTION (Abramowitz and Stegun 1972, p. 555; Graham *et al.* 1994, p. 203). For NONNEGATIVE INTEGERS  $n$  and  $r$  with  $r \leq n+1$ ,

$$\begin{aligned} \sum_{k=0}^n \frac{(-1)^k}{k+1} \binom{n}{k} \left[ \sum_{j=0}^{r-1} (-1)^j \binom{n}{j} (r-j)^{n-k} \right. \\ \left. + \sum_{j=0}^{n-r} (-1)^j \binom{n}{j} (n+1-r-j)^{n-k} \right] = n!. \quad (12) \end{aligned}$$

Taking  $n = 2r - 1$  gives

$$\sum_{k=0}^n \frac{(-1)^k}{k+1} \binom{n}{k} \sum_{j=0}^{r-1} \binom{n}{j} (r-j)^{n-k} = \frac{1}{2} n!. \quad (13)$$

Another identity is

$$\sum_{k=0}^n \binom{n+k}{k} [x^{n+1}(1-x)^k + (1-x)^{n+1}x^k] = 1 \quad (14)$$

(Beeler *et al.* 1972, Item 42).

RECURRENCE RELATIONS of the sums

$$s_p \equiv \sum_{k=0}^n \binom{n}{k}^p \quad (15)$$

are given by

$$2s_1(n) - s_1(n+1) = 0 \quad (16)$$

$$-2(2n+1)s_2(n) + (n+1)s_2(n) = 0 \quad (17)$$

$$\begin{aligned} -8(n+1)^2 s_3(n) + (-16 - 21n - 7n^2) s_3(n+1) \\ + (n+2)^2 s_3(n+2) = 0 \quad (18) \end{aligned}$$

$$\begin{aligned} -4(n+1)(4n+3)(4n+5)s_4(n) \\ -2(2n+3)(3n^2+9n+7)s_4(n+1) \\ + (n+2)^3 s_4(n+2) = 0. \quad (19) \end{aligned}$$

This sequence for  $s_3$  cannot be expressed as a fixed number of hypergeometric terms (Petkovšek *et al.* 1996, p. 160).

A fascinating series of identities involving binomial coefficients times small powers are

$$\sum_{n=1}^{\infty} \frac{1}{\binom{2n}{n}} = \frac{1}{27} (2\pi\sqrt{3} + 9) = 0.7363998587 \dots \quad (20)$$

$$\sum_{n=1}^{\infty} \frac{1}{n \binom{2n}{n}} = \frac{1}{9} \pi \sqrt{3} = 0.6045997881 \dots \quad (21)$$

$$\sum_{n=1}^{\infty} \frac{1}{n^2 \binom{2n}{n}} = \frac{1}{3} \zeta(2) = \frac{1}{8} \pi^2 \quad (22)$$

$$\sum_{n=1}^{\infty} \frac{1}{n^4 \binom{2n}{n}} = \frac{17}{36} \zeta(4) = \frac{17}{3240} \pi^4 \quad (23)$$

(Comtet 1974, p. 89) and

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^3 \binom{2n}{n}} = \frac{2}{5} \zeta(3), \quad (24)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION (Le Lionnais 1983, pp. 29, 30, 41, 36, and 35; Guy 1994, p. 257).

As shown by Kummer in 1852, the exact POWER of  $p$  dividing  $\binom{a+b}{a}$  is equal to

$$\epsilon_0 + \epsilon_1 + \dots + \epsilon_t, \quad (25)$$

where this is the number of carries in performing the addition of  $a$  and  $b$  written in base  $b$  (Graham *et al.* 1989, Exercise 5.36; Ribenboim 1989; Vardi 1991, p. 68). Kummer's result can also be stated in the form that the

exponent of a PRIME  $p$  dividing  $\binom{n}{m}$  is given by the number of integers  $j \geq 0$  for which

$$\text{frac}(m/p^j) > \text{frac}(n/p^j), \quad (26)$$

where  $\text{frac}(x)$  denotes the FRACTIONAL PART of  $x$ . This inequality may be reduced to the study of the exponential sums  $\sum_n \Lambda(n)e(x/n)$ , where  $\Lambda(n)$  is the MANGOLDT FUNCTION. Estimates of these sums are given by Jutila (1974, 1975), but recent improvements have been made by Granville and Ramare (1996).

R. W. Gosper showed that

$$f(n) = \binom{n-1}{\frac{1}{2}(n-1)} \equiv (-1)^{(n-1)/2} \pmod{n} \quad (27)$$

for all PRIMES, and conjectured that it holds *only* for PRIMES. This was disproved when Skiena (1990) found it also holds for the COMPOSITE NUMBER  $n = 3 \times 11 \times 179$ . Vardi (1991, p. 63) subsequently showed that  $n = p^2$  is a solution whenever  $p$  is a WIEFERICH PRIME and that if  $n = p^k$  with  $k > 3$  is a solution, then so is  $n = p^{k-1}$ . This allowed him to show that the only solutions for COMPOSITE  $n < 1.3 \times 10^7$  are 5907, 1093<sup>2</sup>, and 3511<sup>2</sup>, where 1093 and 3511 are WIEFERICH PRIMES.

Consider the binomial coefficients  $\binom{2n-1}{n}$ , the first few of which are 1, 3, 10, 35, 126, ... (Sloane's A001700). The GENERATING FUNCTION is

$$\frac{1}{2} \left[ \frac{1}{\sqrt{1-4x}} - 1 \right] = x + 3x^2 + 10x^3 + 35x^4 + \dots \quad (28)$$

These numbers are SQUAREFREE only for  $n = 2, 3, 4, 6, 9, 10, 12, 36, \dots$  (Sloane's A046097), with no others less than  $n = 10,000$ . Erdős showed that the binomial coefficient  $\binom{n}{k}$  is never a POWER of an INTEGER for  $n \geq 3$  where  $k \neq 0, 1, n-1$ , and  $n$  (Le Lionnais 1983, p. 48).

The binomial coefficients  $\binom{n}{\lfloor n/2 \rfloor}$  are called CENTRAL BINOMIAL COEFFICIENTS, where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, although the subset of coefficients  $\binom{2n}{n}$  is sometimes also given this name. Erdős and Graham (1980, p. 71) conjectured that the CENTRAL BINOMIAL COEFFICIENT  $\binom{2n}{n}$  is *never* SQUAREFREE for  $n > 4$ , and this is sometimes known as the ERDŐS SQUAREFREE CONJECTURE. SÁRKÖZY'S THEOREM (Sárközy 1985) provides a partial solution which states that the BINOMIAL COEFFICIENT  $\binom{2n}{n}$  is never SQUAREFREE for all sufficiently large  $n \geq n_0$  (Vardi 1991). Granville and Ramare (1996) proved that the *only* SQUAREFREE values are  $n = 2$  and 4. Sander (1992) subsequently showed that  $\binom{2n \pm d}{n}$  are also never SQUAREFREE for sufficiently large  $n$  as long as  $d$  is not "too big."

For  $p, q$ , and  $r$  distinct PRIMES, then the above function satisfies

$$f(pqr)f(p)f(q)f(r) \equiv f(pq)f(pr)p(qr) \pmod{pqr} \quad (29)$$

(Vardi 1991, p. 66).

The binomial coefficient  $\binom{m}{n} \pmod{2}$  can be computed using the XOR operation  $n \text{ XOR } m$ , making PASCAL'S TRIANGLE mod 2 very easy to construct.

The binomial coefficient "function" can be defined as

$$C(x, y) \equiv \frac{x!}{y!(x-y)!} \quad (30)$$

(Fowler 1996), shown above. It has a very complicated GRAPH for NEGATIVE  $x$  and  $y$  which is difficult to render using standard plotting programs.

### Binomial Distribution

The probability of  $n$  successes in  $N$  BERNOULLI TRIALS is

$$P(n|N) = \binom{N}{n} p^n (1-p)^{N-n} = \frac{N!}{n!(N-n)!} p^n q^{N-n}. \quad (1)$$

The probability of obtaining more successes than the  $n$  observed is

$$P = \sum_{k=n+1}^N \binom{N}{k} p^k (1-p)^{N-k} = I_p(n+1, N-N), \quad (2)$$

where

$$I_x(a, b) \equiv \frac{B(x; a, b)}{B(a, b)}, \quad (3)$$

$B(a, b)$  is the BETA FUNCTION, and  $B(x; a, b)$  is the incomplete BETA FUNCTION. The CHARACTERISTIC FUNCTION is

$$\phi(t) = (q + pe^{it})^n. \quad (4)$$

The MOMENT-GENERATING FUNCTION  $M$  for the distribution is

$$\begin{aligned} M(t) &= \langle e^{tn} \rangle = \sum_{n=0}^N e^{tn} \binom{N}{n} p^n q^{N-n} \\ &= \sum_{n=0}^N \binom{N}{n} (pe^t)^n (1-p)^{N-n} \\ &= [pe^t + (1-p)]^N \end{aligned} \quad (5)$$

$$M'(t) = N[pe^t + (1-p)]^{N-1} (pe^t) \quad (6)$$

$$\begin{aligned} M''(t) &= N(N-1)[pe^t + (1-p)]^{N-2} (pe^t)^2 \\ &\quad + N[pe^t + (1-p)]^{N-1} (pe^t). \end{aligned} \quad (7)$$

The MEAN is

$$\mu = M'(0) = N(p + 1 - p)p = Np. \quad (8)$$

The MOMENTS about 0 are

$$\mu'_1 = \mu = Np \quad (9)$$

$$\mu'_2 = Np(1-p + Np) \quad (10)$$

$$\mu'_3 = Np(1-3p + 3Np + 2p^2 - 3NP^2 + N^2p^2) \quad (11)$$

$$\begin{aligned} \mu'_4 &= Np(1-7p + 7Np + 12p^2 - 18Np^2 + 6N^2p^2 \\ &\quad - 6p^3 + 11Np^3 - 6N^2p^3 + N^3p^3), \end{aligned} \quad (12)$$

so the MOMENTS about the MEAN are

$$\begin{aligned} \mu_2 &= \sigma^2 = [N(N-1)p^2 + Np] - (Np)^2 \\ &= N^2p^2 - Np^2 + Np - N^2p^2 \\ &= Np(1-p) = Npq \end{aligned} \quad (13)$$

$$\begin{aligned} \mu_3 &= \mu'_3 - 3\mu'_2\mu'_1 + 2(\mu'_1)^3 \\ &= Np(1-p)(1-2p) \end{aligned} \quad (14)$$

$$\begin{aligned} \mu_4 &= \mu'_4 - 4\mu'_3\mu'_1 + 6\mu'_2(\mu'_1)^2 - 3(\mu'_1)^4 \\ &= Np(1-p)[3p^2(2-N) + 3p(N-2) + 1]. \end{aligned} \quad (15)$$

The SKEWNESS and KURTOSIS are

$$\begin{aligned}\gamma_1 &= \frac{\mu_3}{\sigma^3} = \frac{Np(1-p)(1-2p)}{[Np(1-p)]^{3/2}} \\ &= \frac{1-2p}{\sqrt{Np(1-p)}} = \frac{q-p}{\sqrt{Npq}}\end{aligned}\quad (16)$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = \frac{6p^2 - 6p + 1}{Np(1-p)} = \frac{1-6pq}{Npq}.\quad (17)$$

An approximation to the Bernoulli distribution for large  $N$  can be obtained by expanding about the value  $\tilde{n}$  where  $P(n)$  is a maximum, i.e., where  $dP/dn = 0$ . Since the LOGARITHM function is MONOTONIC, we can instead choose to expand the LOGARITHM. Let  $n \equiv \tilde{n} + \eta$ , then

$$\ln[P(n)] = \ln[P(\tilde{n})] + B_1\eta + \frac{1}{2}B_2\eta^2 + \frac{1}{3!}B_3\eta^3 + \dots, \quad (18)$$

where

$$B_k \equiv \left[ \frac{d^k \ln[P(n)]}{dn^k} \right]_{n=\tilde{n}}. \quad (19)$$

But we are expanding about the maximum, so, by definition,

$$B_1 = \left[ \frac{d \ln[P(n)]}{dn} \right]_{n=\tilde{n}} = 0. \quad (20)$$

This also means that  $B_2$  is negative, so we can write  $B_2 = -|B_2|$ . Now, taking the LOGARITHM of (1) gives

$$\ln[P(n)] = \ln N! - \ln n! - \ln(N-n)! + n \ln p + (N-n) \ln q. \quad (21)$$

For large  $n$  and  $N-n$  we can use STIRLING'S APPROXIMATION

$$\ln(n!) \approx n \ln n - n, \quad (22)$$

so

$$\frac{d[\ln(n!)]}{dn} \approx (\ln n + 1) - 1 = \ln n \quad (23)$$

$$\begin{aligned}\frac{d[\ln(N-n)!]}{dn} &\approx \frac{d}{dn} [(N-n) \ln(N-n) - (N-n)] \\ &= \left[ -\ln(N-n) + (N-n) \frac{-1}{N-n} + 1 \right] \\ &= -\ln(N-n),\end{aligned}\quad (24)$$

and

$$\frac{d \ln[P(n)]}{dn} \approx -\ln n + \ln(N-n) + \ln p - \ln q. \quad (25)$$

To find  $\tilde{n}$ , set this expression to 0 and solve for  $n$ ,

$$\ln \left( \frac{N-\tilde{n}}{\tilde{n}} \frac{p}{q} \right) = 0 \quad (26)$$

$$\frac{N-\tilde{n}}{\tilde{n}} \frac{p}{q} = 1 \quad (27)$$

$$(N-\tilde{n})p = \tilde{n}q \quad (28)$$

$$\tilde{n}(q+p) = \tilde{n} = Np, \quad (29)$$

since  $p+q=1$ . We can now find the terms in the expansion

$$\begin{aligned}B_2 &\equiv \left[ \frac{d^2 \ln[P(n)]}{dn^2} \right]_{n=\tilde{n}} = -\frac{1}{\tilde{n}} - \frac{1}{N-\tilde{n}} \\ &= -\frac{1}{Np} - \frac{1}{N(1-p)} = -\frac{1}{N} \left( \frac{1}{p} + \frac{1}{q} \right) \\ &= -\frac{1}{N} \left( \frac{p+q}{pq} \right) = -\frac{1}{Npq} = -\frac{1}{N(1-p)}\end{aligned}\quad (30)$$

$$\begin{aligned}B_3 &\equiv \left[ \frac{d^3 \ln[P(n)]}{dn^3} \right]_{n=\tilde{n}} = \frac{1}{\tilde{n}^2} - \frac{1}{(N-\tilde{n})^2} \\ &= \frac{1}{N^2 p^2} - \frac{1}{N^2 q^2} = \frac{q^2 - p^2}{N^2 p^2 q^2} \\ &= \frac{(1-2p+p^2) - p^2}{N^2 p^2 (1-p)^2} = \frac{1-2p}{N^2 p^2 (1-p)^2}\end{aligned}\quad (31)$$

$$\begin{aligned}B_4 &\equiv \left[ \frac{d^4 \ln[P(n)]}{dn^4} \right]_{n=\tilde{n}} = -\frac{2}{\tilde{n}^3} - \frac{2}{(N-\tilde{n})^3} \\ &= -2 \left( \frac{1}{N^3 p^3} + \frac{1}{N^3 q^3} \right) = -\frac{2(p^3 + q^3)}{N^3 p^3 q^3} \\ &= \frac{2(p^2 - pq + q^2)}{N^3 p^3 q^3} \\ &= \frac{2[p^2 - p(1-p) + (1-2p+p^2)]}{N^3 p^3 (1-p^3)} \\ &= \frac{2(3p^2 - 3p + 1)}{N^3 p^3 (1-p^3)}.\end{aligned}\quad (32)$$

Now, treating the distribution as continuous,

$$\lim_{N \rightarrow \infty} \sum_{n=0}^N P(n) \approx \int_{-\infty}^{\infty} P(n) dn = \int_{-\infty}^{\infty} P(\tilde{n} + \eta) d\eta = 1. \quad (33)$$

Since each term is of order  $1/N \sim 1/\sigma^2$  smaller than the previous, we can ignore terms higher than  $B_2$ , so

$$P(n) = P(\tilde{n}) e^{-|B_2|\eta^2/2}. \quad (34)$$

The probability must be normalized, so

$$\int_{-\infty}^{\infty} P(\tilde{n}) e^{-|B_2|\eta^2/2} d\eta = P(\tilde{n}) \sqrt{\frac{2\pi}{|B_2|}} = 1, \quad (35)$$

and

$$\begin{aligned}P(n) &= \sqrt{\frac{|B_2|}{2\pi}} e^{-|B_2|(n-\tilde{n})^2/2} \\ &= \frac{1}{\sqrt{2\pi Npq}} \exp \left[ -\frac{(n-Np)^2}{2Npq} \right].\end{aligned}\quad (36)$$

Defining  $\sigma^2 = 2Npq$ ,

$$P(n) = \frac{1}{\sigma\sqrt{2\pi}} \exp \left[ -\frac{(n-\tilde{n})^2}{2\sigma^2} \right], \quad (37)$$

which is a GAUSSIAN DISTRIBUTION. For  $p \ll 1$ , a different approximation procedure shows that the binomial distribution approaches the POISSON DISTRIBUTION. The first CUMULANT is

$$\kappa_1 = np, \quad (38)$$

and subsequent CUMULANTS are given by the RECURRENCE RELATION

$$\kappa_{r+1} = pq \frac{d\kappa_r}{dp}. \quad (39)$$

Let  $x$  and  $y$  be independent binomial RANDOM VARIABLES characterized by parameters  $n, p$  and  $m, p$ . The CONDITIONAL PROBABILITY of  $x$  given that  $x + y = k$  is

$$\begin{aligned} P(x = i | x + y = k) &= \frac{P(x = i, x + y = k)}{P(x + y = k)} \\ &= \frac{P(x = i, y = k - i)}{P(x + y = k)} = \frac{P(x = i)P(y = k - i)}{P(x + y = k)} \\ &= \frac{\binom{n}{i} p^i (1 - p)^{n-i} \binom{m}{k-i} p^{k-i} (1 - p)^{m-(k-i)}}{\binom{n+m}{k} p^k (1 - p)^{n+m-k}} \\ &= \frac{\binom{n}{i} \binom{m}{k-i}}{\binom{n+m}{k}}. \end{aligned} \quad (40)$$

Note that this is a HYPERGEOMETRIC DISTRIBUTION!

### Binomial Expansion

see BINOMIAL SERIES

### Binomial Formula

see BINOMIAL SERIES, BINOMIAL THEOREM

### Binomial Number

A number of the form  $a^n \pm b^n$ , where  $a, b$ , and  $n$  are INTEGERS. They can be factored algebraically

$$a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + \dots + ab^{n-2} + b^{n-1}) \quad (1)$$

$$a^n + b^n = (a + b)(a^{n-1} - a^{n-2}b + \dots - ab^{n-2} + b^{n-1}) \quad (2)$$

$$a^{nm} - b^{nm} = (a^m - b^m)[a^{m(n-1)} + a^{m(n-2)}b^m + \dots + b^{m(n-1)}]. \quad (3)$$

In 1770, Euler proved that if  $(a, b) = 1$ , then every FACTOR of

$$a^{2^n} + b^{2^n} \quad (4)$$

is either 2 or of the form  $2^{n+1}K + 1$ . If  $p$  and  $q$  are PRIMES, then

$$\frac{a^{pq} - 1}{(a^p - 1)(a^q - 1)} - 1 \quad (5)$$

is DIVISIBLE by every PRIME FACTOR of  $a^{p-1}$  not dividing  $a^q - 1$ .

### Binomial Series

For  $|x| < 1$ ,

$$(1 + x)^n = \sum_{k=0}^n \binom{n}{k} x^k \quad (1)$$

$$= \binom{n}{0} x^0 + \binom{n}{1} x^1 + \binom{n}{2} x^2 + \dots \quad (2)$$

$$= 1 + \frac{n!}{1!(n-1)!} x + \frac{n!}{(n-2)!2!} x^2 + \dots \quad (3)$$

$$= 1 + nx + \frac{n(n-1)}{2} x^2 + \dots \quad (4)$$

The binomial series also has the CONTINUED FRACTION representation

$$(1 + x)^n = \frac{1}{1 - \frac{nx}{1 + \frac{1 \cdot (1+n)x}{1 \cdot 2} + \frac{1 \cdot (1-n)x}{2 \cdot 3} + \frac{2(2+n)x}{3 \cdot 4} + \frac{2(2-n)x}{4 \cdot 5} + \frac{3(3+n)x}{5 \cdot 6} + \dots}}. \quad (5)$$

### Binomial Theorem

The theorem that, for INTEGRAL POSITIVE  $n$ ,

$$(x + a)^n = \sum_{k=0}^n \frac{n!}{k!(n-k)!} x^k a^{n-k} = \sum_{k=0}^n \binom{n}{k} x^k a^{n-k},$$

the so-called BINOMIAL SERIES, where  $\binom{n}{k}$  are BINOMIAL COEFFICIENTS. The theorem was known for the case  $n = 2$  by Euclid around 300 BC, and stated in its modern form by Pascal in 1665. Newton (1676) showed that a similar formula (with INFINITE upper limit) holds for NEGATIVE INTEGRAL  $n$ ,

$$(x + a)^{-n} = \sum_{k=0}^{\infty} \binom{-n}{k} x^k a^{-n-k},$$

the so-called NEGATIVE BINOMIAL SERIES, which converges for  $|x| > |a|$ .

### Binomial Triangle

see PASCAL'S TRIANGLE

### Binormal Developable

A RULED SURFACE  $M$  is said to be a binormal developable of a curve  $\mathbf{y}$  if  $M$  can be parameterized by  $\mathbf{x}(u, v) = \mathbf{y}(u) + v\hat{\mathbf{B}}(u)$ , where  $\hat{\mathbf{B}}$  is the BINORMAL VECTOR.

see also NORMAL DEVELOPABLE, TANGENT DEVELOPABLE

#### References

- Gray, A. "Developables." §17.6 in *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 352–354, 1993.

### Binormal Vector

$$\hat{\mathbf{B}} \equiv \hat{\mathbf{T}} \times \hat{\mathbf{N}} \quad (1)$$

$$= \frac{\mathbf{r}' \times \mathbf{r}''}{|\mathbf{r}' \times \mathbf{r}''|}, \quad (2)$$

where the unit TANGENT VECTOR  $\hat{\mathbf{T}}$  and unit "principal" NORMAL VECTOR  $\hat{\mathbf{N}}$  are defined by

$$\hat{\mathbf{T}} \equiv \frac{\mathbf{r}'(s)}{|\mathbf{r}'(s)|} \quad (3)$$

$$\hat{\mathbf{N}} \equiv \frac{\mathbf{r}''(s)}{|\mathbf{r}''(s)|} \quad (4)$$

Here,  $\mathbf{r}$  is the RADIUS VECTOR,  $s$  is the ARC LENGTH,  $\tau$  is the TORSION, and  $\kappa$  is the CURVATURE. The binormal vector satisfies the remarkable identity

$$[\dot{\mathbf{B}}, \ddot{\mathbf{B}}, \ddot{\ddot{\mathbf{B}}}] = \tau^5 \frac{d}{ds} \left( \frac{\kappa}{\tau} \right). \quad (5)$$

**Biplanar Double Point**

see ISOLATED SINGULARITY

**Bipolar Coordinates**

Bipolar coordinates are a 2-D system of coordinates. There are two commonly defined types of bipolar coordinates, the first of which is defined by

$$x = \frac{a \sinh v}{\cosh v - \cos u} \quad (1)$$

$$y = \frac{a \sin u}{\cosh v - \cos u}, \quad (2)$$

where  $u \in [0, 2\pi)$ ,  $v \in (-\infty, \infty)$ . The following identities show that curves of constant  $u$  and  $v$  are CIRCLES in  $xy$ -space.

$$x^2 + (y - a \cot u)^2 = a^2 \csc^2 u \quad (3)$$

$$(x - a \coth v)^2 + y^2 = a^2 \operatorname{csch}^2 v. \quad (4)$$

The SCALE FACTORS are

$$h_u = \frac{a}{\cosh v - \cos u} \quad (5)$$

$$h_v = \frac{a}{\cosh v - \cos u}. \quad (6)$$

The LAPLACIAN is

$$\nabla^2 = \frac{(\cosh v - \cos u)^2}{a^2} \left( \frac{\partial^2}{\partial u^2} + \frac{\partial^2}{\partial v^2} \right). \quad (7)$$

LAPLACE'S EQUATION is separable.

Two-center bipolar coordinates are two coordinates giving the distances from two fixed centers  $r_1$  and  $r_2$ , sometimes denoted  $r$  and  $r'$ . For two-center bipolar coordinates with centers at  $(\pm c, 0)$ ,

$$r_1^2 = (x + c)^2 + y^2 \quad (8)$$

$$r_2^2 = (x - c)^2 + y^2. \quad (9)$$

Combining (8) and (9) gives

$$r_1^2 - r_2^2 = 4cx. \quad (10)$$

Solving for CARTESIAN COORDINATES  $x$  and  $y$  gives

$$x = \frac{r_1^2 - r_2^2}{4c} \quad (11)$$

$$y = \pm \frac{1}{4c} \sqrt{16c^2 r_1^2 - (r_1^2 - r_2^2 + 4c^2)}. \quad (12)$$

Solving for POLAR COORDINATES gives

$$r = \sqrt{\frac{r_1^2 + r_2^2 - 2c^2}{2}} \quad (13)$$

$$\theta = \tan^{-1} \left[ \sqrt{\frac{8c^2(r_1^2 + r_2^2 - 2c^2)}{r_1^2 - r_2^2}} - 1 \right]. \quad (14)$$

**References**

- Lockwood, E. H. "Bipolar Coordinates." Ch. 25 in *A Book of Curves*. Cambridge, England: Cambridge University Press, pp. 186–190, 1967.

**Bipolar Cylindrical Coordinates**

A set of CURVILINEAR COORDINATES defined by

$$x = \frac{a \sinh v}{\cosh v - \cos u} \quad (1)$$

$$y = \frac{a \sin u}{\cosh v - \cos u} \quad (2)$$

$$z = z, \quad (3)$$

where  $u \in [0, 2\pi)$ ,  $v \in (-\infty, \infty)$ , and  $z \in (-\infty, \infty)$ . There are several notational conventions, and whereas  $(u, v, z)$  is used in this work, Arfken (1970) prefers

$(\eta, \xi, z)$ . The following identities show that curves of constant  $u$  and  $v$  are CIRCLES in  $xy$ -space.

$$x^2 + (y - a \cot u)^2 = a^2 \csc^2 u \tag{4}$$

$$(x - a \coth v)^2 + y^2 = a^2 \operatorname{csch}^2 v. \tag{5}$$

The SCALE FACTORS are

$$h_u = \frac{a}{\cosh v - \cos u} \tag{6}$$

$$h_v = \frac{a}{\cosh v - \cos u} \tag{7}$$

$$h_z = 1. \tag{8}$$

The LAPLACIAN is

$$\nabla^2 = \frac{(\cosh v - \cos u)^2}{a^2} \left( \frac{\partial^2}{\partial u^2} + \frac{\partial^2}{\partial v^2} \right) + \frac{\partial^2}{\partial z^2}. \tag{9}$$

LAPLACE'S EQUATION is not separable in BIPOLAR CYLINDRICAL COORDINATES, but it is in 2-D BIPOLAR COORDINATES.

Bipyramid

see DIPYRAMID

Biquadratfree

A number is said to be biquadratfree if its PRIME decomposition contains no tripled factors. All PRIMES are therefore trivially biquadratfree. The biquadratfree numbers are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 17, ... (Sloane's A046100). The biquadratful numbers (i.e., those that contain at least one biquadrate) are 16, 32, 48, 64, 80, 81, 96, ... (Sloane's A046101). The number of biquadratfree numbers less than 10, 100, 1000, ... are 10, 93, 925, 9240, 92395, 923939, ..., and their asymptotic density is  $1/\zeta(4) = 90/\pi^4 \approx 0.923938$ , where  $\zeta(n)$  is the RIEMANN ZETA FUNCTION.

Biquadratic Equation

see QUARTIC EQUATION

Biquadratic Number

A biquadratic number is a fourth POWER,  $n^4$ . The first few biquadratic numbers are 1, 16, 81, 256, 625, ... (Sloane's A000583). The minimum number of squares needed to represent the numbers 1, 2, 3, ... are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 1, 2, 3, 4, 5, ... (Sloane's A002377), and the number of distinct ways to represent the numbers 1, 2, 3, ... in terms of biquadratic numbers are 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, ... A brute-force algorithm for enumerating the biquadratic permutations of  $n$  is repeated application of the GREEDY ALGORITHM.

Every POSITIVE integer is expressible as a SUM of (at most)  $g(4) = 19$  biquadratic numbers (WARING'S PROBLEM). Davenport (1939) showed that  $G(4) = 16$ , meaning that all sufficiently large integers require only 16 biquadratic numbers. The following table gives the first few numbers which require 1, 2, 3, ..., 19 biquadratic numbers to represent them as a sum, with the sequences for 17, 18, and 19 being finite.

#	Sloane	Numbers
1	000290	1, 16, 81, 256, 625, 1296, 2401, 4096, ...
2	003336	2, 17, 32, 82, 97, 162, 257, 272, ...
3	003337	3, 18, 33, 48, 83, 98, 113, 163, ...
4	003338	4, 19, 34, 49, 64, 84, 99, 114, 129, ...

**Birch Conjecture**

see SWINNERTON-DYER CONJECTURE

**Birch-Swinnerton-Dyer Conjecture**

see SWINNERTON-DYER CONJECTURE

**Birkhoff's Ergodic Theorem**

Let  $T$  be an ergodic ENDOMORPHISM of the PROBABILITY SPACE  $X$  and let  $f : X \rightarrow \mathbb{R}$  be a real-valued MEASURABLE FUNCTION. Then for ALMOST EVERY  $x \in X$ , we have

$$\frac{1}{n} \sum_{j=1}^n f \circ T^j(x) \rightarrow \int f \, dm$$

as  $n \rightarrow \infty$ . To illustrate this, take  $f$  to be the characteristic function of some SUBSET  $A$  of  $X$  so that

$$f(x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{if } x \notin A. \end{cases}$$

The left-hand side of (-1) just says how often the orbit of  $x$  (that is, the points  $x, Tx, T^2x, \dots$ ) lies in  $A$ , and the right-hand side is just the MEASURE of  $A$ . Thus, for an ergodic ENDOMORPHISM, "space-averages = time-averages almost everywhere." Moreover, if  $T$  is continuous and uniquely ergodic with BOREL PROBABILITY MEASURE  $m$  and  $f$  is continuous, then we can replace the ALMOST EVERYWHERE convergence in (-1) to everywhere.

**Birotunda**

Two adjoined ROTUNDAS.

**Birthday Attack**

Birthday attacks are a class of brute-force techniques used in an attempt to solve a class of cryptographic hash function problems. These methods take advantage of functions which, when supplied with a random input, return one of  $k$  equally likely values. By repeatedly evaluating the function for different inputs, the same output is expected to be obtained after about  $1.2\sqrt{k}$  evaluations.

### Birthday Problem

Consider the probability  $Q_1(n, d)$  that *no two people* out of a group of  $n$  will have matching birthdays out of  $d$  equally possible birthdays. Start with an arbitrary person's birthday, then note that the probability that the second person's birthday is different is  $(d-1)/d$ , that the third person's birthday is different from the first two is  $[(d-1)/d][(d-2)/d]$ , and so on, up through the  $n$ th person. Explicitly,

$$Q_1(n, d) = \frac{d-1}{d} \frac{d-2}{d} \dots \frac{d-(n-1)}{d} = \frac{(d-1)(d-2) \dots [d-(n-1)]}{d^n}. \quad (1)$$

But this can be written in terms of FACTORIALS as

$$Q_1(n, d) = \frac{d!}{(d-n)!d^n}, \quad (2)$$

so the probability  $P_2(n, 365)$  that two people out of a group of  $n$  *do have the same birthday* is therefore

$$P_2(n, d) = 1 - Q_1(n, d) = 1 - \frac{d!}{(d-n)!d^n}. \quad (3)$$

If 365-day years have been assumed, i.e., the existence of leap days is ignored, then the number of people needed for there to be at least a 50% chance that two share birthdays is the smallest  $n$  such that  $P_2(n, 365) \geq 1/2$ . This is given by  $n = 23$ , since

$$P_2(23, 365) = \frac{38093904702297390785243708291056390518886454060947061}{75091883268515350125426207425223147563269805908203125} \approx 0.507297. \quad (4)$$

The number of people needed to obtain  $P_2(n, 365) \geq 1/2$  for  $n = 1, 2, \dots$ , are 2, 2, 3, 3, 3, 4, 4, 4, 4, 5, ... (Sloane's A033810).

The probability  $P_2(n, d)$  can be estimated as

$$P_2(n, d) \approx 1 - e^{-n(n-1)/2d} \quad (5)$$

$$\approx 1 - \left(1 - \frac{n}{2d}\right)^{n-1}, \quad (6)$$

where the latter has error

$$\epsilon < \frac{n^3}{6(d-n+1)^2} \quad (7)$$

(Sayrafiezadeh 1994).

In general, let  $Q_i(n, d)$  denote the probability that a birthday is shared by exactly  $i$  (and no more) people out of a group of  $n$  people. Then the probability that a birthday is shared by  $k$  or more people is given by

$$P_k(n, d) = 1 - \sum_{i=1}^{k-1} Q_i(n, d). \quad (8)$$

$Q_2$  can be computed explicitly as

$$\begin{aligned} Q_2(n, d) &= \frac{n!}{d^n} \sum_{i=1}^{\lfloor n/2 \rfloor} \frac{1}{2^i} \binom{d}{i} \binom{d-i}{n-2i} \\ &= \frac{n!}{d^n} \sum_{i=1}^{\lfloor n/2 \rfloor} \frac{d!}{2^i i! (n-2i)! (d-n+i)!} \\ &= \frac{(-1)^n}{d^n} \left[ 2^{-n/2} \Gamma(1+n) P_n^{(-d)}\left(\frac{1}{2}\sqrt{2}\right) - \frac{\Gamma(1+d)}{\Gamma(1+d-n)} \right], \end{aligned} \quad (9)$$

where  $\binom{n}{m}$  is a BINOMIAL COEFFICIENT,  $\Gamma(n)$  is a GAMMA FUNCTION, and  $P_n^{(\lambda)}(x)$  is an ULTRASPHERICAL POLYNOMIAL. This gives the explicit formula for  $P_3(n, d)$  as

$$\begin{aligned} P_3(n, d) &= 1 - Q_1(n, d) - Q_2(n, d) \\ &= 1 + \frac{(-1)^{n+1} \Gamma(n+1) P_n^{(-d)}(2^{-1/2})}{2^{n/2} d^n}. \end{aligned} \quad (10)$$

$Q_3(n, d)$  cannot be computed in entirely closed form, but a partially reduced form is

$$\begin{aligned} Q_3(n, d) &= \frac{\Gamma(d+1)}{d^n} \left[ \frac{(-1)^n F\left(\frac{9}{8}\right) - F\left(-\frac{9}{8}\right)}{\Gamma(d-n+1)} \right. \\ &\quad \left. + (-1)^n \Gamma(1+n) \sum_{i=1}^{\lfloor n/3 \rfloor} \frac{(-3)^{-i} 2^{(i-n)/2} P_{n-3i}^{(-d)}\left(\frac{1}{2}\sqrt{2}\right)}{\Gamma(d-i+1) \Gamma(i+1)} \right], \end{aligned} \quad (11)$$

where

$$F = F(n, d, a) \equiv 1 - {}_3F_2 \left[ \begin{matrix} \frac{1}{3}(1-n), \frac{1}{3}(2-n), -\frac{1}{3} \\ \frac{1}{2}(d-n+1), \frac{1}{2}(d-n+2) \end{matrix}; a \right] \quad (12)$$

and  ${}_3F_2(a, b, c; d, e; z)$  is a GENERALIZED HYPERGEOMETRIC FUNCTION.

In general,  $Q_k(n, d)$  can be computed using the RECURRENCE RELATION

$$\begin{aligned} Q_k(n, d) &= \sum_{i=1}^{\lfloor n/k \rfloor} \left[ \frac{n! d!}{d^{ik} i! (k!)^i (n-ik)! (d-i)!} \right. \\ &\quad \left. \times \sum_{j=1}^{k-1} Q_j(n-k, d-i) \frac{(d-i)^{n-ik}}{d^{n-ik}} \right] \end{aligned} \quad (13)$$

(Finch). However, the time to compute this recursive function grows exponentially with  $k$  and so rapidly becomes unwieldy. The minimal number of people to give a 50% probability of having at least  $n$  coincident birthdays is 1, 23, 88, 187, 313, 460, 623, 798, 985, 1181, 1385, 1596, 1813, ... (Sloane's A014088; Diaconis and Mosteller 1989).

A good approximation to the number of people  $n$  such that  $p = P_k(n, d)$  is some given value can be given by solving the equation

$$ne^{-n/(dk)} = \left[ d^{k-1} k! \ln \left( \frac{1}{1-p} \right) \left( 1 - \frac{n}{d(k+1)} \right) \right]^{1/k} \quad (14)$$

for  $n$  and taking  $\lceil n \rceil$ , where  $\lceil n \rceil$  is the CEILING FUNCTION (Diaconis and Mosteller 1989). For  $p = 0.5$  and  $k = 1, 2, 3, \dots$ , this formula gives  $n = 1, 23, 88, 187, 313, 459, 722, 797, 983, 1179, 1382, 1592, 1809, \dots$ , which differ from the true values by from 0 to 4. A much simpler but also poorer approximation for  $n$  such that  $p = 0.5$  for  $k < 20$  is given by

$$n = 47(k - 1.5)^{3/2} \quad (15)$$

(Diaconis and Mosteller 1989), which gives 86, 185, 307, 448, 606, 778, 965, 1164, 1376, 1599, 1832, ... for  $k = 3, 4, \dots$ .

The "almost" birthday problem, which asks the number of people needed such that two have a birthday within a day of each other, was considered by Abramson and Moser (1970), who showed that 14 people suffice. An approximation for the minimum number of people needed to get a 50-50 chance that two have a match within  $k$  days out of  $d$  possible is given by

$$n(k, d) = 1.2 \sqrt{\frac{d}{2k+1}} \quad (16)$$

(Sevast'yanov 1972, Diaconis and Mosteller 1989).

### Bisected Perimeter Point

see NAGEL POINT

### Bisection Procedure

Given an interval  $[a, b]$ , let  $a_n$  and  $b_n$  be the endpoints at the  $n$ th iteration and  $r_n$  be the  $n$ th approximate solution. Then, the number of iterations required to obtain an error smaller than  $\epsilon$  is found as follows.

$$b_n - a_n = \frac{1}{2^{n-1}}(b - a) \quad (1)$$

$$r_n \equiv \frac{1}{2}(a_n + b_n) \quad (2)$$

$$|r_n - r| \leq \frac{1}{2}(b_n - a_n) = 2^{-n}(b - a) < \epsilon \quad (3)$$

$$-n \ln 2 < \ln \epsilon - \ln(b - a), \quad (4)$$

so

$$n > \frac{\ln(b - a) - \ln \epsilon}{\ln 2}. \quad (5)$$

### Bisector

Bisection is the division of a given curve or figure into two equal parts (halves).

see also ANGLE BISECTOR, BISECTION PROCEDURE, EXTERIOR ANGLE BISECTOR, HALF, HEMISPHERE, LINE BISECTOR, PERPENDICULAR BISECTOR, TRISECTION

### Bishop's Inequality

Let  $V(r)$  be the volume of a BALL of radius  $r$  in a complete  $n$ -D RIEMANNIAN MANIFOLD with RICCI CURVATURE  $\geq (n-1)\kappa$ . Then  $V(r) \geq V_\kappa(r)$ , where  $V_\kappa$  is the volume of a BALL in a space having constant SECTIONAL CURVATURE. In addition, if equality holds for some BALL, then this BALL is ISOMETRIC to the BALL of radius  $r$  in the space of constant SECTIONAL CURVATURE  $\kappa$ .

### Bishops Problem

Find the maximum number of bishops  $B(n)$  which can be placed on an  $n \times n$  CHESSBOARD such that no two attack each other. The answer is  $2n-2$  (Dudeney 1970, Madachy 1979), giving the sequence 2, 4, 6, 8, ... (the EVEN NUMBERS) for  $n = 2, 3, \dots$ . One maximal solution for  $n = 8$  is illustrated above. The number of distinct maximal arrangements of bishops for  $n = 1, 2, \dots$  are 1, 4, 26, 260, 3368, ... (Sloane's A002465). The number of rotationally and reflectively distinct solutions on an  $n \times n$  board for  $n \geq 2$  is

$$B(n) = \begin{cases} 2^{(n-4)/2} [2^{(n-2)/2} + 1] & \text{for } n \text{ even} \\ 2^{(n-3)/2} [2^{(n-3)/2} + 1] & \text{for } n \text{ odd} \end{cases}$$

(Dudeney 1970, p. 96; Madachy 1979, p. 45; Pickover 1995). An equivalent formula is

$$B(n) = 2^{n-3} + 2^{\lfloor (n-1)/2 \rfloor - 1},$$

where  $\lfloor n \rfloor$  is the FLOOR FUNCTION, giving the sequence for  $n = 1, 2, \dots$  as 1, 1, 2, 3, 6, 10, 20, 36, ... (Sloane's A005418).

The minimum number of bishops needed to occupy or attack all squares on an  $n \times n$  CHESSBOARD is  $n$ , arranged as illustrated above.

### Bislit Cube

The 8-VERTEX graph consisting of a CUBE in which two opposite faces have DIAGONALS oriented PERPENDICULAR to each other.

see also BIDIAKIS CUBE, CUBE, CUBICAL GRAPH

**Bispherical Coordinates**

A system of CURVILINEAR COORDINATES defined by

$$x = \frac{a \sin \xi \cos \phi}{\cosh \eta - \cos \xi} \quad (1)$$

$$y = \frac{a \sin \xi \sin \phi}{\cosh \eta - \cos \xi} \quad (2)$$

$$z = \frac{a \sinh \eta}{\cosh \eta - \cos \xi} \quad (3)$$

The SCALE FACTORS are

$$h_\xi = \frac{a}{\cos \eta - \cos \xi} \quad (4)$$

$$h_\eta = \frac{a}{\cosh \eta - \cos \xi} \quad (5)$$

$$h_\phi = \frac{a \sin \xi}{\cosh \eta - \cos \xi} \quad (6)$$

The LAPLACIAN is

$$\begin{aligned} \nabla^2 = & \left( \frac{-\cos u \cot^2 u + 3 \cosh v \cot^2 u}{\cosh v - \cos u} \right. \\ & \left. + \frac{-3 \cosh^2 v \cot u \csc u + \cosh^3 v \csc^2 u}{\cosh v - \cos u} \right) \frac{\partial}{\partial \phi^2} \\ & + (\cos u - \cosh v) \sinh v \frac{\partial}{\partial v} + (\cosh^2 v - \cos u)^2 \frac{\partial^2}{\partial v^2} \\ & + (\cosh v - \cos u)(\cosh v \cot u - \sin u - \cos u \cot u) \frac{\partial}{\partial u} \\ & + (\cosh^2 v - \cos u)^2 \frac{\partial^2}{\partial u^2}. \end{aligned} \quad (7)$$

In bispherical coordinates, LAPLACE'S EQUATION is separable, but the HELMHOLTZ DIFFERENTIAL EQUATION is not.

**Black-Scholes Theory**

The theory underlying financial derivatives which involves "stochastic calculus" and assumes an uncorrelated LOG NORMAL DISTRIBUTION of continuously varying prices. A simplified "binomial" version of the theory was subsequently developed by Sharpe *et al.* (1995) and Cox *et al.* (1979). It reproduces many results of the full-blown theory, and allows approximation of options for which analytic solutions are not known (Price 1996).

**Black Spleenwort Fern**

see BARNESLEY'S FERN

**Blackman Function**

An APODIZATION FUNCTION given by

$$A(x) = 0.42 + 0.5 \cos\left(\frac{\pi x}{a}\right) + 0.08 \cos\left(\frac{2\pi x}{a}\right). \quad (1)$$

Its FULL WIDTH AT HALF MAXIMUM is 0.810957a. The APPARATUS FUNCTION is

$$I(k) = \frac{a(0.84 - 0.36a^2k^2 - 2.17 \times 10^{-19}a^4k^4) \sin(2\pi ak)}{(1 - a^2k^2)(1 - 4a^2k^2)}. \quad (2)$$

The COEFFICIENTS are approximations to

$$a_0 = \frac{3969}{9304} \quad (3)$$

$$a_1 = \frac{1155}{4652} \quad (4)$$

$$a_2 = \frac{715}{18608}, \quad (5)$$

which would have produced zeros of  $I(k)$  at  $k = (7/4)a$  and  $k = (9/4)a$ .

**Blancmange Function**

A CONTINUOUS FUNCTION which is nowhere DIFFERENTIABLE. The iterations towards the continuous function are BATRACHIONS resembling the HOFSTADTER-CONWAY \$10,000 SEQUENCE. The first six iterations are illustrated below. The  $d$ th iteration contains  $N + 1$

points, where  $N = 2^d$ , and can be obtained by setting  $b(0) = b(N) = 0$ , letting

$$b(m + 2^{n-1}) = 2^n + \frac{1}{2}[b(m) + b(m + 2^n)],$$

and looping over  $n = d$  to 1 by steps of  $-1$  and  $m = 0$  to  $N - 1$  by steps of  $2^n$ .

Peitgen and Saupe (1988) refer to this curve as the TAKAGI FRACTAL CURVE.

**Blichfeldt's Lemma**

see BLICHFELDT'S THEOREM

**Blichfeldt's Theorem**

Published in 1914 by Hans Blichfeldt. It states that any bounded planar region with POSITIVE AREA  $> A$  placed in any position of the UNIT SQUARE LATTICE can be TRANSLATED so that the number of LATTICE POINTS inside the region will be at least  $A + 1$ . The theorem can be generalized to  $n$ -D.

**BLM/Ho Polynomial**

A 1-variable unoriented KNOT POLYNOMIAL  $Q(x)$ . It satisfies

$$Q_{\text{unknot}} = 1 \quad (1)$$

and the SKEIN RELATIONSHIP

$$Q_{L_+} + Q_{L_-} = x(Q_{L_0} + Q_{L_\infty}). \quad (2)$$

It also satisfies

$$Q_{L_1 \# L_2} = Q_{L_1} Q_{L_2}, \quad (3)$$

where  $\#$  is the KNOT SUM and

$$Q_{L^*} = Q_L, \quad (4)$$

where  $L^*$  is the MIRROR IMAGE of  $L$ . The BLM/Ho polynomials of MUTANT KNOTS are also identical. Brandt *et al.* (1986) give a number of interesting properties. For any LINK  $L$  with  $\geq 2$  components,  $Q_L - 1$  is divisible by  $2(x - 1)$ . If  $L$  has  $c$  components, then the lowest POWER of  $x$  in  $Q_L(x)$  is  $1 - c$ , and

$$\lim_{x \rightarrow 0} x^{c-1} Q_L(x) = \lim_{(\ell, m) \rightarrow (1, 0)} (-m)^{c-1} P_L(\ell, m), \quad (5)$$

where  $P_L$  is the HOMFLY POLYNOMIAL. Also, the degree of  $Q_L$  is less than the CROSSING NUMBER of  $L$ . If  $L$  is a 2-BRIDGE KNOT, then

$$Q_L(z) = 2z^{-1} V_L(t) V_L(t^{-1} + 1 - 2z^{-1}), \quad (6)$$

where  $z \equiv -t - t^{-1}$  (Kanenobu and Sumi 1993).

The POLYNOMIAL was subsequently extended to the 2-variable KAUFFMAN POLYNOMIAL  $F(a, z)$ , which satisfies

$$Q(x) = F(1, x). \quad (7)$$

Brandt *et al.* (1986) give a listing of  $Q$  POLYNOMIALS for KNOTS up to 8 crossings and links up to 6 crossings.

**Bloch Constant**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let  $F$  be the set of COMPLEX analytic functions  $f$  defined on an open region containing the closure of the unit disk  $D = \{z : |z| < 1\}$  satisfying  $f(0) = 0$  and  $df/dz(0) = 1$ . For each  $f$  in  $F$ , let  $b(f)$  be the SUPREMUM of all numbers  $r$  such that there is a disk  $S$  in  $D$  on which  $f$  is ONE-TO-ONE and such that  $f(S)$  contains a disk of radius  $r$ . In 1925, Bloch (Conway 1978) showed that  $b(f) \geq 1/72$ . Define Bloch's constant by

$$B \equiv \inf\{b(f) : f \in F\}.$$

Ahlfors and Grunsky (1937) derived

$$0.433012701 \dots = \frac{1}{4}\sqrt{3} \leq B \\ < \frac{1}{\sqrt{1+\sqrt{3}}} \frac{\Gamma(\frac{1}{3})\Gamma(\frac{11}{12})}{\Gamma(\frac{1}{4})} < 0.4718617.$$

They also conjectured that the upper limit is actually the value of  $B$ ,

$$B = \frac{1}{\sqrt{1+\sqrt{3}}} \frac{\Gamma(\frac{1}{3})\Gamma(\frac{11}{12})}{\Gamma(\frac{1}{4})} \\ = \sqrt{\pi} 2^{1/4} \frac{\Gamma(\frac{1}{3})}{\Gamma(\frac{1}{4})} \sqrt{\frac{\Gamma(\frac{11}{12})}{\Gamma(\frac{1}{12})}} \\ = 0.4718617 \dots$$

(Le Lionnais 1983).

**Bloch-Landau Constant**

see LANDAU CONSTANT

**Block**

see also BLOCK DESIGN, SQUARE POLYOMINO

**Block Design**

An incidence system  $(v, k, \lambda, r, b)$  in which a set  $X$  of  $v$  points is partitioned into a family  $A$  of  $b$  subsets (blocks) in such a way that any two points determine  $\lambda$  blocks, there are  $k$  points in each block, and each point is contained in  $r$  different blocks. It is also generally required that  $k < v$ , which is where the "incomplete" comes from in the formal term most often encountered

for block designs, BALANCED INCOMPLETE BLOCK DESIGNS (BIBD). The five parameters are not independent, but satisfy the two relations

$$vr = bk \quad (1)$$

$$\lambda(v-1) = r(k-1). \quad (2)$$

A BIBD is therefore commonly written as simply  $(v, k, \lambda)$ , since  $b$  and  $r$  are given in terms of  $v, k$ , and  $\lambda$  by

$$b = \frac{v(v-1)\lambda}{k(k-1)} \quad (3)$$

$$r = \frac{\lambda(v-1)}{k-1}. \quad (4)$$

A BIBD is called SYMMETRIC if  $b = v$  (or, equivalently,  $r = k$ ).

Writing  $X = \{x_i\}_{i=1}^v$  and  $A = \{A_j\}_{j=1}^b$ , then the INCIDENCE MATRIX of the BIBD is given by the  $v \times b$  MATRIX  $M$  defined by

$$m_{ij} = \begin{cases} 1 & \text{if } x_i \in A_j \\ 0 & \text{otherwise.} \end{cases} \quad (5)$$

This matrix satisfies the equation

$$MM^T = (r - \lambda)I + \lambda J, \quad (6)$$

where  $I$  is a  $v \times v$  IDENTITY MATRIX and  $J$  is a  $v \times v$  matrix of 1s (Dinitz and Stinson 1992).

Examples of BIBDs are given in the following table.

Block Design	$(v, k, \lambda)$
affine plane	$(n^2, n, 1)$
Fano plane	$(7, 3, 1)$
Hadamard design	symmetric $(4n+3, 2n+1, n)$
projective plane	symmetric $(n^2+n+1, n+1, 1)$
Steiner triple system	$(v, 3, 1)$
unital	$(q^3+1, q+1, 1)$

#### Block Growth

Let  $(x_0x_1x_2\ldots)$  be a sequence over a finite ALPHABET  $A$  (all the entries are elements of  $A$ ). Define the block growth function  $B(n)$  of a sequence to be the number of ADMISSIBLE words of length  $n$ . For example, in the sequence  $aabaabaabaabaab\ldots$ , the following words are ADMISSIBLE

Length	Admissible Words
1	$a, b$
2	$aa, ab, ba$
3	$aab, aba, baa$
4	$aaba, abaa, baab$

so  $B(1) = 2$ ,  $B(2) = 3$ ,  $B(3) = 3$ ,  $B(4) = 3$ , and so on. Notice that  $B(n) \leq B(n+1)$ , so the block growth function is always nondecreasing. This is because any ADMISSIBLE word of length  $n$  can be extended rightwards to produce an ADMISSIBLE word of length  $n+1$ . Moreover, suppose  $B(n) = B(n+1)$  for some  $n$ . Then each admissible word of length  $n$  extends to a *unique* ADMISSIBLE word of length  $n+1$ .

For a SEQUENCE in which each substring of length  $n$  uniquely determines the next symbol in the SEQUENCE, there are only finitely many strings of length  $n$ , so the process must eventually cycle and the SEQUENCE must be eventually periodic. This gives us the following theorems:

1. If the SEQUENCE is eventually periodic, with least period  $p$ , then  $B(n)$  is strictly increasing until it reaches  $p$ , and  $B(n)$  is constant thereafter.
2. If the SEQUENCE is not eventually periodic, then  $B(n)$  is strictly increasing and so  $B(n) \geq n+1$  for all  $n$ . If a SEQUENCE has the property that  $B(n) = n+1$  for all  $n$ , then it is said to have minimal block growth, and the SEQUENCE is called a STURMIAN SEQUENCE.

The block growth is also called the GROWTH FUNCTION or the COMPLEXITY of a SEQUENCE.

#### Block Matrix

A square DIAGONAL MATRIX in which the diagonal elements are SQUARE MATRICES of any size (possibly even  $1 \times 1$ ), and the off-diagonal elements are 0.

#### Block (Set)

One of the disjoint SUBSETS making up a SET PARTITION. A block containing  $n$  elements is called an  $n$ -block. The partitioning of sets into blocks can be denoted using a RESTRICTED GROWTH STRING.

see also BLOCK DESIGN, RESTRICTED GROWTH STRING, SET PARTITION

#### Blow-Up

A common mechanism which generates SINGULARITIES from smooth initial conditions.

**Blue-Empty Coloring**

see BLUE-EMPTY GRAPH

**Blue-Empty Graph**

AN EXTREMAL GRAPH in which the forced TRIANGLES are all the same color. Call  $R$  the number of red MONOCHROMATIC FORCED TRIANGLES and  $B$  the number of blue MONOCHROMATIC FORCED TRIANGLES, then a blue-empty graph is an EXTREMAL GRAPH with  $B = 0$ . For EVEN  $n$ , a blue-empty graph can be achieved by coloring red two COMPLETE SUBGRAPHS of  $n/2$  points (the RED NET method). There is no blue-empty coloring for ODD  $n$  except for  $n = 7$  (Lorden 1962).

see also COMPLETE GRAPH, EXTREMAL GRAPH, MONOCHROMATIC FORCED TRIANGLE, RED NET

**Bogomolov-Miyaoka-Yau Inequality**

Relates invariants of a curve defined over the INTEGERS. If this inequality were proven true, then FERMAT'S LAST THEOREM would follow for sufficiently large exponents. Miyaoka claimed to have proven this inequality in 1988, but the proof contained an error.

see also FERMAT'S LAST THEOREM

**References**

- Cox, D. A. "Introduction to Fermat's Last Theorem." *Amer. Math. Monthly* **101**, 3–14, 1994.

**Bohemian Dome**

A QUARTIC SURFACE which can be constructed as follows. Given a CIRCLE  $C$  and PLANE  $E$  PERPENDICULAR to the PLANE of  $C$ , move a second CIRCLE  $K$  of the same RADIUS as  $C$  through space so that its CENTER always lies on  $C$  and it remains PARALLEL to  $E$ . Then  $K$  sweeps out the Bohemian dome. It can be given by the parametric equations

$$\begin{aligned} x &= a \cos u \\ y &= b \cos v + a \sin u \\ z &= c \sin v \end{aligned}$$

where  $u, v \in [0, 2\pi)$ . In the above plot,  $a = 0.5$ ,  $b = 1.5$ , and  $c = 1$ .

see also QUARTIC SURFACE

## Bohr-Favard Inequalities

If  $f$  has no spectrum in  $[-\lambda, \lambda]$ , then

$$\|f\|_{\infty} \leq \frac{\pi}{2\lambda} \|f'\|_{\infty}$$

(Bohr 1935). A related inequality states that if  $A_k$  is the class of functions such that

$$f(x) = f(x + 2\pi), f(x), f'(x), \dots, f^{(k-1)}(x)$$

are absolutely continuous and  $\int_0^{2\pi} f(x) dx = 0$ , then

$$\|f\|_{\infty} \leq \frac{4}{\pi} \sum_{\nu=0}^{\infty} \frac{(-1)^{\nu(k+1)}}{(2\nu+1)^{k+1}} \|f^{(k)}(x)\|_{\infty}$$

(Northcott 1939). Further, for each value of  $k$ , there is always a function  $f(x)$  belonging to  $A_k$  and not identically zero, for which the above inequality becomes an inequality (Favard 1936). These inequalities are discussed in Mitrinovic *et al.* (1991).

## Bolzano Theorem

see BOLZANO-WEIERSTRASS THEOREM

## Bolzano-Weierstraß Theorem

Every BOUNDED infinite set in  $\mathbb{R}^n$  has an ACCUMULATION POINT. For  $n = 1$ , the theorem can be stated as follows: If a SET in a METRIC SPACE, finite-dimensional EUCLIDEAN SPACE, or FIRST-COUNTABLE SPACE has infinitely many members within a finite interval  $x \in [a, b]$ , then it has at least one LIMIT POINT  $x$  such that  $x \in [a, b]$ . The theorem can be used to prove the INTERMEDIATE VALUE THEOREM.

## Bombieri's Inequality

For HOMOGENEOUS POLYNOMIALS  $P$  and  $Q$  of degree  $m$  and  $n$ , then

$$[P \cdot Q]_2 \geq \sqrt{\frac{m!n!}{(m+n)!}} [P]_2 [Q]_2,$$

where  $[P \cdot Q]_2$  is the BOMBIERI NORM. If  $m = n$ , this becomes

$$[P \cdot Q]_2 \geq [P]_2 [Q]_2.$$

see also BEAUZAMY AND DÉGOT'S IDENTITY, REZNIK'S IDENTITY

## Bombieri Inner Product

For HOMOGENEOUS POLYNOMIALS  $P$  and  $Q$  of degree  $n$ ,

$$[P, Q] \equiv \sum_{i_1, \dots, i_n \geq 0} (i_1! \cdots i_n!) (a_{i_1, \dots, i_n} b_{i_1, \dots, i_n}).$$

## Bombieri Norm

For HOMOGENEOUS POLYNOMIALS  $P$  of degree  $m$ ,

$$[P]_2 \equiv \sqrt{[P, P]} = \left( \sum_{|\alpha|=m} \frac{\alpha!}{m!} |a_{\alpha}|^2 \right)^{1/2}.$$

see also POLYNOMIAL BAR NORM

**Bombieri's Theorem**

Define

$$E(x; q, a) \equiv \psi(x; q, a) - \frac{x}{\phi(q)}, \quad (1)$$

where

$$\psi(x; q, a) = \sum_{\substack{n \leq x \\ n \equiv a \pmod{q}}} \Lambda(n) \quad (2)$$

(Davenport 1980, p. 121),  $\Lambda(n)$  is the MANGOLDT FUNCTION, and  $\phi(q)$  is the TOTIENT FUNCTION. Now define

$$E(x; q) = \max_{(a, q)=1} |E(x; q, a)| \quad (3)$$

where the sum is over  $a$  RELATIVELY PRIME to  $q$ ,  $(a, q) = 1$ , and

$$E^*(x, q) = \max_{y \leq x} E(y, q). \quad (4)$$

Bombieri's theorem then says that for  $A > 0$  fixed,

$$\sum_{q \leq Q} E^*(x, q) \ll \sqrt{x} Q (\ln x)^5, \quad (5)$$

provided that  $\sqrt{x} (\ln x)^{-4} \leq Q \leq \sqrt{x}$ .

**Bond Percolation**

bond percolation

site percolation

A PERCOLATION which considers the lattice edges as the relevant entities (left figure).

see also PERCOLATION THEORY, SITE PERCOLATION

**Bonferroni Correction**

The Bonferroni correction is a multiple-comparison correction used when several independent STATISTICAL TESTS are being performed simultaneously (since while a given ALPHA VALUE  $\alpha$  may be appropriate for each individual comparison, it is not for the set of *all* comparisons). In order to avoid a lot of spurious positives, the ALPHA VALUE needs to be lowered to account for the number of comparisons being performed.

The simplest and most conservative approach is the Bonferroni correction, which sets the ALPHA VALUE for the entire *set* of  $n$  comparisons equal to  $\alpha$  by taking the

ALPHA VALUE for *each* comparison equal to  $\alpha/n$ . Explicitly, given  $n$  tests  $T_i$  for hypotheses  $H_i$  ( $1 \leq i \leq n$ ) under the assumption  $H_0$  that all hypotheses  $H_i$  are false, and if the individual test critical values are  $\leq \alpha/n$ , then the experiment-wide critical value is  $\leq \alpha$ . In equation form, if

$$P(T_i \text{ passes} | H_0) \leq \frac{\alpha}{n}$$

for  $1 \leq i \leq n$ , then

$$P(\text{some } T_i \text{ passes} | H_0) \leq \alpha,$$

which follows from BONFERRONI'S INEQUALITY.

Another correction instead uses  $1 - (1 - \alpha)^{1/n}$ . While this choice is applicable for two-sided hypotheses, multivariate normal statistics, and positive orthant dependent statistics, it is not, in general, correct (Shaffer 1995).

**Bonferroni's Inequality**

Let  $P(E_i)$  be the probability that  $E_i$  is true, and  $P(\bigcup_{i=1}^n E_i)$  be the probability that  $E_1, E_2, \dots, E_n$  are all true. Then

$$P\left(\bigcup_{i=1}^n E_i\right) \leq \sum_{i=1}^n P(E_i).$$

**Bonferroni Test**

see BONFERRONI CORRECTION

**Bonne Projection**

A MAP PROJECTION which resembles the shape of a heart. Let  $\phi_1$  be the standard parallel and  $\lambda_0$  the central meridian. Then

$$x = \rho \sin E \quad (1)$$

$$y = R \cot \phi_1 - \rho \cos R, \quad (2)$$

where

$$\rho = \cot \phi_1 + \phi_1 - \phi \quad (3)$$

$$E = \frac{(\lambda - \lambda_0) \cos \phi}{\rho}. \quad (4)$$

The inverse FORMULAS are

$$\phi = \cot \phi_1 + \phi_1 - \rho \quad (5)$$

$$\lambda = \lambda_0 + \frac{\rho}{\cos \phi} \tan^{-1} \left( \frac{x}{\cot \phi_1 - y} \right), \quad (6)$$

where

$$\rho = \pm \sqrt{x^2 + (\cot \phi_1 - y)^2}. \quad (7)$$

#### Book Stacking Problem

How far can a stack of  $n$  books protrude over the edge of a table without the stack falling over? It turns out that the maximum overhang possible  $d_n$  for  $n$  books (in terms of book lengths) is half the  $n$ th partial sum of the HARMONIC SERIES, given explicitly by

$$d_n = \frac{1}{2} \sum_{k=1}^n \frac{1}{k} = \frac{1}{2} [\gamma + \Psi(1+n)]$$

where  $\Psi(z)$  is the DIGAMMA FUNCTION and  $\gamma$  is the EULER-MASCHERONI CONSTANT. The first few values are

$$d_1 = \frac{1}{2} = 0.5$$

$$d_2 = \frac{3}{4} = 0.75$$

$$d_3 = \frac{11}{12} \approx 0.91667$$

$$d_4 = \frac{25}{24} \approx 1.04167,$$

(Sloane's A001008 and A002805).

In order to find the number of stacked books required to obtain  $d$  book-lengths of overhang, solve the  $d_n$  equation for  $d$ , and take the CEILING FUNCTION. For  $n = 1, 2, \dots$  book-lengths of overhang, 4, 31, 227, 1674, 12367, 91380, 675214, 4989191, 36865412, 272400600, ... (Sloane's A014537) books are needed.

#### Boole's Inequality

$$P \left( \bigcup_{i=1}^N E_i \right) \leq \sum_{i=1}^N P(E_i).$$

If  $E_i$  and  $E_j$  are MUTUALLY EXCLUSIVE for all  $i$  and  $j$ , then the INEQUALITY becomes an equality.

#### Boolean Algebra

A mathematical object which is similar to a BOOLEAN RING, but which uses the meet and join operators instead of the usual addition and multiplication operators. A Boolean algebra is a set  $B$  of elements  $a, b, \dots$  with BINARY OPERATORS  $+$  and  $\cdot$  such that

- 1a. If  $a$  and  $b$  are in the set  $B$ , then  $a + b$  is in the set  $B$ .
- 1b. If  $a$  and  $b$  are in the set  $B$ , then  $a \cdot b$  is in the set  $B$ .
- 2a. There is an element  $Z$  (zero) such that  $a + Z = a$  for every element  $a$ .
- 2b. There is an element  $U$  (unity) such that  $a \cdot U = a$  for every element  $a$ .
- 3a.  $a + b = b + a$
- 3b.  $a \cdot b = b \cdot a$
- 4a.  $a + b \cdot c = (a + b)(a + c)$
- 4b.  $a \cdot (b + c) = a \cdot b + a \cdot c$
5. For every element  $a$  there is an element  $a'$  such that  $a + a' = U$  and  $a \cdot a' = Z$ .
6. There are at least two distinct elements in the set  $B$ .

(Bell 1937, p. 444).

In more modern terms, a Boolean algebra is a SET  $B$  of elements  $a, b, \dots$  with the following properties:

1.  $B$  has two binary operations,  $\wedge$  (WEDGE) and  $\vee$  (VEE), which satisfy the IDEMPOTENT laws

$$a \wedge a = a \vee a = a,$$

the COMMUTATIVE laws

$$a \wedge b = b \wedge a$$

$$a \vee b = b \vee a,$$

and the ASSOCIATIVE laws

$$a \wedge (b \wedge c) = (a \wedge b) \wedge c$$

$$a \vee (b \vee c) = (a \vee b) \vee c.$$

2. The operations satisfy the ABSORPTION LAW

$$a \wedge (a \vee b) = a \vee (a \wedge b) = a.$$

3. The operations are mutually distributive

$$a \wedge (b \vee c) = (a \wedge b) \vee (a \wedge c)$$

$$a \vee (b \wedge c) = (a \vee b) \wedge (a \vee c).$$

4.  $B$  contains universal bounds  $O, I$  which satisfy

$$O \wedge a = O$$

$$O \vee a = a$$

$$I \wedge a = a$$

$$I \vee a = I.$$

5.  $B$  has a unary operation  $a \rightarrow a'$  of complementation which obeys the laws

$$a \wedge a' = O$$

$$a \vee a' = I$$

(Birkhoff and Mac Lane 1965). Under intersection, union, and complement, the subsets of any set  $I$  form a Boolean algebra.

Huntington (1933a, b) presented the following basis for Boolean algebra,

1. Commutivity.  $x + y = y + x$ .
2. Associativity.  $(x + y) + z = x + (y + z)$ .
3. HUNTINGTON EQUATION.  $n(n(x) + y) + n(n(x) + n(y)) = x$ .

H. Robbins then conjectured that the HUNTINGTON EQUATION could be replaced with the simpler ROBBINS EQUATION,

$$n(n(x + y) + n(x + n(y))) = x.$$

The ALGEBRA defined by commutivity, associativity, and the ROBBINS EQUATION is called ROBBINS ALGEBRA. Computer theorem proving demonstrated that every ROBBINS ALGEBRA satisfies the second WINKLER CONDITION, from which it follows immediately that all ROBBINS ALGEBRAS are Boolean.

#### Boolean Connective

One of the LOGIC operators AND  $\wedge$ , OR  $\vee$ , and NOT  $\neg$ .  
see also QUANTIFIER

#### Boolean Function

A Boolean function in  $n$  variables is a function

$$f(x_1, \dots, x_n),$$

where each  $x_i$  can be 0 or 1 and  $f$  is 0 or 1. Determining the number of monotone Boolean functions of  $n$  variables is known as DEDEKIND'S PROBLEM. The number of monotonic increasing Boolean functions of  $n$  variables is given by 2, 3, 6, 20, 168, 7581, 7828354, ... (Sloane's A000372, Beeler *et al.* 1972, Item 17). The number of inequivalent monotone Boolean functions of  $n$  variables is given by 2, 3, 5, 10, 30, ... (Sloane's A003182).

Let  $M(n, k)$  denote the number of distinct monotone Boolean functions of  $n$  variables with  $k$  mincuts. Then

$$M(n, 0) = 1$$

$$M(n, 1) = 2^n$$

$$M(n, 2) = 2^{n-1}(2^n - 1) - 3^n + 2^n$$

$$M(n, 3) = \frac{1}{6}(2^n)(2^n - 1)(2^n - 2) - 6^n + 5^n + 4^n - 3^n.$$

## Bordism

A relation between COMPACT boundaryless MANIFOLDS (also called closed MANIFOLDS). Two closed MANIFOLDS are bordant IFF their disjoint union is the boundary of a compact  $(n+1)$ -MANIFOLD. Roughly, two MANIFOLDS are bordant if together they form the boundary of a MANIFOLD. The word bordism is now used in place of the original term COBORDISM.

## References

Budney, R. "The Bordism Project." <http://math.cornell.edu/~rybu/bordism/bordism.html>.

## Bordism Group

There are bordism groups, also called COBORDISM GROUPS or COBORDISM RINGS, and there are singular bordism groups. The bordism groups give a framework for getting a grip on the question, "When is a compact boundaryless MANIFOLD the boundary of another MANIFOLD?" The answer is, precisely when all of its STIEFEL-WHITNEY CLASSES are zero. Singular bordism groups give insight into STEENROD'S REALIZATION PROBLEM: "When can homology classes be realized as the image of fundamental classes of manifolds?" That answer is known, too.

The machinery of the bordism group winds up being important for HOMOTOPY THEORY as well.

## References

Budney, R. "The Bordism Project." <http://math.cornell.edu/~rybu/bordism/bordism.html>.

## Borel-Cantelli Lemma

Let  $\{A_n\}_{n=0}^{\infty}$  be a SEQUENCE of events occurring with a certain probability distribution, and let  $A$  be the event consisting of the occurrence of a finite number of events  $A_n$ ,  $n = 1, \dots$ . Then if

$$\sum_{n=1}^{\infty} P(A_n) < \infty,$$

then

$$P(A) = 1.$$

## Borel Determinacy Theorem

Let  $T$  be a tree defined on a metric over a set of paths such that the distance between paths  $p$  and  $q$  is  $1/n$ , where  $n$  is the number of nodes shared by  $p$  and  $q$ . Let  $A$  be a Borel set of paths in the topology induced by this metric. Suppose two players play a game by choosing a path down the tree, so that they alternate and each time choose an immediate successor of the previously chosen point. The first player wins if the chosen path is in  $A$ . Then one of the players has a winning STRATEGY in this GAME.

see also GAME THEORY, STRATEGY

## Borel's Expansion

Let  $\phi(t) = \sum_{n=0}^{\infty} A_n t^n$  be any function for which the integral

$$I(x) \equiv \int_0^{\infty} e^{-tx} t^p \phi(t) dt$$

converges. Then the expansion

$$I(x) = \frac{\Gamma(p+1)}{x^{p+1}} \left[ A_0 + (p+1) \frac{A_1}{x} + (p+1)(p+2) \frac{A_2}{x^2} + \dots \right],$$

where  $\Gamma(z)$  is the GAMMA FUNCTION, is usually an ASYMPTOTIC SERIES for  $I(x)$ .

## Borel Measure

If  $F$  is the BOREL SIGMA ALGEBRA on some TOPOLOGICAL SPACE, then a MEASURE  $m : F \rightarrow \mathbb{R}$  is said to be a Borel measure (or BOREL PROBABILITY MEASURE). For a Borel measure, all continuous functions are MEASURABLE.

## Borel Probability Measure

see BOREL MEASURE

**Borel Set**

A DEFINABLE SET derived from the REAL LINE by removing a FINITE number of intervals. Borel sets are measurable and constitute a special type of SIGMA ALGEBRA called a BOREL SIGMA ALGEBRA.

see also STANDARD SPACE

**Borel Sigma Algebra**

A SIGMA ALGEBRA which is related to the TOPOLOGY of a SET. The Borel *sigma*-algebra is defined to be the SIGMA ALGEBRA generated by the OPEN SETS (or equivalently, by the CLOSED SETS).

see also BOREL MEASURE

**Borel Space**

A SET equipped with a SIGMA ALGEBRA of SUBSETS.

**Borromean Rings**

Three mutually interlocked rings named after the Italian Renaissance family who used them on their coat of arms. No two rings are linked, so if one of the rings is cut, all three rings fall apart. They are given the LINK symbol  $06_{03}^{02}$ , and are also called the BALLANTINE. The Borromean rings have BRAID WORD  $\sigma_1^{-1}\sigma_2\sigma_1^{-1}\sigma_2\sigma_1^{-1}\sigma_2$  and are also the simplest BRUNNIAN LINK.

 \end{array}$$

borrows

The procedure used in SUBTRACTION to "borrow" 10 from the next higher DIGIT column in order to obtain a POSITIVE DIFFERENCE in the column in question.

see also CARRY

**Borsuk's Conjecture**

Borsuk conjectured that it is possible to cut an  $n$ -D shape of DIAMETER 1 into  $n + 1$  pieces each with diameter smaller than the original. It is true for  $n = 2, 3$  and when the boundary is "smooth." However, the minimum number of pieces required has been shown to increase as  $\sim 1.1\sqrt{n}$ . Since  $1.1\sqrt{n} > n + 1$  at  $n = 9162$ , the conjecture becomes false at high dimensions. In fact, the limit has been pushed back to  $\sim 2000$ .

**Borwein Conjectures**

Use the definition of the  $q$ -SERIES

$$(a; q)_n \equiv \prod_{j=0}^{n-1} (1 - aq^j) \quad (1)$$

and define

$$\left[ \begin{matrix} N \\ M \end{matrix} \right] \equiv \frac{(q^{N-M+1}; q)_M}{(q; q)_m}. \quad (2)$$

Then P. Borwein has conjectured that (1) the POLYNOMIALS  $A_n(q)$ ,  $B_n(q)$ , and  $C_n(q)$  defined by

$$(q; q^3)_n (q^2; q^3)_n = A_n(q^3) - qB_n(q^3) - q^2C_n(q^3) \quad (3)$$

have NONNEGATIVE COEFFICIENTS, (2) the POLYNOMIALS  $A_n^*(q)$ ,  $B_n^*(q)$ , and  $C_n^*(q)$  defined by

$$(q; q^3)_n^2 (q^2; q^3)_n^2 = A_n^*(q^3) - qB_n^*(q^3) - q^2C_n^*(q^3) \quad (4)$$

have NONNEGATIVE COEFFICIENTS, (3) the POLYNOMIALS  $A_n^*(q)$ ,  $B_n^*(q)$ ,  $C_n^*(q)$ ,  $D_n^*(q)$ , and  $E_n^*(q)$  defined by

$$(q; q^5)_n (q^2; q^5)_n (q^3; q^5)_n (q^4; q^5)_n = A_n^*(q^5) - qB_n^*(q^5) - q^2C_n^*(q^5) - q^3D_n^*(q^5) - q^4E_n^*(q^5) \quad (5)$$

have NONNEGATIVE COEFFICIENTS, (4) the POLYNOMIALS  $A_n^\dagger(m, n, t, q)$ ,  $B_n^\dagger(m, n, t, q)$ , and  $C_n^\dagger(m, n, t, q)$  defined by

$$(q; q^3)_m (q^2; q^3)_m (zq; q^3)_n (zq^2; q^3)_n \\ = \sum_{t=0}^{2m} z^t [A^\dagger(m, n, t, q^3) - qB^\dagger(m, n, t, q^3) \\ - q^2C^\dagger(m, n, t, q^3)] \quad (6)$$

have NONNEGATIVE COEFFICIENTS, (5) for  $k$  ODD and  $1 \leq a \leq k/2$ , consider the expansion

$$(q^a; q^k)_m (q^{k-a}; q^k)_n \\ = \sum_{\nu=(1-k)/2}^{(k-1)/2} (-1)^\nu q^{k(\nu^2+\nu)/2 - a\nu} F_\nu(q^k) \quad (7)$$

with

$$F_\nu(q) \\ = \sum_{j=-\infty}^{\infty} (-1)^j q^{j(k^2j+2k\nu+k-2a)/2} \begin{bmatrix} m+n \\ m+\nu+kj \end{bmatrix}, \quad (8)$$

then if  $a$  is RELATIVELY PRIME to  $k$  and  $m = n$ , the COEFFICIENTS of  $F_\nu(q)$  are NONNEGATIVE, and (6) given  $\alpha + \beta < 2K$  and  $-K + \beta \leq n - m \leq K - \alpha$ , consider

$$G(\alpha, \beta, K; q) = \sum_q (-1)^j q^{j[K(\alpha+\beta)j+K(\alpha+\beta)]/2} \\ \times \begin{bmatrix} m+n \\ m+Kj \end{bmatrix}, \quad (9)$$

the GENERATING FUNCTION for partitions inside an  $m \times n$  rectangle with hook difference conditions specified by  $\alpha$ ,  $\beta$ , and  $K$ . Let  $\alpha$  and  $\beta$  be POSITIVE RATIONAL NUMBERS and  $K > 1$  an INTEGER such that  $\alpha K$  and  $\beta K$  are integers. Then if  $1 \leq \alpha + \beta \leq 2K - 1$  (with strict inequalities for  $K = 2$ ) and  $-K + \beta \leq n - m \leq K - \alpha$ , then  $G(\alpha, \beta, K; q)$  has NONNEGATIVE COEFFICIENTS.

see also  $q$ -SERIES

### Bouligand Dimension

see MINKOWSKI-BOULIGAND DIMENSION

### Bound

see GREATEST LOWER BOUND, INFIMUM, LEAST UPPER BOUND, SUPREMUM

### Bound Variable

An occurrence of a variable in a LOGIC which is not FREE.

### Boundary

The set of points, known as BOUNDARY POINTS, which are members of the CLOSURE of a given set  $S$  and the CLOSURE of its complement set. The boundary is sometimes called the FRONTIER.

see also SURGERY

### Boundary Conditions

There are several types of boundary conditions commonly encountered in the solution of PARTIAL DIFFERENTIAL EQUATIONS.

1. DIRICHLET BOUNDARY CONDITIONS specify the value of the function on a surface  $T = f(\mathbf{r}, t)$ .
2. NEUMANN BOUNDARY CONDITIONS specify the normal derivative of the function on a surface,

$$\frac{\partial T}{\partial n} = \hat{\mathbf{n}} \cdot \nabla T = f(\mathbf{r}, y).$$

3. CAUCHY BOUNDARY CONDITIONS specify a weighted average of first and second kinds.
4. ROBIN BOUNDARY CONDITIONS. For an elliptic partial differential equation in a region  $\Omega$ , Robin boundary conditions specify the sum of  $\alpha u$  and the normal derivative of  $u = f$  at all points of the boundary of  $\Omega$ , with  $\alpha$  and  $f$  being prescribed.

see also BOUNDARY VALUE PROBLEM, DIRICHLET BOUNDARY CONDITIONS, INITIAL VALUE PROBLEM, NEUMANN BOUNDARY CONDITIONS, PARTIAL DIFFERENTIAL EQUATION, ROBIN BOUNDARY CONDITIONS

### Boundary Map

The MAP  $H_n(X, A) \rightarrow H_{n-1}(A)$  appearing in the LONG EXACT SEQUENCE OF A PAIR AXIOM.

see also LONG EXACT SEQUENCE OF A PAIR AXIOM

### Boundary Point

A point which is a member of the CLOSURE of a given set  $S$  and the CLOSURE of its complement set. If  $A$  is a subset of  $\mathbb{R}^n$ , then a point  $\mathbf{x} \in \mathbb{R}^n$  is a boundary point of  $A$  if every NEIGHBORHOOD of  $\mathbf{x}$  contains at least one point in  $A$  and at least one point not in  $A$ .

see also BOUNDARY

**Boundary Set**

A (symmetrical) boundary set of RADIUS  $r$  and center  $\mathbf{x}_0$  is the set of all points  $\mathbf{x}$  such that

$$|\mathbf{x} - \mathbf{x}_0| = r.$$

Let  $\mathbf{x}_0$  be the ORIGIN. In  $\mathbb{R}^1$ , the boundary set is then the pair of points  $x = r$  and  $x = -r$ . In  $\mathbb{R}^2$ , the boundary set is a CIRCLE. In  $\mathbb{R}^3$ , the boundary set is a SPHERE.

see also CIRCLE, DISK, OPEN SET, SPHERE

**Boundary Value Problem**

A boundary value problem is a problem, typically an ORDINARY DIFFERENTIAL EQUATION or a PARTIAL DIFFERENTIAL EQUATION, which has values assigned on the physical boundary of the DOMAIN in which the problem is specified. For example,

$$\begin{cases} \frac{\partial^2 u}{\partial t^2} - \nabla^2 u = f & \text{in } \Omega \\ u(0, t) = u_1 & \text{on } \partial\Omega \\ \frac{\partial u}{\partial t}(0, t) = u_2 & \text{on } \partial\Omega, \end{cases}$$

where  $\partial\Omega$  denotes the boundary of  $\Omega$ , is a boundary problem.

see also BOUNDARY CONDITIONS, INITIAL VALUE PROBLEM

**Bounded**

A SET in a METRIC SPACE  $(X, d)$  is bounded if it has a FINITE diameter, i.e., there is an  $R < \infty$  such that  $d(x, y) \leq R$  for all  $x, y \in X$ . A SET in  $\mathbb{R}^n$  is bounded if it is contained inside some BALL  $x_1^2 + \dots + x_n^2 \leq R^2$  of FINITE RADIUS  $R$  (Adams 1994).

see also BOUND, FINITE

**Bounded Variation**

A FUNCTION  $f(x)$  is said to have bounded variation if, over the CLOSED INTERVAL  $x \in [a, b]$ , there exists an  $M$  such that

$$|f(x_i) - f(a)| + |f(x_2) - f(x_1)| + \dots + |f(b) - f(x_{n-1})| \leq M$$

for all  $a < x_1 < x_2 < \dots < x_{n-1} < b$ .

**Bourget Function**

$$\begin{aligned} J_{n,k}(z) &= \frac{1}{\pi i} \int t^{-n-1} \left(t + \frac{1}{t}\right)^k \exp\left[\frac{1}{2}z\left(t - \frac{1}{t}\right)\right] dt \\ &= \frac{1}{\pi} \int_0^\pi (2 \cos \theta)^k \cos(n\theta - z \sin \theta) d\theta. \end{aligned}$$

**Boustrophedon Transform**

The boustrophedon ("ox-plowing") transform  $\mathbf{b}$  of a sequence  $\mathbf{a}$  is given by

$$b_n = \sum_{k=0}^n \binom{n}{k} a_k E_{n-k} \quad (1)$$

$$a_n = \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} b_k E_{n-k} \quad (2)$$

for  $n \geq 0$ , where  $E_n$  is a SECANT NUMBER or TANGENT NUMBER defined by

$$\sum_{n=0}^{\infty} E_n \frac{x^n}{n!} = \sec x + \tan x. \quad (3)$$

The exponential generating functions of  $\mathbf{a}$  and  $\mathbf{b}$  are related by

$$\mathcal{B}(x) = (\sec x + \tan x) \mathcal{A}(x), \quad (4)$$

where the exponential generating function is defined by

$$\mathcal{A}(x) = \sum_{n=0}^{\infty} A_n \frac{x^n}{n!}. \quad (5)$$

**Bowley Skewness**

Also known as QUARTILE SKEWNESS COEFFICIENT,

$$\frac{(Q_3 - Q_2) - (Q_2 - Q_1)}{Q_3 - Q_1} = \frac{Q_1 - 2Q_2 + Q_3}{Q_3 - Q_1},$$

where the  $Q$ s denote the INTERQUARTILE RANGES.

see also SKEWNESS

**Bowling**

Bowling is a game played by rolling a heavy ball down a long narrow track and attempting to knock down ten pins arranged in the form of a TRIANGLE with its vertex oriented towards the bowler. The number 10 is, in fact, the TRIANGULAR NUMBER  $T_4 = 4(4+1)/2 = 10$ .

Two "bowls" are allowed per "frame." If all the pins are knocked down in the two bowls, the score for that frame is the number of pins knocked down. If some or none of the pins are knocked down on the first bowl, then all the pins knocked down on the second, it is called a "spare," and the number of points tallied is 10 plus the number of pins knocked down on the bowl of the next frame. If all of the pins are knocked down on the first bowl, the number of points tallied is 10 plus the number of

pins knocked down on the next two bowls. Ten frames are bowled, unless the last frame is a strike or spare, in which case an additional bowl is awarded.

The maximum number of points possible, corresponding to knocking down all 10 pins on every bowl, is 300.

**Box**

see CUBOID

**Box-and-Whisker Plot**

A HISTOGRAM-like method of displaying data invented by J. Tukey (1977). Draw a box with ends at the QUARTILES  $Q_1$  and  $Q_3$ . Draw the MEDIAN as a horizontal line in the box. Extend the "whiskers" to the farthest points. For every point that is more than  $3/2$  times the INTERQUARTILE RANGE from the end of a box, draw a dot on the corresponding top or bottom of the whisker. If two dots have the same value, draw them side by side.

**References**

**Box Counting Dimension**

see CAPACITY DIMENSION

**Box Fractal**

A FRACTAL which can be constructed using STRING REWRITING by creating a matrix with 3 times as many entries as the current matrix using the rules

```
line 1: "*" -> "*" *, " " -> " "
line 2: "*" -> " * ", " " -> " "
line 3: "*" -> "*" *, " " -> " "
```

Let  $N_n$  be the number of black boxes,  $L_n$  the length of a side of a white box, and  $A_n$  the fractional AREA of black boxes after the  $n$ th iteration.

$$N_n = 5^n \quad (1)$$

$$L_n = \left(\frac{1}{3}\right)^n = 3^{-n} \quad (2)$$

$$A_n = L_n^2 N_n = \left(\frac{5}{9}\right)^n. \quad (3)$$

The CAPACITY DIMENSION is therefore

$$\begin{aligned} d_{\text{cap}} &= - \lim_{n \rightarrow \infty} \frac{\ln N_n}{\ln L_n} = - \lim_{n \rightarrow \infty} \frac{\ln(5^n)}{\ln(3^{-n})} \\ &= \frac{\ln 5}{\ln 3} = 1.464973521 \dots \end{aligned} \quad (4)$$

### Box-Muller Transformation

A transformation which transforms from a 2-D continuous UNIFORM DISTRIBUTION to a 2-D GAUSSIAN BIVARIATE DISTRIBUTION (or COMPLEX GAUSSIAN DISTRIBUTION). If  $x_1$  and  $x_2$  are uniformly and independently distributed between 0 and 1, then  $z_1$  and  $z_2$  as defined below have a GAUSSIAN DISTRIBUTION with MEAN  $\mu = 0$  and VARIANCE  $\sigma^2 = 1$ .

$$z_1 = \sqrt{-2 \ln x_1} \cos(2\pi x_2) \quad (1)$$

$$z_2 = \sqrt{-2 \ln x_1} \sin(2\pi x_2). \quad (2)$$

This can be verified by solving for  $x_1$  and  $x_2$ ,

$$x_1 = e^{-(z_1^2 + z_2^2)/2} \quad (3)$$

$$x_2 = \frac{1}{2\pi} \tan^{-1} \left( \frac{z_2}{z_1} \right). \quad (4)$$

Taking the JACOBIAN yields

$$\begin{aligned} \frac{\partial(x_1, x_2)}{\partial(z_1, z_2)} &= \begin{vmatrix} \frac{\partial x_1}{\partial z_1} & \frac{\partial x_1}{\partial z_2} \\ \frac{\partial x_2}{\partial z_1} & \frac{\partial x_2}{\partial z_2} \end{vmatrix} \\ &= - \left[ \frac{1}{\sqrt{2\pi}} e^{-z_1^2/2} \right] \left[ \frac{1}{\sqrt{2\pi}} e^{-z_2^2/2} \right]. \end{aligned} \quad (5)$$

### Box-Packing Theorem

The number of "prime" boxes is always finite, where a set of boxes is prime if it cannot be built up from one or more given configurations of boxes.

### Boy Surface

A NONORIENTABLE SURFACE which is one of the three possible SURFACES obtained by sewing a MÖBIUS STRIP to the edge of a DISK. The other two are the CROSS-CAP and ROMAN SURFACE. The Boy surface is a model of the PROJECTIVE PLANE without singularities and is a SEXTIC SURFACE.

The Boy surface can be described using the general method for NONORIENTABLE SURFACES, but this was not known until the analytic equations were found by Apéry (1986). Based on the fact that it had been proven impossible to describe the surface using quadratic polynomials, Hopf had conjectured that quartic polynomials were also insufficient (Pinkall 1986). Apéry's IMMERSION proved this conjecture wrong, giving the equations explicitly in terms of the standard form for a NONORIENTABLE SURFACE,

$$\begin{aligned} f_1(x, y, z) &= \frac{1}{2}[(2x^2 - y^2 - z^2)(x^2 + y^2 + z^2) \\ &\quad + 2yz(y^2 - z^2) + zx(x^2 - z^2) \\ &\quad + xy(y^2 - x^2)] \end{aligned} \quad (1)$$

$$\begin{aligned} f_2(x, y, z) &= \frac{1}{2}\sqrt{3}[(y^2 - z^2)(x^2 + y^2 + z^2) \\ &\quad + zx(z^2 - x^2) + xy(y^2 - x^2)] \end{aligned} \quad (2)$$

$$\begin{aligned} f_3(x, y, z) &= \frac{1}{8}(x + y + z)[(x + y + z)^3 \\ &\quad + 4(y - x)(z - y)(x - z)]. \end{aligned} \quad (3)$$

Plugging in

$$x = \cos u \sin v \quad (4)$$

$$y = \sin u \sin v \quad (5)$$

$$z = \cos v \quad (6)$$

and letting  $u \in [0, \pi]$  and  $v \in [0, \pi]$  then gives the Boy surface, three views of which are shown above.

The  $\mathbb{R}^3$  parameterization can also be written as

$$x = \frac{\sqrt{2} \cos^2 v \cos(2u) + \cos u \sin(2v)}{2 - \sqrt{2} \sin(3u) \sin(2v)} \quad (7)$$

$$y = \frac{\sqrt{2} \cos^2 v \sin(2u) + \cos u \sin(2v)}{2 - \sqrt{2} \sin(3u) \sin(2v)} \quad (8)$$

$$z = \frac{3 \cos^2 v}{2 - \sqrt{2} \sin(3u) \sin(2v)} \quad (9)$$

(Nordstrand) for  $u \in [-\pi/2, \pi/2]$  and  $v \in [0, \pi]$ .

Three views of the surface obtained using this parameterization are shown above.

In fact, a HOMOTOPY (smooth deformation) between the ROMAN SURFACE and Boy surface is given by the equations

$$x(u, v) = \frac{\sqrt{2} \cos(2u) \cos^2 v + \cos u \sin(2v)}{2 - \alpha \sqrt{2} \sin(3u) \sin(2v)} \quad (10)$$

$$y(u, v) = \frac{\sqrt{2} \sin(2u) \cos^2 v - \sin u \sin(2v)}{2 - \alpha \sqrt{2} \sin(3u) \sin(2v)} \quad (11)$$

$$z(u, v) = \frac{3 \cos^2 v}{2 - \alpha \sqrt{2} \sin(3u) \sin(2v)} \quad (12)$$

as  $\alpha$  varies from 0 to 1, where  $\alpha = 0$  corresponds to the ROMAN SURFACE and  $\alpha = 1$  to the Boy surface (Wang), shown below.

In  $\mathbb{R}^4$ , the parametric representation is

$$x_0 = 3[(u^2 + v^2 + w^2)(u^2 + v^2) - \sqrt{2}vw(3u^2 - v^2)] \quad (13)$$

$$x_1 = \sqrt{2}(u^2 + v^2)(u^2 - v^2 + \sqrt{2}uw) \quad (14)$$

$$x_2 = \sqrt{2}(u^2 + v^2)(2uv - \sqrt{2}vw) \quad (15)$$

$$x_3 = 3(u^2 + v^2)^2, \quad (16)$$

and the algebraic equation is

$$\begin{aligned} 64(x_0 - x_3)^3 x_3^3 - 48(x_0 - x_3)^2 x_3^2 (3x_1^2 + 3x_2^2 + 2x_3^2) \\ + 12(x_0 - x_3)x_3 [27(x_1^2 + x_2^2)^2 - 24x_3^2(x_1^2 + x_2^2) \\ + 36\sqrt{2}x_2x_3(x_2^2 - 3x_1^2) + x_3^4] \\ + (9x_1^2 + 9x_2^2 - 2x_3^2) \\ \times [-81(x_1^2 + x_2^2)^2 - 72x_3^2(x_1^2 + x_2^2) \\ + 108\sqrt{2}x_1x_3(x_1^2 - 3x_2^2) + 4x_3^4] = 0 \end{aligned} \quad (17)$$

(Apéry 1986). Letting

$$x_0 = 1 \quad (18)$$

$$x_1 = x \quad (19)$$

$$x_2 = y \quad (20)$$

$$x_3 = z \quad (21)$$

gives another version of the surface in  $\mathbb{R}^3$ .

**Bra**

A (COVARIANT) 1-VECTOR denoted  $\langle\psi|$ . The bra is DUAL to the CONTRAVARIANT KET, denoted  $|\psi\rangle$ . Taken together, the bra and KET form an ANGLE BRACKET (bra+ket = bracket). The bra is commonly encountered in quantum mechanics.

see also ANGLE BRACKET, BRACKET PRODUCT, COVARIANT VECTOR, DIFFERENTIAL  $k$ -FORM, KET, ONE-FORM

**Brachistochrone Problem**

Find the shape of the CURVE down which a bead sliding from rest and ACCELERATED by gravity will slip (without friction) from one point to another in the least time. This was one of the earliest problems posed in the CALCULUS OF VARIATIONS. The solution, a segment of a CYCLOID, was found by Leibniz, L'Hospital, Newton, and the two Bernoullis.

The time to travel from a point  $P_1$  to another point  $P_2$  is given by the INTEGRAL

$$t_{12} = \int_1^2 \frac{ds}{v}. \quad (1)$$

The VELOCITY at any point is given by a simple application of energy conservation equating kinetic energy to gravitational potential energy,

$$\frac{1}{2}mv^2 = mgy, \quad (2)$$

so

$$v = \sqrt{2gy}. \quad (3)$$

Plugging this into (1) then gives

$$t_{12} = \int_1^2 \frac{\sqrt{1+y'^2}}{\sqrt{2gy}} dx = \int_1^2 \sqrt{\frac{1+y'^2}{2gy}} dx. \quad (4)$$

The function to be varied is thus

$$f = (1+y'^2)^{1/2}(2gy)^{-1/2}. \quad (5)$$

To proceed, one would normally have to apply the full-blown EULER-LAGRANGE DIFFERENTIAL EQUATION

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \left( \frac{\partial f}{\partial y'} \right) = 0. \quad (6)$$

However, the function  $f(y, y', x)$  is particularly nice since  $x$  does not appear explicitly. Therefore,  $\partial f / \partial x = 0$ , and we can immediately use the BELTRAMI IDENTITY

$$f - y' \frac{\partial f}{\partial y'} = C. \quad (7)$$

Computing

$$\frac{\partial f}{\partial y'} = y'(1+y'^2)^{-1/2}(2gy)^{-1/2}, \quad (8)$$

**Brachistochrone Problem**

subtracting  $y'(\partial f / \partial y')$  from  $f$ , and simplifying then gives

$$\frac{1}{\sqrt{2gy}\sqrt{1+y'^2}} = C. \quad (9)$$

Squaring both sides and rearranging slightly results in

$$\left[ 1 + \left( \frac{dy}{dx} \right)^2 \right] y = \frac{1}{2gC^2} = k^2, \quad (10)$$

where the square of the old constant  $C$  has been expressed in terms of a new (POSITIVE) constant  $k^2$ . This equation is solved by the parametric equations

$$x = \frac{1}{2}k^2(\theta - \sin \theta) \quad (11)$$

$$y = \frac{1}{2}k^2(1 - \cos \theta), \quad (12)$$

which are—lo and behold—the equations of a CYCLOID.

If kinetic friction is included, the problem can also be solved analytically, although the solution is significantly messier. In that case, terms corresponding to the normal component of weight and the normal component of the ACCELERATION (present because of path CURVATURE) must be included. Including both terms requires a constrained variational technique (Ashby *et al.* 1975), but including the normal component of weight only gives an elementary solution. The TANGENT and NORMAL VECTORS are

$$\mathbf{T} = \frac{dx}{ds}\hat{\mathbf{x}} + \frac{dy}{ds}\hat{\mathbf{y}} \quad (13)$$

$$\mathbf{N} = -\frac{dy}{ds}\hat{\mathbf{x}} + \frac{dx}{ds}\hat{\mathbf{y}}, \quad (14)$$

gravity and friction are then

$$\mathbf{F}_{\text{gravity}} = mg\hat{\mathbf{y}} \quad (15)$$

$$\mathbf{F}_{\text{friction}} = -\mu(\mathbf{F}_{\text{gravity}}\cdot\hat{\mathbf{N}})\mathbf{T} = -\mu mg \frac{dx}{ds}\mathbf{T}, \quad (16)$$

and the components along the curve are

$$\mathbf{F}_{\text{gravity}}\cdot\hat{\mathbf{T}} = mg \frac{dy}{ds} \quad (17)$$

$$\mathbf{F}_{\text{friction}}\cdot\hat{\mathbf{T}} = -\mu mg \frac{dx}{ds}, \quad (18)$$

so Newton's Second Law gives

$$m \frac{dv}{dt} = mg \frac{dy}{ds} - \mu mg \frac{dx}{ds}. \quad (19)$$

But

$$\frac{dv}{dt} = v \frac{dv}{ds} = \frac{1}{2} \frac{d}{ds}(v^2) \quad (20)$$

$$\frac{1}{2}v^2 = g(y - \mu x) \quad (21)$$

$$v = \sqrt{2g(y - \mu x)}, \quad (22)$$

so

$$t = \int \sqrt{\frac{1 + (y')^2}{2g(y - \mu x)}} dx. \quad (23)$$

Using the EULER-LAGRANGE DIFFERENTIAL EQUATION gives

$$[1 + y'^2](1 + \mu y') + 2(y - \mu x)y'' = 0. \quad (24)$$

This can be reduced to

$$\frac{1 + (y')^2}{(1 + \mu y')^2} = \frac{C}{y - \mu x}. \quad (25)$$

Now letting

$$y' = \cot(\tfrac{1}{2}\theta), \quad (26)$$

the solution is

$$x = \tfrac{1}{2}k^2[(\theta - \sin \theta) + \mu(1 - \cos \theta)] \quad (27)$$

$$y = \tfrac{1}{2}k^2[(1 - \cos \theta) + \mu(\theta + \sin \theta)]. \quad (28)$$

## Bracket Polynomial

A one-variable KNOT POLYNOMIAL related to the JONES POLYNOMIAL. The bracket polynomial, however, is *not* a topological invariant, since it is changed by type I REIDEMEISTER MOVES. However, the SPAN of the bracket polynomial is a knot invariant. The bracket polynomial is occasionally given the grandiose name REGULAR ISOTOPY INVARIANT. It is defined by

$$\langle L \rangle (A, B, d) \equiv \sum_{\sigma} \langle L | \sigma \rangle d^{||\sigma||}, \quad (1)$$

where  $A$  and  $B$  are the "splitting variables,"  $\sigma$  runs through all "states" of  $L$  obtained by SPLITTING the LINK,  $\langle L | \sigma \rangle$  is the product of "splitting labels" corresponding to  $\sigma$ , and

$$||\sigma|| \equiv N_L - 1, \quad (2)$$

where  $N_L$  is the number of loops in  $\sigma$ . Letting

$$B = A^{-1} \quad (3)$$

$$d = -A^2 - A^{-2} \quad (4)$$

gives a KNOT POLYNOMIAL which is invariant under REGULAR ISOTOPY, and normalizing gives the KAUFFMAN POLYNOMIAL  $X$  which is invariant under AMBIENT ISOTOPY. The bracket POLYNOMIAL of the UNKNOT is 1. The bracket POLYNOMIAL of the MIRROR IMAGE  $K^*$  is the same as for  $K$  but with  $A$  replaced by  $A^{-1}$ . In terms of the one-variable KAUFFMAN POLYNOMIAL  $X$ , the two-variable KAUFFMAN POLYNOMIAL  $F$  and the JONES POLYNOMIAL  $V$ ,

$$X(A) = (-A^3)^{-w(L)} \langle L \rangle, \quad (5)$$

$$\langle L \rangle (A) = F(-A^3, A + A^{-1}) \quad (6)$$

$$\langle L \rangle (A) = V(A^{-4}), \quad (7)$$

where  $w(L)$  is the WRITHE of  $L$ .

see also SQUARE BRACKET POLYNOMIAL

## Bracket Product

The INNER PRODUCT in an  $L_2$  SPACE represented by an ANGLE BRACKET.

see also ANGLE BRACKET, BRA, KET,  $L_2$  SPACE, ONE-FORM

## Bracketing

Take  $x$  itself to be a bracketing, then recursively define a bracketing as a sequence  $B = (B_1, \dots, B_k)$  where  $k \geq 2$  and each  $B_i$  is a bracketing. A bracketing can be represented as a parenthesized string of  $x$ s, with parentheses removed from any single letter  $x$  for clarity of notation (Stanley 1997). Bracketings built up of binary operations only are called BINARY BRACKETINGS. For example, four letters have 11 possible bracketings:

$$\begin{array}{cccc} xxxx & (xx)xx & x(xx)x & xx(xx) \\ (xxx)x & x(xxx) & ((xx)x)x & (x(xx))x \\ (xx)(xx) & x((xx)x) & x(x(xx)), & \end{array}$$

the last five of which are binary.

The number of bracketings on  $n$  letters is given by the GENERATING FUNCTION

$$\tfrac{1}{4}(1 + x - \sqrt{1 - 6x + x^2}) = x + x^2 + 3x^3 + 11x^4 + 45x^5$$

(Schröder 1870, Stanley 1997) and the RECURRENCE RELATION

$$s_n = \frac{3(2n - 3)s_{n-1} - (n - 3)s_{n-2}}{n}$$

(Sloane), giving the sequence for  $s_n$  as 1, 1, 3, 11, 45, 197, 903, ... (Sloane's A001003). The numbers are also given by

$$s_n = \sum_{i_1 + \dots + i_k = n} s(i_1) \cdots s(i_k)$$

for  $n \geq 2$  (Stanley 1997).

The first PLUTARCH NUMBER 103,049 is equal to  $s_{10}$  (Stanley 1997), suggesting that Plutarch's problem of ten compound propositions is equivalent to the number of bracketings. In addition, Plutarch's second number 310,954 is given by  $(s_{10} + s_{11})/2 = 310,954$  (Habsieger *et al.* 1998).

### Bradley's Theorem

Let

$$S(\alpha, \beta, m; z) \equiv m \sum_{j=0}^{\infty} \frac{\Gamma(m+j(z+1))\Gamma(\beta+1+jz)}{\Gamma(m+jz+1)\Gamma(\alpha+\beta+1+j(z+1))} \frac{(\alpha+j)}{j!}$$

and  $\alpha$  be a NEGATIVE INTEGER. Then

$$S(\alpha, \beta, m; z) = \frac{\Gamma(\beta+1-m)}{\Gamma(\alpha+\beta+1-m)},$$

where  $\Gamma(z)$  is the GAMMA FUNCTION.

### Brahmagupta's Formula

For a QUADRILATERAL with sides of length  $a$ ,  $b$ ,  $c$ , and  $d$ , the AREA  $K$  is given by

$$K = \sqrt{(s-a)(s-b)(s-c)(s-d) - abcd \cos^2[\frac{1}{2}(A+B)]}, \quad (1)$$

where

$$s \equiv \frac{1}{2}(a+b+c+d) \quad (2)$$

is the SEMIPERIMETER,  $A$  is the ANGLE between  $a$  and  $d$ , and  $B$  is the ANGLE between  $b$  and  $c$ . For a CYCLIC

QUADRILATERAL (i.e., a QUADRILATERAL inscribed in a CIRCLE),  $A+B=\pi$ , so

$$K = \sqrt{(s-a)(s-b)(s-c)(s-d)} \quad (3)$$

$$= \frac{\sqrt{(bc+ad)(ac+bd)(ab+cd)}}{4R}, \quad (4)$$

where  $R$  is the RADIUS of the CIRCUMCIRCLE. If the QUADRILATERAL is INSCRIBED in one CIRCLE and CIRCUMSCRIBED on another, then the AREA FORMULA simplifies to

$$K = \sqrt{abcd}. \quad (5)$$

### Brahmagupta Identity

Let

$$\beta \equiv |B| = x^2 - ty^2,$$

where  $B$  is the BRAHMAGUPTA MATRIX, then

$$\det[B(x_1, y_1)B(x_2, y_2)] = \det[B(x_1, y_1)] \det[B(x_2, y_2)] = \beta_1 \beta_2.$$

### References

- Suryanarayan, E. R. "The Brahmagupta Polynomials." *Fib. Quart.* **34**, 30–39, 1996.

### Brahmagupta Matrix

$$B(x, y) = \begin{bmatrix} x & y \\ \pm ty & \pm x \end{bmatrix}.$$

It satisfies

$$B(x_1, y_1)B(x_2, y_2) = B(x_1x_2 \pm ty_1y_2, x_1y_2 \pm y_1x_2).$$

Powers of the matrix are defined by

$$B^n = \begin{bmatrix} x & y \\ ty & x \end{bmatrix}^n = \begin{bmatrix} x_n & y_n \\ ty_n & x_n \end{bmatrix} \equiv B_n.$$

The  $x_n$  and  $y_n$  are called BRAHMAGUPTA POLYNOMIALS. The Brahmagupta matrices can be extended to NEGATIVE INTEGERS

$$B^{-n} = \begin{bmatrix} x & y \\ ty & x \end{bmatrix}^{-n} = \begin{bmatrix} x_{-n} & y_{-n} \\ ty_{-n} & x_{-n} \end{bmatrix} \equiv B_{-n}.$$

see also BRAHMAGUPTA IDENTITY

### References

- Suryanarayan, E. R. "The Brahmagupta Polynomials." *Fib. Quart.* **34**, 30–39, 1996.

### Brahmagupta Polynomial

One of the POLYNOMIALS obtained by taking POWERS of the BRAHMAGUPTA MATRIX. They satisfy the recurrence relation

$$x_{n+1} = xx_n + ty_n \quad (1)$$

$$y_{n+1} = xy_n + yx_n. \quad (2)$$

A list of many others is given by Suryanarayan (1996). Explicitly,

$$x_n = x^n + t \binom{n}{2} x^{n-2} y^2 + t^2 \binom{n}{4} x^{n-4} y^4 + \dots \quad (3)$$

$$y_n = nx^{n-1}y + t \binom{n}{3} x^{n-3} y^3 + t^2 \binom{n}{5} x^{n-5} y^5 + \dots \quad (4)$$

The Brahmagupta POLYNOMIALS satisfy

$$\frac{\partial x_n}{\partial x} = \frac{\partial y_n}{\partial y} = nx_{n-1} \quad (5)$$

$$\frac{\partial x_n}{\partial y} = t \frac{\partial y_n}{\partial y} = nty_{n-1}. \quad (6)$$

The first few POLYNOMIALS are

$$\begin{aligned} x_0 &= 0 \\ x_1 &= x \\ x_2 &= x^2 + ty^2 \\ x_3 &= x^3 + 3txy^2 \\ x_4 &= x^4 + 6tx^2y^2 + t^2y^4 \end{aligned}$$

and

$$\begin{aligned} y_0 &= 0 \\ y_1 &= y \\ y_2 &= 2xy \\ y_3 &= 3x^2y + ty^3 \\ y_4 &= 4x^3y + 4txy^3. \end{aligned}$$

Taking  $x = y = 1$  and  $t = 2$  gives  $y_n$  equal to the PELL NUMBERS and  $x_n$  equal to half the Pell-Lucas numbers. The Brahmagupta POLYNOMIALS are related to the MORGAN-VOYCE POLYNOMIALS, but the relationship given by Suryanarayan (1996) is incorrect.

### Brahmagupta's Problem

Solve the PELL EQUATION

$$x^2 - 92y^2 = 1$$

in INTEGERS. The smallest solution is  $x = 1151$ ,  $y = 120$ .

see also DIOPHANTINE EQUATION, PELL EQUATION

### Braid

An intertwining of strings attached to top and bottom "bars" such that each string never "turns back up." In other words, the path of a braid in something that a falling object could trace out if acted upon only by gravity and horizontal forces.

see also BRAID GROUP

#### References

Christy, J. "Braids." <http://www.mathsource.com/cgi-bin/MathSource/Applications/Mathematics/0202-228>.

### Braid Group

Also called ARTIN BRAID GROUPS. Consider  $n$  strings, each oriented vertically from a lower to an upper "bar." If this is the least number of strings needed to make a closed braid representation of a LINK,  $n$  is called the BRAID INDEX. Now enumerate the possible braids in a group, denoted  $B_n$ . A general  $n$ -braid is constructed by iteratively applying the  $\sigma_i$  ( $i = 1, \dots, n-1$ ) operator, which switches the lower endpoints of the  $i$ th and  $(i+1)$ th strings—keeping the upper endpoints fixed—with the  $(i+1)$ th string brought *above* the  $i$ th string. If the  $(i+1)$ th string passes *below* the  $i$ th string, it is denoted  $\sigma_i^{-1}$ .

Topological equivalence for different representations of a BRAID WORD  $\prod_i \sigma_i$  and  $\prod_i \sigma'_i$  is guaranteed by the conditions

$$\begin{cases} \sigma_i \sigma_j = \sigma'_j \sigma'_i & \text{for } |i-j| \geq 2 \\ \sigma_i \sigma_{i+1} \sigma_i = \sigma'_{i+1} \sigma'_i \sigma'_{i+1} & \text{for all } i \end{cases}$$

as first proved by E. Artin. Any  $n$ -braid is expressed as a BRAID WORD, e.g.,  $\sigma_1 \sigma_2 \sigma_3 \sigma_2^{-1} \sigma_1$  is a BRAID WORD for the braid group  $B_3$ . When the opposite ends of the braids are connected by nonintersecting lines, KNOTS are formed which are identified by their braid group and BRAID WORD. The BURAU REPRESENTATION gives a matrix representation of the braid groups.

**Braid Index**

The least number of strings needed to make a closed braid representation of a LINK. The braid index is equal to the least number of SEIFERT CIRCLES in any projection of a KNOT (Yamada 1987). Also, for a nonsplittable LINK with CROSSING NUMBER  $c(L)$  and braid index  $i(L)$ ,

$$c(L) \geq 2[i(L) - 1]$$

(Ohyama 1993). Let  $E$  be the largest and  $e$  the smallest POWER of  $\ell$  in the HOMFLY POLYNOMIAL of an oriented LINK, and  $i$  be the braid index. Then the MORTON-FRANKS-WILLIAMS INEQUALITY holds,

$$i \geq \frac{1}{2}(E - e) + 1$$

(Franks and Williams 1987). The inequality is sharp for all PRIME KNOTS up to 10 crossings with the exceptions of 09<sub>042</sub>, 09<sub>049</sub>, 10<sub>132</sub>, 10<sub>150</sub>, and 10<sub>156</sub>.

**Braid Word**

Any  $n$ -braid is expressed as a braid word, e.g.,  $\sigma_1 \sigma_2 \sigma_3 \sigma_2^{-1} \sigma_1$  is a braid word for the BRAID GROUP  $B_3$ . By ALEXANDER'S THEOREM, any LINK is representable by a closed braid, but there is no general procedure for reducing a braid word to its simplest form. However, MARKOV'S THEOREM gives a procedure for identifying different braid words which represent the same LINK.

Let  $b_+$  be the sum of POSITIVE exponents, and  $b_-$  the sum of NEGATIVE exponents in the BRAID GROUP  $B_n$ . If

$$b_+ - 3b_- - n + 1 > 0,$$

then the closed braid  $b$  is not AMPHICHIRAL (Jones 1985).

**Braikenridge-Maclaurin Construction**

The converse of PASCAL'S THEOREM. Let  $A_1, B_2, C_1, A_2$ , and  $B_1$  be the five points on a CONIC. Then the CONIC is the LOCUS of the point

$$C_2 = A_1(z \cdot C_1 A_2) \cdot B_1(z \cdot C_1 B_2),$$

where  $z$  is a line through the point  $A_1 B_2 \cdot B_1 A_2$ .

see also PASCAL'S THEOREM

**Branch**

The segments of a TREE between the points of connection (FORKS).

see also FORK, LEAF (TREE)

**Branch Cut**

A line in the COMPLEX PLANE across which a FUNCTION is discontinuous.

function	branch cut(s)
$\cos^{-1} z$	$(-\infty, -1)$ and $(1, \infty)$
$\cosh^{-1}$	$(-\infty, 1)$
$\cot^{-1} z$	$(-i, i)$
$\coth^{-1}$	$[-1, 1]$
$\csc^{-1} z$	$(-1, 1)$
$\operatorname{csch}^{-1}$	$(-i, i)$
$\ln z$	$(-\infty, 0]$
$\sec^{-1} z$	$(-1, 1)$
$\operatorname{sech}^{-1}$	$(\infty, 0]$ and $(1, \infty)$
$\sin^{-1} z$	$(-\infty, -1)$ and $(1, \infty)$
$\sinh^{-1}$	$(-i\infty, -i)$ and $(i, i\infty)$
$\sqrt{z}$	$(-\infty, 0)$
$\tan^{-1} z$	$(-i\infty, -i)$ and $(i, i\infty)$
$\tanh^{-1}$	$(-\infty, -1]$ and $[1, \infty)$
$z^n, n \notin \mathbb{Z}$	$(-\infty, 0)$ for $\Re[n] \leq 0$ ; $(-\infty, 0]$ for $\Re[n] > 0$

**Branch Line**

see BRANCH CUT

**Branch Point**

An argument at which identical points in the COMPLEX PLANE are mapped to different points. For example, consider

$$f(z) = z^a.$$

Then  $f(e^{0i}) = f(1) = 1$ , but  $f(e^{2\pi i}) = e^{2\pi ia}$ , despite the fact that  $e^{i0} = e^{2\pi i}$ . PINCH POINTS are also called branch points.

### Braun's Conjecture

Let  $B = \{b_1, b_2, \dots\}$  be an INFINITE Abelian SEMI-GROUP with linear order  $b_1 < b_2 < \dots$  such that  $b_1$  is the unit element and  $a < b$  IMPLIES  $ac < bc$  for  $a, b, c \in B$ . Define a MÖBIUS FUNCTION  $\mu$  on  $B$  by  $\mu(b_1) = 1$  and

$$\sum_{b_d | b_n} \mu(b_d) = 0$$

for  $n = 2, 3, \dots$ . Further suppose that  $\mu(b_n) = \mu(n)$  (the true MÖBIUS FUNCTION) for all  $n \geq 1$ . Then Braun's conjecture states that

$$b_{mn} = b_m b_n$$

for all  $m, n \geq 1$ .

see also MÖBIUS PROBLEM

#### References

### Breeder

A pair of POSITIVE INTEGERS  $(a_1, a_2)$  such that the equations

$$a_1 + a_2 x = \sigma(a_1) = \sigma(a_2)(x + 1)$$

have a POSITIVE INTEGER solution  $x$ , where  $\sigma(n)$  is the DIVISOR FUNCTION. If  $x$  is PRIME, then  $(a_1, a_2 x)$  is an AMICABLE PAIR (te Riele 1986).  $(a_1, a_2)$  is a "special" breeder if

$$\begin{aligned} a_1 &= au \\ a_2 &= a, \end{aligned}$$

where  $a$  and  $u$  are RELATIVELY PRIME,  $(a, u) = 1$ . If regular amicable pairs of type  $(i, 1)$  with  $i \geq 2$  are of the form  $(au, ap)$  with  $p$  PRIME, then  $(au, a)$  are special breeders (te Riele 1986).

#### References

**Brelaz's Heuristic Algorithm**

An ALGORITHM which can be used to find a good, but not necessarily minimal, EDGE or VERTEX coloring for a GRAPH.

see also CHROMATIC NUMBER

**Brent's Factorization Method**

A modification of the POLLARD  $\rho$  FACTORIZATION METHOD which uses

$$x_{i+1} = x_i^2 - c \pmod{n}.$$

**References**

Brent, R. "An Improved Monte Carlo Factorization Algorithm." *Nordisk Tidsskrift for Informationsbehandling (BIT)* **20**, 176–184, 1980.

**Brent's Method**

A ROOT-finding ALGORITHM which combines root bracketing, bisection, and INVERSE QUADRATIC INTERPOLATION. It is sometimes known as the VAN WIJNGAARDEN-DEKER-BRENT METHOD.

Brent's method uses a LAGRANGE INTERPOLATING POLYNOMIAL of degree 2. Brent (1973) claims that this method will always converge as long as the values of the function are computable within a given region containing a ROOT. Given three points  $x_1$ ,  $x_2$ , and  $x_3$ , Brent's method fits  $x$  as a quadratic function of  $y$ , then uses the interpolation formula

$$x = \frac{[y - f(x_1)][y - f(x_2)]x_3}{[f(x_3) - f(x_1)][f(x_3) - f(x_2)]} + \frac{[y - f(x_2)][y - f(x_3)]x_1}{[f(x_1) - f(x_2)][f(x_1) - f(x_3)]} + \frac{[y - f(x_3)][y - f(x_1)]x_2}{[f(x_2) - f(x_3)][f(x_2) - f(x_1)]}. \quad (1)$$

Subsequent root estimates are obtained by setting  $y = 0$ , giving

$$x = b + \frac{P}{Q}, \quad (2)$$

where

$$P = S[R(R - T)(x_3 - x_2) - (1 - R)(x_2 - x_1)] \quad (3)$$

$$Q = (T - 1)(R - 1)(S - 1) \quad (4)$$

with

$$R \equiv \frac{f(x_2)}{f(x_3)} \quad (5)$$

$$S \equiv \frac{f(x_2)}{f(x_1)} \quad (6)$$

$$T \equiv \frac{f(x_1)}{f(x_3)} \quad (7)$$

(Press et al. 1992).

**Brent-Salamin Formula**

A formula which uses the ARITHMETIC-GEOMETRIC MEAN to compute  $\pi$ . It has quadratic convergence and is also called the GAUSS-SALAMIN FORMULA and SALAMIN FORMULA. Let

$$a_{n+1} = \frac{1}{2}(a_n + b_n) \quad (1)$$

$$b_{n+1} = \sqrt{a_n b_n} \quad (2)$$

$$c_{n+1} = \frac{1}{2}(a_n - b_n) \quad (3)$$

$$d_n \equiv a_n^2 - b_n^2, \quad (4)$$

and define the initial conditions to be  $a_0 = 1$ ,  $b_0 = 1/\sqrt{2}$ . Then iterating  $a_n$  and  $b_n$  gives the ARITHMETIC-GEOMETRIC MEAN, and  $\pi$  is given by

$$\pi = \frac{4[M(1, 2^{-1/2})]^2}{1 - \sum_{j=1}^{\infty} 2^{j+1} d_j} \quad (5)$$

$$= \frac{4[M(1, 2^{-1/2})]^2}{1 - \sum_{j=1}^{\infty} 2^{j+1} c_j^2}. \quad (6)$$

King (1924) showed that this formula and the LEGENDRE RELATION are equivalent and that either may be derived from the other.

see also ARITHMETIC-GEOMETRIC MEAN,  $\pi$

# Brianchon Point

The point of CONCURRENCE of the joins of the VERTICES of a TRIANGLE and the points of contact of a CONIC SECTION INSCRIBED in the TRIANGLE. A CONIC INSCRIBED in a TRIANGLE has an equation of the form

$$\frac{f}{u} + \frac{g}{v} + \frac{h}{w} = 0,$$

so its Brianchon point has TRILINEAR COORDINATES  $(1/f, 1/g, 1/h)$ . For KIEPERT'S PARABOLA, the Brianchon point has TRIANGLE CENTER FUNCTION

$$\alpha = \frac{1}{a(b^2 - c^2)},$$

which is the STEINER POINT.

# Brianchon's Theorem

The DUAL of PASCAL'S THEOREM. It states that, given a 6-sided POLYGON CIRCUMSCRIBED on a CONIC SECTION, the lines joining opposite VERTICES (DIAGONALS) meet in a single point.

# Bridge Card Game

Bridge is a CARD game played with a normal deck of 52 cards. The number of possible distinct 13-card hands is

$$N = \binom{52}{13} = 635,013,559,600.$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. While the chances of being dealt a hand of 13 CARDS (out of 52) of the same suit are

$$\frac{4}{\binom{52}{13}} = \frac{1}{158,753,389,900},$$

the chance that one of four players will receive a hand of a single suit is

$$\frac{1}{39,688,347,497}.$$

There are special names for specific types of hands. A ten, jack, queen, king, or ace is called an "honor." Getting the ten, jack, queen, king, and ace of three suits and the ace, king, and queen, and jack of the remaining suit is called 13 top honors. Getting all cards of the same suit is called a 13-card suit. Getting 12 cards of same suit with ace high and the 13th card *not* an ace is called 2-card suit, ace high. Getting *no* honors is called a Yarborough.

The probabilities of being dealt 13-card bridge hands of a given type are given below. As usual, for a hand with probability  $P$ , the ODDS against being dealt it are  $(1/P) - 1 : 1$ .

Hand	Exact	Probability
13 top honors	$\frac{4}{N}$	$\frac{1}{158,753,389,900}$
13-card suit	$\frac{4}{N}$	$\frac{1}{158,753,389,900}$
12-card suit, ace high	$\frac{4 \cdot 12 \cdot 36}{N}$	$\frac{4}{1,469,938,795}$
Yarborough	$\frac{\binom{32}{13}}{N}$	$\frac{5,394}{9,860,459}$
four aces	$\frac{\binom{48}{9}}{N}$	$\frac{11}{4,165}$
nine honors	$\frac{\binom{20}{9} \binom{32}{4}}{N}$	$\frac{888,212}{93,384,347}$

Hand	Probability	Odds
13 top honors	$6.30 \times 10^{-12}$	158,753,389,899:1
13-card suit	$6.30 \times 10^{-12}$	158,753,389,899:1
12-card suit, ace high	$2.72 \times 10^{-9}$	367,484,697.8:1
Yarborough	$5.47 \times 10^{-4}$	1,827.0:1
four aces	$2.64 \times 10^{-3}$	377.6:1
nine honors	$9.51 \times 10^{-3}$	104.1:1

**Bridge of Königsberg**

see KÖNIGSBERG BRIDGE PROBLEM

**Bridge Knot**

An  $n$ -bridge knot is a knot with BRIDGE NUMBER  $n$ . The set of 2-bridge knots is identical to the set of rational knots. If  $L$  is a 2-BRIDGE KNOT, then the BLM/HO POLYNOMIAL  $Q$  and JONES POLYNOMIAL  $V$  satisfy

$$Q_L(z) = 2z^{-1}V_L(t)V_L(t^{-1} + 1 - 2z^{-1}),$$

where  $z \equiv -t - t^{-1}$  (Kanenobu and Sumi 1993). Kanenobu and Sumi also give a table containing the number of distinct 2-bridge knots of  $n$  crossings for  $n = 10$  to 22, both not counting and counting MIRROR IMAGES as distinct.

 Schubert, H. "Knotten mit zwei Brücken." *Math. Z.* **65**, 133–170, 1956.

**Bridge Number**

The least number of unknotted arcs lying above the plane in any projection. The knot 05<sub>05</sub> has bridge number 2. Such knots are called 2-BRIDGE KNOTS. There is a one-to-one correspondence between 2-BRIDGE KNOTS and rational knots. The knot 08<sub>010</sub> is a 3-bridge knot. A knot with bridge number  $b$  is an  $n$ -EMBEDDABLE KNOT where  $n \leq b$ .

**Bring-Jerrard Quintic Form**

A TSCHIRNHAUSEN TRANSFORMATION can be used to algebraically transform a general QUINTIC EQUATION to the form

$$z^5 + c_1z + c_0 = 0. \quad (1)$$

In practice, the general quintic is first reduced to the PRINCIPAL QUINTIC FORM

$$y^5 + b_2y^2 + b_1y + b_0 = 0 \quad (2)$$

before the transformation is done. Then, we require that the sum of the third POWERS of the ROOTS vanishes, so  $s_3(y_j) = 0$ . We assume that the ROOTS  $z_i$  of the Bring-Jerrard quintic are related to the ROOTS  $y_i$  of the PRINCIPAL QUINTIC FORM by

$$z_i = \alpha y_i^4 + \beta y_i^3 + \gamma y_i^2 + \delta y_i + \epsilon. \quad (3)$$

In a similar manner to the PRINCIPAL QUINTIC FORM transformation, we can express the COEFFICIENTS  $c_j$  in terms of the  $b_j$ .

see also BRING QUINTIC FORM, PRINCIPAL QUINTIC FORM, QUINTIC EQUATION

**Bring Quintic Form**

A TSCHIRNHAUSEN TRANSFORMATION can be used to take a general QUINTIC EQUATION to the form

$$x^5 - x - a = 0,$$

where  $a$  may be COMPLEX.

# Brioschi Formula

For a curve with METRIC

$$ds^2 = E du^2 + F du dv + G dv^2, \quad (1)$$

where  $E$ ,  $F$ , and  $G$  is the first FUNDAMENTAL FORM, the GAUSSIAN CURVATURE is

$$K = \frac{M_1 + M_2}{(EG - F^2)^2}, \quad (2)$$

where

$$M_1 \equiv \begin{vmatrix} -\frac{1}{2}E_{uv} + F_{uv} - \frac{1}{2}G_{uu} & \frac{1}{2}E_u & F_u - \frac{1}{2}E_v \\ F_v - \frac{1}{2}G_u & E & F \\ \frac{1}{2}G_v & F & G \end{vmatrix} \quad (3)$$

$$M_2 \equiv \begin{vmatrix} 0 & \frac{1}{2}E_v & \frac{1}{2}G_u \\ \frac{1}{2}E_v & E & F \\ \frac{1}{2}G_u & F & G \end{vmatrix}, \quad (4)$$

which can also be written

$$K = -\frac{1}{\sqrt{EG}} \left[ \frac{\partial}{\partial u} \left( \frac{1}{\sqrt{E}} \frac{\partial \sqrt{G}}{\partial u} \right) + \frac{\partial}{\partial v} \left( \frac{1}{\sqrt{G}} \frac{\partial \sqrt{E}}{\partial v} \right) \right] \quad (5)$$

$$= -\frac{1}{2\sqrt{EG}} \left[ \frac{\partial}{\partial u} \left( \frac{G_u}{\sqrt{EG}} \right) + \frac{\partial}{\partial v} \left( \frac{E_v}{\sqrt{EG}} \right) \right]. \quad (6)$$

# Brocard Angle

Define the first BROCARD POINT as the interior point  $\Omega$  of a TRIANGLE for which the ANGLES  $\angle\Omega AB$ ,  $\angle\Omega BC$ , and  $\angle\Omega CA$  are equal. Similarly, define the second BROCARD POINT as the interior point  $\Omega'$  for which the ANGLES  $\angle\Omega' AC$ ,  $\angle\Omega' CB$ , and  $\angle\Omega' BA$  are equal. Then the ANGLES in both cases are equal, and this angle is called the Brocard angle, denoted  $\omega$ .

The Brocard angle  $\omega$  of a TRIANGLE  $\triangle ABC$  is given by the formulas

$$\cot \omega = \cot A + \cot B + \cot C \quad (1)$$

$$= \left( \frac{a^2 + b^2 + c^2}{4\Delta} \right) \quad (2)$$

$$= \frac{1 + \cos \alpha_1 \cos \alpha_2 \cos \alpha_3}{\sin \alpha_1 \sin \alpha_2 \sin \alpha_3} \quad (3)$$

$$= \frac{\sin^2 \alpha_1 + \sin^2 \alpha_2 + \sin^2 \alpha_3}{2 \sin \alpha_1 \sin \alpha_2 \sin \alpha_3} \quad (4)$$

$$= \frac{a_1 \sin \alpha_1 + a_2 \sin \alpha_2 + a_3 \sin \alpha_3}{a_1 \cos \alpha_1 + a_2 \cos \alpha_2 + a_3 \cos \alpha_3} \quad (5)$$

$$\csc^2 \omega = \csc^2 \alpha_1 + \csc^2 \alpha_2 + \csc^2 \alpha_3 \quad (6)$$

$$\sin \omega = \frac{2\Delta}{\sqrt{a_1^2 a_2^2 + a_2^2 a_3^2 + a_3^2 a_1^2}}, \quad (7)$$

where  $\Delta$  is the TRIANGLE AREA,  $A$ ,  $B$ , and  $C$  are ANGLES, and  $a$ ,  $b$ , and  $c$  are side lengths.

If an ANGLE  $\alpha$  of a TRIANGLE is given, the maximum possible Brocard angle is given by

$$\cot \omega = \frac{3}{2} \tan(\frac{1}{2}\alpha) + \frac{1}{2} \cos(\frac{1}{2}\alpha). \quad (8)$$

Let a TRIANGLE have ANGLES  $A$ ,  $B$ , and  $C$ . Then

$$\sin A \sin B \sin C \leq k ABC, \quad (9)$$

where

$$k = \left( \frac{3\sqrt{3}}{2\pi} \right)^3 \quad (10)$$

(Le Lionnais 1983). This can be used to prove that

$$8\omega^3 < ABC \quad (11)$$

(Abi-Khuzam 1974).

 Le Lionnais, F. *Les nombres remarquables*. Paris: Hermann, p. 28, 1983.

#### Brocard Axis

The LINE  $KO$  passing through the LEMOINE POINT  $K$  and CIRCUMCENTER  $O$  of a TRIANGLE. The distance  $\overline{OK}$  is called the BROCARD DIAMETER. The Brocard axis is PERPENDICULAR to the LEMOINE AXIS and is the ISOGONAL CONJUGATE of KIEPERT'S HYPERBOLA. It has equations

$$\sin(B - C)\alpha + \sin(C - A)\beta + \sin(A - B)\gamma = 0$$

$$bc(b^2 - c^2)\alpha + ca(c^2 - a^2)\beta + ab(a^2 - b^2)\gamma = 0.$$

The LEMOINE POINT, CIRCUMCENTER, ISODYNAMIC POINTS, and BROCARD MIDPOINT all lie along the Brocard axis. Note that the Brocard axis is *not* equivalent to the BROCARD LINE.

see also BROCARD CIRCLE, BROCARD DIAMETER, BROCARD LINE

#### Brocard Circle

The CIRCLE passing through the first and second BROCARD POINTS  $\Omega$  and  $\Omega'$ , the LEMOINE POINT  $K$ , and the CIRCUMCENTER  $O$  of a given TRIANGLE. The BROCARD POINTS  $\Omega$  and  $\Omega'$  are symmetrical about the LINE  $\overleftrightarrow{KO}$ , which is called the BROCARD LINE. The LINE SEGMENT  $\overline{KO}$  is called the BROCARD DIAMETER, and it has length

$$\overline{OK} = \frac{\overline{O\Omega}}{\cos \omega} = \frac{R\sqrt{1 - 4\sin^2 \omega}}{\cos \omega},$$

where  $R$  is the CIRCUMRADIUS and  $\omega$  is the BROCARD ANGLE. The distance between either of the BROCARD POINTS and the LEMOINE POINT is

$$\overline{\Omega K} = \overline{\Omega' K} = \overline{\Omega O} \tan \omega.$$

see also BROCARD ANGLE, BROCARD DIAMETER, BROCARD POINTS

#### References

- Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, p. 272, 1929.

#### Brocard's Conjecture

$$\pi(p_{n+1}^2) - \pi(p_n^2) \geq 4$$

for  $n \geq 2$  where  $\pi$  is the PRIME COUNTING FUNCTION.

see also ANDRICA'S CONJECTURE

#### Brocard Diameter

The LINE SEGMENT  $\overline{KO}$  joining the LEMOINE POINT  $K$  and CIRCUMCENTER  $O$  of a given TRIANGLE. It is the DIAMETER of the TRIANGLE'S BROCARD CIRCLE, and lies along the BROCARD AXIS. The Brocard diameter has length

$$\overline{OK} = \frac{\overline{O\Omega}}{\cos \omega} = \frac{R\sqrt{1 - 4\sin^2 \omega}}{\cos \omega},$$

where  $\Omega$  is the first BROCARD POINT,  $R$  is the CIRCUMRADIUS, and  $\omega$  is the BROCARD ANGLE.

see also BROCARD AXIS, BROCARD CIRCLE, BROCARD LINE, BROCARD POINTS

#### Brocard Line

A LINE from any of the VERTICES  $A_i$  of a TRIANGLE to the first  $\Omega$  or second  $\Omega'$  BROCARD POINT. Let the ANGLE at a VERTEX  $A_i$  also be denoted  $A_i$ , and denote the intersections of  $A_1\Omega$  and  $A_1\Omega'$  with  $A_2A_3$  as  $W_1$  and  $W_2$ . Then the ANGLES involving these points are

$$\angle A_1\Omega W_3 = A_1 \quad (1)$$

$$\angle W_3\Omega A_2 = A_3 \quad (2)$$

$$\angle A_2\Omega W_1 = A_2. \quad (3)$$

Distances involving the points  $W_i$  and  $W'_i$  are given by

$$\overline{A_2\Omega} = \frac{a_3}{\sin A_2} \sin \omega \quad (4)$$

$$\frac{\overline{A_2\Omega}}{\overline{A_3\Omega}} = \frac{a_3^2}{a_1a_2} = \frac{\sin(A_3 - \omega)}{\sin \omega} \quad (5)$$

$$\frac{\overline{W_3A_1}}{\overline{W_3A_2}} = \frac{a_2 \sin \omega}{a_1 \sin(A_3 - \omega)} = \left(\frac{a_2}{a_3}\right)^2, \quad (6)$$

where  $\omega$  is the BROCARD ANGLE (Johnson 1929, pp. 267–268).

The Brocard line, MEDIAN  $M$ , and LEMOINE POINT  $K$  are concurrent, with  $A_1\Omega_1$ ,  $A_2K$ , and  $A_3M$  meeting at a point  $P$ . Similarly,  $A_1\Omega'$ ,  $A_2M$ , and  $A_3K$  meet at a point which is the ISOGONAL CONJUGATE point of  $P$  (Johnson 1929, pp. 268–269).

see also BROCARD AXIS, BROCARD DIAMETER, BROCARD POINTS, ISOGONAL CONJUGATE, LEMOINE POINT, MEDIAN (TRIANGLE)

#### References

Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, pp. 263–286, 1929.

### Brocard Midpoint

The MIDPOINT of the BROCARD POINTS. It has TRIANGLE CENTER FUNCTION

$$\alpha = a(b^2 + c^2) = \sin(A + \omega),$$

where  $\omega$  is the BROCARD ANGLE. It lies on the BROCARD AXIS.

#### References

Kimberling, C. “Central Points and Central Lines in the Plane of a Triangle.” *Math. Mag.* **67**, 163–187, 1994.

### Brocard Points

The first Brocard point is the interior point  $\Omega$  (or  $\tau_1$  or  $Z_1$ ) of a TRIANGLE for which the ANGLES  $\angle\Omega AB$ ,  $\angle\Omega BC$ , and  $\angle\Omega CA$  are equal. The second Brocard point is the interior point  $\Omega'$  (or  $\tau_2$  or  $Z_2$ ) for which the ANGLES  $\angle\Omega' AC$ ,  $\angle\Omega' CB$ , and  $\angle\Omega' BA$  are equal. The ANGLES in both cases are equal to the BROCARD ANGLE  $\omega$ ,

$$\begin{aligned} \omega &= \angle\Omega AB = \angle\Omega BC = \angle\Omega CA \\ &= \angle\Omega' AC = \angle\Omega' CB = \angle\Omega' BA. \end{aligned}$$

The first two Brocard points are ISOGONAL CONJUGATES (Johnson 1929, p. 266).

Let  $C_{BC}$  be the CIRCLE which passes through the vertices  $B$  and  $C$  and is TANGENT to the line  $AC$  at  $C$ , and similarly for  $C_{AB}$  and  $C_{AC}$ . Then the CIRCLES  $C_{AB}$ ,  $C_{BC}$ , and  $C_{AC}$  intersect in the first Brocard point  $\Omega$ . Similarly, let  $C'_{BC}$  be the CIRCLE which passes through the vertices  $B$  and  $C$  and is TANGENT to the line  $AB$  at  $B$ , and similarly for  $C'_{AB}$  and  $C'_{AC}$ . Then the CIRCLES  $C'_{AB}$ ,  $C'_{BC}$ , and  $C'_{AC}$  intersect in the second Brocard points  $\Omega'$  (Johnson 1929, pp. 264–265).

The PEDAL TRIANGLES of  $\Omega$  and  $\Omega'$  are congruent, and SIMILAR to the TRIANGLE  $\triangle ABC$  (Johnson 1929, p. 269). Lengths involving the Brocard points include

$$\overline{O\Omega} = \overline{O\Omega'} = R\sqrt{1 - 4\sin^2 \omega} \quad (1)$$

$$\overline{\Omega\Omega'} = 2R\sin \omega\sqrt{1 - 4\sin^2 \omega}. \quad (2)$$

Brocard's third point is related to a given TRIANGLE by the TRIANGLE CENTER FUNCTION

$$\alpha = a^{-3} \quad (3)$$

(Casey 1893, Kimberling 1994). The third Brocard point  $\Omega''$  (or  $\tau_3$  or  $Z_3$ ) is COLLINEAR with the SPIEKER CENTER and the ISOTOMIC CONJUGATE POINT of its TRIANGLE'S INCENTER.

**Brocard Triangles**

Let the point of intersection of  $A_2\Omega$  and  $A_3\Omega'$  be  $B_1$ , where  $\Omega$  and  $\Omega'$  are the BROCARD POINTS, and similarly define  $B_2$  and  $B_3$ .  $B_1B_2B_3$  is the first Brocard triangle, and is inversely similar to  $A_1A_2A_3$ . It is inscribed in the BROCARD CIRCLE drawn with  $OK$  as the DIAMETER. The triangles  $B_1A_2A_3$ ,  $B_2A_3A_1$ , and  $B_3A_1A_2$  are ISOSCELES TRIANGLES with base angles  $\omega$ , where  $\omega$  is the BROCARD ANGLE. The sum of the areas of the ISOSCELES TRIANGLES is  $\Delta$ , the AREA of TRIANGLE  $A_1A_2A_3$ . The first Brocard triangle is in perspective with the given TRIANGLE, with  $A_1B_1$ ,  $A_2B_2$ , and  $A_3B_3$  CONCURRENT. The MEDIAN POINT of the first Brocard triangle is the MEDIAN POINT  $M$  of the original triangle. The Brocard triangles are in perspective at  $M$ .

Let  $c_1$ ,  $c_2$ , and  $c_3$  and  $c'_1$ ,  $c'_2$ , and  $c'_3$  be the CIRCLES intersecting in the BROCARD POINTS  $\Omega$  and  $\Omega'$ , respectively. Let the two circles  $c_1$  and  $c'_1$  tangent at  $A_1$  to  $A_1A_2$  and  $A_1A_3$ , and passing respectively through  $A_3$  and  $A_2$ , meet again at  $C_1$ . The triangle  $C_1C_2C_3$  is the second Brocard triangle. Each VERTEX of the second Brocard triangle lies on the second BROCARD CIRCLE.

The two Brocard triangles are in perspective at  $M$ .

Honsberger, R. *Mathematical Gems I*. Washington, DC: Math. Assoc. Amer., pp. 121–125, 1973.

**Brown's Criterion**

A SEQUENCE  $\{\nu_i\}$  of nondecreasing POSITIVE INTEGERS is COMPLETE IFF

1.  $\nu_1 = 1$ .
2. For all  $k = 2, 3, \dots$ ,

$$s_{k-1} = \nu_1 + \nu_2 + \dots + \nu_{k-1} \geq \nu_k - 1.$$

A corollary states that a SEQUENCE for which  $\nu_1 = 1$  and  $\nu_{k+1} \leq 2\nu_k$  is COMPLETE (Honsberger 1985).

see also COMPLETE SEQUENCE

**Brown Function**

For a FRACTAL PROCESS with values  $y(t - \Delta t)$  and  $y(t + \Delta t)$ , the correlation between these two values is given by the Brown function

$$r = 2^{2H-1} - 1,$$

also known as the BACHELIER FUNCTION, LÉVY FUNCTION, or WIENER FUNCTION.

**Brown Numbers**

Brown numbers are PAIRS  $(m, n)$  of INTEGERS satisfying the condition of BROCARD'S PROBLEM, i.e., such that

$$n! + 1 = m^2$$

where  $n!$  is the FACTORIAL and  $m^2$  is a SQUARE NUMBER. Only three such PAIRS of numbers are known: (5,4), (11,5), (71,7), and Erdős conjectured that these are the only three such PAIRS. Le Lionnais (1983) points out that there are 3 numbers less than 200,000 for which

$$(n-1)! + 1 \equiv 0 \pmod{n^2},$$

namely 5, 13, and 563.

**Bruck-Ryser-Chowla Theorem**

If  $n \equiv 1, 2 \pmod{4}$ , and the SQUAREFREE part of  $n$  is divisible by a PRIME  $p \equiv 3 \pmod{4}$ , then no DIFFERENCE SET of ORDER  $n$  exists. Equivalently, if a PROJECTIVE PLANE of order  $n$  exists, and  $n \equiv 1$  or  $2 \pmod{4}$ , then  $n$  is the sum of two SQUARES.

Dinitz and Stinson (1992) give the theorem in the following form. If a symmetric  $(v, k, \lambda)$ -BLOCK DESIGN exists, then

1. If  $v$  is EVEN, then  $k - \lambda$  is a SQUARE NUMBER,
2. If  $v$  is ODD, the the DIOPHANTINE EQUATION

$$x^2 = (k - \lambda)y^2 + (-1)^{(v-1)/2} \lambda z^2$$

has a solution in integers, not all of which are 0.

**Bruck-Ryser Theorem**

see BRUCK-RYSER-CHOWLA THEOREM

**Brun's Constant**

The number obtained by adding the reciprocals of the TWIN PRIMES,

$$B \equiv \left(\frac{1}{3} + \frac{1}{5}\right) + \left(\frac{1}{5} + \frac{1}{7}\right) + \left(\frac{1}{11} + \frac{1}{13}\right) + \left(\frac{1}{17} + \frac{1}{19}\right) + \dots, \quad (1)$$

By BRUN'S THEOREM, the constant converges to a definite number as  $p \rightarrow \infty$ . Any finite sum underestimates  $B$ . Shanks and Wrench (1974) used all the TWIN PRIMES among the first 2 million numbers. Brent (1976) calculated all TWIN PRIMES up to 100 billion and obtained (Ribenoim 1989, p. 146)

$$B \approx 1.90216054, \quad (2)$$

assuming the truth of the first HARDY-LITTLEWOOD CONJECTURE. Using TWIN PRIMES up to  $10^{14}$ , Nicely (1996) obtained

$$B \approx 1.9021605778 \pm 2.1 \times 10^{-9} \quad (3)$$

(Cipra 1995, 1996), in the process discovering a bug in Intel's® Pentium™ microprocessor. The value given by Le Lionnais (1983) is incorrect.

**Bubble**

A bubble is a MINIMAL SURFACE of the type that is formed by soap film. The simplest bubble is a single SPHERE. More complicated forms occur when multiple bubbles are joined together. Two outstanding problems involving bubbles are to find the arrangements with the smallest PERIMETER (planar problem) or SURFACE AREA (AREA problem) which enclose and separate  $n$  given unit areas or volumes in the plane or in space. For  $n = 2$ , the problems are called the DOUBLE BUBBLE CONJECTURE and the solution to both problems is known to be the DOUBLE BUBBLE.

**Buffon-Laplace Needle Problem**

Find the probability  $P(\ell, a, b)$  that a needle of length  $\ell$  will land on a line, given a floor with a grid of equally spaced PARALLEL LINES distances  $a$  and  $b$  apart, with  $\ell > a, b$ .

$$P(\ell, a, b) = \frac{2\ell(a+b) - \ell^2}{\pi ab}.$$

see also BUFFON'S NEEDLE PROBLEM

**Buffon's Needle Problem**

Find the probability  $P(\ell, d)$  that a needle of length  $\ell$  will land on a line, given a floor with equally spaced PARALLEL LINES a distance  $d$  apart.

$$P(\ell, d) = \int_0^{2\pi} \frac{\ell |\cos \theta|}{d} \frac{d\theta}{2\pi} = \frac{\ell}{2\pi d} 4 \int_0^{\pi/2} \cos \theta d\theta$$

$$= \frac{2\ell}{\pi d} [\sin \theta]_0^{\pi/2} = \frac{2\ell}{\pi d}.$$

Several attempts have been made to experimentally determine  $\pi$  by needle-tossing. For a discussion of the relevant statistics and a critical analysis of one of the more accurate (and least believable) needle-tossings, see Badger (1994).

#### Bumping Algorithm

Given a PERMUTATION  $\{p_1, p_2, \dots, p_n\}$  of  $\{1, \dots, n\}$ , the bumping algorithm constructs a standard YOUNG TABLEAU by inserting the  $p_i$  one by one into an already constructed YOUNG TABLEAU. To apply the bumping algorithm, start with  $\{\{p_1\}\}$ , which is a YOUNG TABLEAU. If  $p_1$  through  $p_k$  have already been inserted, then in order to insert  $p_{k+1}$ , start with the first line of the already constructed YOUNG TABLEAU and search for the first element of this line which is greater than  $p_{k+1}$ . If there is no such element, append  $p_{k+1}$  to the first line and stop. If there is such an element (say,  $p_p$ ), exchange  $p_p$  for  $p_{k+1}$ , search the second line using  $p_p$ , and so on.

see also YOUNG TABLEAU

see FIBER BUNDLE

#### Bureau Representation

Gives a MATRIX representation  $b_i$  of a BRAID GROUP in terms of  $(n-1) \times (n-1)$  MATRICES. A  $-t$  always appears in the  $(i, i)$  position.

$$b_1 = \begin{bmatrix} -t & 0 & 0 & \dots & 0 \\ -1 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 1 & \dots & 1 \end{bmatrix} \quad (1)$$

$$b_i = \begin{bmatrix} 1 & \dots & 0 & 0 & \dots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & \dots & -t & 0 & \dots & 0 \\ 0 & \dots & -t & 0 & \dots & 0 \\ 0 & \dots & -1 & 1 & \dots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & \dots & 0 & 0 & \dots & 1 \end{bmatrix} \quad (2)$$

$$b_{n-1} = \begin{bmatrix} 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & -t \\ 0 & 0 & \cdots & 0 & -t \end{bmatrix}. \quad (3)$$

Let  $\Psi$  be the MATRIX PRODUCT of BRAID WORDS, then

$$\frac{\det(I - \Psi)}{1 + t + \cdots + t^{n-1}} = \Delta_L, \quad (4)$$

where  $\Delta_L$  is the ALEXANDER POLYNOMIAL and  $\det$  is the DETERMINANT.

### Burnside's Conjecture

Every non-ABELIAN SIMPLE GROUP has EVEN ORDER.  
 see also ABELIAN GROUP, SIMPLE GROUP

### Burnside's Lemma

Let  $J$  be a FINITE GROUP and the image  $R(J)$  be a representation which is a HOMEOMORPHISM of  $J$  into a PERMUTATION GROUP  $S(X)$ , where  $S(X)$  is the GROUP of all permutations of a SET  $X$ . Define the orbits of  $R(J)$  as the equivalence classes under  $x \sim y$ , which is true if there is some permutation  $p$  in  $R(J)$  such that  $p(x) = y$ . Define the fixed points of  $p$  as the elements  $x$  of  $X$  for which  $p(x) = x$ . Then the AVERAGE number of FIXED POINTS of permutations in  $R(J)$  is equal to the number of orbits of  $R(J)$ .

The LEMMA was apparently known by Cauchy (1845) in obscure form and Frobenius (1887) prior to Burnside's (1900) rediscovery. It was subsequently extended and refined by Pólya (1937) for applications in COMBINATORIAL counting problems. In this form, it is known as PÓLYA ENUMERATION THEOREM.

### Burnside Problem

A problem originating with W. Burnside (1902), who wrote, "A still undecided point in the theory of discontinuous groups is whether the ORDER of a GROUP may be not finite, while the order of every operation it contains is finite." This question would now be phrased as "Can a finitely generated group be infinite while every element in the group has finite order?" (Vaughan-Lee 1990). This question was answered by Golod (1964) when he constructed finitely generated infinite  $p$ -GROUPS. These GROUPS, however, do not have a finite exponent.

Let  $F_r$  be the FREE GROUP of RANK  $r$  and let  $N$  be the SUBGROUP generated by the set of  $n$ th POWERS  $\{g^n | g \in F_r\}$ . Then  $N$  is a normal subgroup of  $F_r$ . We define  $B(r, n) = F_r/N$  to be the QUOTIENT GROUP. We call  $B(r, n)$  the  $r$ -generator Burnside group of exponent  $n$ . It is the largest  $r$ -generator group of exponent  $n$ , in the sense that every other such group is a HOMEOMORPHIC image of  $B(r, n)$ . The Burnside problem is usually stated as: "For which values of  $r$  and  $n$  is  $B(r, n)$  a FINITE GROUP?"

An answer is known for the following values. For  $r = 1$ ,  $B(1, n)$  is a CYCLIC GROUP of ORDER  $n$ . For  $n = 2$ ,  $B(r, 2)$  is an elementary ABELIAN 2-group of ORDER  $2^n$ . For  $n = 3$ ,  $B(r, 3)$  was proved to be finite by Burnside. The ORDER of the  $B(r, 3)$  groups was established by Levi and van der Waerden (1933), namely  $3^a$  where

$$a \equiv r + \binom{r}{2} + \binom{r}{3}, \quad (1)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. For  $n = 4$ ,  $B(r, 4)$  was proved to be finite by Sanov (1940). Groups of exponent four turn out to be the most complicated for which a POSITIVE solution is known. The precise nilpotency class and derived length are known, as are bounds for the ORDER. For example,

$$|B(2, 4)| = 2^{12} \quad (2)$$

$$|B(3, 4)| = 2^{69} \quad (3)$$

$$|B(4, 4)| = 2^{422} \quad (4)$$

$$|B(5, 4)| = 2^{2728}, \quad (5)$$

while for larger values of  $r$  the exact value is not yet known. For  $n = 6$ ,  $B(r, 6)$  was proved to be finite by Hall (1958) with ORDER  $2^a 3^b$ , where

$$a \equiv 1 + (r - 1)3^c \quad (6)$$

$$b \equiv 1 + (r - 1)2^r \quad (7)$$

$$c \equiv r + \binom{r}{2} + \binom{r}{3}. \quad (8)$$

No other Burnside groups are known to be finite. On the other hand, for  $r > 2$  and  $n \geq 665$ , with  $n$  ODD,

$B(r, n)$  is infinite (Novikov and Adjan 1968). There is a similar fact for  $r > 2$  and  $n$  a large POWER of 2.

E. Zelmanov was awarded a FIELDS MEDAL in 1994 for his solution of the “restricted” Burnside problem.

#### Busy Beaver

A busy beaver is an  $n$ -state, 2-symbol, 5-tuple TURING MACHINE which writes the maximum possible number  $BB(n)$  of 1s on an initially blank tape before halting. For  $n = 0, 1, 2, \dots$ ,  $BB(n)$  is given by 0, 1, 4, 6, 13,  $\geq 4098$ ,  $\geq 136612$ ,  $\dots$ . The busy beaver sequence is also known as RADO’S SIGMA FUNCTION.

#### Butterfly Catastrophe

A CATASTROPHE which can occur for four control factors and one behavior axis. The equations

$$\begin{aligned}x &= c(8at^3 + 24t^5) \\ y &= c(-6at^2 - 15t^4)\end{aligned}$$

display such a catastrophe (von Seggern 1993).

## C-Curve

see LÉVY FRACTAL

## C-Determinant

A DETERMINANT appearing in PADÉ APPROXIMANT identities:

$$C_{r/s} = \begin{vmatrix} a_{r-s+1} & a_{r-s+2} & \cdots & a_r \\ \vdots & \vdots & \ddots & \vdots \\ a_r & a_{r+1} & \cdots & a_{r+s-1} \end{vmatrix}.$$

see also PADÉ APPROXIMANT

## C-Matrix

Any SYMMETRIC MATRIX ( $A^T = A$ ) or SKEW SYMMETRIC MATRIX ( $A^T = -A$ )  $C_n$  with diagonal elements 0 and others  $\pm 1$  satisfying

$$CC^T = (n-1)I,$$

where  $I$  is the IDENTITY MATRIX, is known as a  $C$ -matrix (Ball and Coxeter 1987). Examples include

$$C_4 = \begin{bmatrix} 0 & + & + & + \\ - & 0 & - & + \\ - & + & 0 & - \\ - & - & + & 0 \end{bmatrix}$$

$$C_6 = \begin{bmatrix} 0 & + & + & + & + & + \\ + & 0 & + & - & - & + \\ + & + & 0 & + & + & - \\ + & - & + & 0 & + & - \\ + & - & - & + & 0 & + \\ + & + & - & - & + & 0 \end{bmatrix}.$$

## Cactus Fractal

A MANDELBROT SET-like FRACTAL obtained by iterating the map

$$z_{n+1} = z_n^3 + (z_0 - 1)z_n - z_0.$$

see also FRACTAL, JULIA SET, MANDELBROT SET

## Cake Cutting

It is always possible to “fairly” divide a cake among  $n$  people using only vertical cuts. Furthermore, it is possible to cut and divide a cake such that each person believes that *everyone* has received  $1/n$  of the cake according to his own measure. Finally, if there is some piece on which two people disagree, then there is a way of partitioning and dividing a cake such that each participant believes that he has obtained more than  $1/n$  of the cake according to his own measure.

Ignoring the height of the cake, the cake-cutting problem is really a question of fairly dividing a CIRCLE into  $n$  equal AREA pieces using cuts in its plane. One method of proving fair cake cutting to always be possible relies on the FROBENIUS-KÖNIG THEOREM.

see also CIRCLE CUTTING, CYLINDER CUTTING, ENVY-FREE, FROBENIUS-KÖNIG THEOREM, HAM SANDWICH THEOREM, PANCAKE THEOREM, PIZZA THEOREM, SQUARE CUTTING, TORUS CUTTING

## Cal

see WALSH FUNCTION

## Calabi's Triangle

Equilateral Triangle

Calabi's Triangle

The one TRIANGLE in addition to the EQUILATERAL TRIANGLE for which the largest inscribed SQUARE can be inscribed in three different ways. The ratio of the sides to that of the base is given by  $x = 1.55138752455 \dots$  (Sloane's A046095), where

$$x = \frac{1}{3} + \frac{(-23 + 3i\sqrt{237})^{1/3}}{3 \cdot 2^{2/3}} + \frac{11}{3[2(-23 + 3i\sqrt{237})]^{1/3}}$$

is the largest POSITIVE ROOT of

$$2x^3 - 2x^2 - 3x + 2 = 0,$$

which has CONTINUED FRACTION [1, 1, 1, 4, 2, 1, 2, 1, 5, 2, 1, 3, 1, 1, 390, ...] (Sloane's A046096).

## Calabi-Yau Space

A structure into which the 6 extra DIMENSIONS of 10-D string theory curl up.

## Calculus

In general, "a" calculus is an abstract theory developed in a purely formal way.

"The" calculus, more properly called ANALYSIS (or REAL ANALYSIS or, in older literature, INFINITESIMAL ANALYSIS) is the branch of mathematics studying the rate of change of quantities (which can be interpreted as SLOPES of curves) and the length, AREA, and VOLUME of objects. The CALCULUS is sometimes divided into DIFFERENTIAL and INTEGRAL CALCULUS, concerned with DERIVATIVES

$$\frac{d}{dx}f(x)$$

and INTEGRALS

$$\int f(x) dx,$$

respectively.

While ideas related to calculus had been known for some time (Archimedes' EXHAUSTION METHOD was a form of calculus), it was not until the independent work of Newton and Leibniz that the modern elegant tools and ideas of calculus were developed. Even so, many years elapsed until the subject was put on a mathematically rigorous footing by mathematicians such as Weierstraß.

## Calculus of Variations

A branch of mathematics which is a sort of generalization of CALCULUS. Calculus of variations seeks to find the path, curve, surface, etc., for which a given FUNCTION has a STATIONARY VALUE (which, in physical

problems, is usually a MINIMUM or MAXIMUM). Mathematically, this involves finding STATIONARY VALUES of integrals of the form

$$I = \int_b^a f(y, \dot{y}, x) dx. \quad (1)$$

$I$  has an extremum only if the EULER-LAGRANGE DIFFERENTIAL EQUATION is satisfied, i.e., if

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \left( \frac{\partial f}{\partial \dot{y}} \right) = 0. \quad (2)$$

The FUNDAMENTAL LEMMA OF CALCULUS OF VARIATIONS states that, if

$$\int_a^b M(x)h(x) dx = 0 \quad (3)$$

for all  $h(x)$  with CONTINUOUS second PARTIAL DERIVATIVES, then

$$M(x) = 0 \quad (4)$$

on  $(a, b)$ .

### Cannonball Problem

Find a way to stack a SQUARE of cannonballs laid out on the ground into a SQUARE PYRAMID (i.e., find a SQUARE NUMBER which is also SQUARE PYRAMIDAL). This corresponds to solving the DIOPHANTINE EQUATION

$$\sum_{i=1}^k i^2 = \frac{1}{6}k(1+k)(1+2k) = N^2$$

for some pyramid height  $k$ . The only solution is  $k = 24$ ,  $N = 70$ , corresponding to 4900 cannonballs (Ball and Coxeter 1987, Dickson 1952), as conjectured by Lucas (1875, 1876) and proved by Watson (1918).

### Canonical Transformation

see SYMPLECTIC Diffeomorphism

### Cantor Comb

see CANTOR SET

### Cantor-Dedekind Axiom

The points on a line can be put into a ONE-TO-ONE correspondence with the REAL NUMBERS.

see also CARDINAL NUMBER, CONTINUUM HYPOTHESIS, DEDEKIND CUT

### Cantor Diagonal Slash

A clever and rather abstract technique used by Georg Cantor to show that the INTEGERS and REALS cannot be put into a ONE-TO-ONE correspondence (i.e., the INFINITY of REAL NUMBERS is "larger" than the INFINITY of INTEGERS). It proceeds by constructing a new member  $S'$  of a SET from already known members  $S$  by arranging its  $n$ th term to differ from the  $n$ th term of the  $n$ th member of  $S$ . The tricky part is that this is done in such a way that the SET including the new member has a larger CARDINALITY than the original SET  $S$ .

see also CARDINALITY, CONTINUUM HYPOTHESIS, DENUMERABLE SET

#### References

### Cantor Dust

A FRACTAL which can be constructed using STRING REWRITING by creating a matrix three times the size of the current matrix using the rules

```
line 1: "*" -> "*" *, " " -> " "
line 2: "*" -> " " " " -> " "
line 3: "*" -> "*" *, " " -> " "
```

Let  $N_n$  be the number of black boxes,  $L_n$  the length of a side of a white box, and  $A_n$  the fractional AREA of black boxes after the  $n$ th iteration.

$$N_n = 5^n \quad (1)$$

$$L_n = \left(\frac{1}{3}\right)^n = 3^{-n} \quad (2)$$

$$A_n = L_n^2 N_n = \left(\frac{5}{9}\right)^n. \quad (3)$$

The CAPACITY DIMENSION is therefore

$$\begin{aligned} d_{\text{cap}} &= -\lim_{n \rightarrow \infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n \rightarrow \infty} \frac{\ln(5^n)}{\ln(3^{-n})} \\ &= \frac{\ln 5}{\ln 3} = 1.464973521 \dots \end{aligned} \quad (4)$$

see also BOX FRACTAL, SIERPIŃSKI CARPET, SIERPIŃSKI SIEVE

**Cantor's Equation**

$$\omega^\epsilon = \epsilon,$$

where  $\omega$  is an ORDINAL NUMBER and  $\epsilon$  is an INACCESSIBLE CARDINAL.

see also INACCESSIBLE CARDINAL, ORDINAL NUMBER

References

- Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, p. 274, 1996.

**Cantor Function**

The function whose values are

$$\frac{1}{2} \left( \frac{c_1}{2} + \dots + \frac{c_{m-1}}{2^{m-1}} + \frac{2}{2^m} \right)$$

for any number between

$$a \equiv \frac{c_1}{3} + \dots + \frac{c_{m-1}}{3^{m-1}} + \frac{1}{3^m}$$

and

$$b \equiv \frac{c_1}{3} + \dots + \frac{c_{m-1}}{3^{m-1}} + \frac{2}{3^m}.$$

Chalice (1991) shows that any real-values function  $F(x)$  on  $[0, 1]$  which is MONOTONE INCREASING and satisfies

1.  $F(0) = 0$ ,
2.  $F(x/3) = F(x)/2$ ,
3.  $F(1-x) = 1 - F(x)$

is the Cantor function.

see also CANTOR SET, DEVIL'S STAIRCASE

References

- Chalice, D. R. "A Characterization of the Cantor Function." *Amer. Math. Monthly* **98**, 255–258, 1991.  
 Wagon, S. "The Cantor Function" and "Complex Cantor Sets." §4.2 and 5.1 in *Mathematica in Action*. New York: W. H. Freeman, pp. 102–108 and 143–149, 1991.

**Cantor's Paradox**

The SET of all SETS is its own POWER SET. Therefore, the CARDINALITY of the SET of all SETS must be bigger than itself.

see also CANTOR'S THEOREM, POWER SET

**Cantor Set**

The Cantor set ( $T_\infty$ ) is given by taking the interval  $[0,1]$  (set  $T_0$ ), removing the middle third ( $T_1$ ), removing the middle third of each of the two remaining pieces ( $T_2$ ), and continuing this procedure ad infinitum. It is therefore the set of points in the INTERVAL  $[0,1]$  whose ternary expansions do not contain 1, illustrated below.

This produces the SET of REAL NUMBERS  $\{x\}$  such that

$$x = \frac{c_1}{3} + \dots + \frac{c_n}{3^n} + \dots, \quad (1)$$

where  $c_n$  may equal 0 or 2 for each  $n$ . This is an infinite, PERFECT SET. The total length of the LINE SEGMENTS in the  $n$ th iteration is

$$\ell_n = \left(\frac{2}{3}\right)^n, \quad (2)$$

and the number of LINE SEGMENTS is  $N_n = 2^n$ , so the length of each element is

$$\epsilon_n \equiv \frac{\ell}{N} = \left(\frac{1}{3}\right)^n \quad (3)$$

and the CAPACITY DIMENSION is

$$\begin{aligned} d_{\text{cap}} &\equiv - \lim_{\epsilon \rightarrow 0^+} \frac{\ln N}{\ln \epsilon} = - \lim_{n \rightarrow \infty} \frac{n \ln 2}{-n \ln 3} \\ &= \frac{\ln 2}{\ln 3} = 0.630929\dots \end{aligned} \quad (4)$$

The Cantor set is nowhere DENSE, so it has LEBESGUE MEASURE 0.

A general Cantor set is a CLOSED SET consisting entirely of BOUNDARY POINTS. Such sets are UNCOUNTABLE and may have 0 or POSITIVE LEBESGUE MEASURE. The Cantor set is the only totally disconnected, perfect, COMPACT METRIC SPACE up to a HOMEOMORPHISM (Willard 1970).

 Willard, S. §30.4 in *General Topology*. Reading, MA: Addison-Wesley, 1970.

**Cantor Square Fractal**

A FRACTAL which can be constructed using STRING RE-WRITING by creating a matrix three times the size of the current matrix using the rules

line 1: "\*"-">"\*\*\*", " ">" "  
 line 2: "\*"-">"\* \*", " ">" "  
 line 3: "\*"-">"\*\*\*", " ">" "

The first few steps are illustrated above.

The size of the unit element after the  $n$ th iteration is

$$L_n = \left(\frac{1}{3}\right)^n$$

and the number of elements is given by the RECUR-RANCE RELATION

$$N_n = 4N_{n-1} + 5(9^n)$$

where  $N_1 \equiv 5$ , and the first few numbers of elements are 5, 65, 665, 6305, . . . . Expanding out gives

$$N_n = 5 \sum_{k=0}^n 4^{n-k} 9^{k-1} = 9^n - 4^n.$$

The CAPACITY DIMENSION is therefore

$$\begin{aligned} D &= - \lim_{n \rightarrow \infty} \frac{\ln N_n}{\ln L_n} = - \lim_{n \rightarrow \infty} \frac{\ln(9^n - 4^n)}{\ln(3^{-n})} \\ &= - \lim_{n \rightarrow \infty} \frac{\ln(9^n)}{\ln(3^{-n})} = \frac{\ln 9}{\ln 3} = \frac{2 \ln 3}{\ln 3} = 2. \end{aligned}$$

Since the DIMENSION of the filled part is 2 (i.e., the SQUARE is completely filled), Cantor's square fractal is not a true FRACTAL.

see also BOX FRACTAL, CANTOR DUST

### Cantor's Theorem

The CARDINAL NUMBER of any set is lower than the CARDINAL NUMBER of the set of all its subsets. A COROLLARY is that there is no highest  $\aleph$  (ALEPH).

see also CANTOR'S PARADOX

### Cap

see CROSS-CAP, SPHERICAL CAP

### Capacity

see TRANSFINITE DIAMETER

### Capacity Dimension

A DIMENSION also called the FRACTAL DIMENSION, HAUSDORFF DIMENSION, and HAUSDORFF-BESICOVITCH DIMENSION in which nonintegral values are permitted. Objects whose capacity dimension is different from their TOPOLOGICAL DIMENSION are called FRACTALS. The capacity dimension of a compact METRIC SPACE  $X$  is a REAL NUMBER  $d_{\text{capacity}}$  such that if  $n(\epsilon)$  denotes the minimum number of open sets of diameter less than or equal to  $\epsilon$ , then  $n(\epsilon)$  is proportional to  $\epsilon^{-D}$  as  $\epsilon \rightarrow 0$ . Explicitly,

$$d_{\text{capacity}} \equiv - \lim_{\epsilon \rightarrow 0^+} \frac{\ln N}{\ln \epsilon}$$

(if the limit exists), where  $N$  is the number of elements forming a finite COVER of the relevant METRIC SPACE and  $\epsilon$  is a bound on the diameter of the sets involved (informally,  $\epsilon$  is the size of each element used to cover the set, which is taken to approach 0). If each element of a FRACTAL is equally likely to be visited, then  $d_{\text{capacity}} = d_{\text{information}}$ , where  $d_{\text{information}}$  is the INFORMATION DIMENSION. The capacity dimension satisfies

$$d_{\text{correlation}} \leq d_{\text{information}} \leq d_{\text{capacity}}$$

where  $d_{\text{correlation}}$  is the CORRELATION DIMENSION, and is conjectured to be equal to the LYAPUNOV DIMENSION. see also CORRELATION EXPONENT, DIMENSION, HAUSDORFF DIMENSION, KAPLAN-YORKE DIMENSION

### Carathéodory Derivative

A function  $f$  is Carathéodory differentiable at  $a$  if there exists a function  $\phi$  which is CONTINUOUS at  $a$  such that

$$f(x) - f(a) = \phi(x)(x - a).$$

Every function which is Carathéodory differentiable is also FRÉCHET DIFFERENTIABLE.

see also DERIVATIVE, FRÉCHET DERIVATIVE

### Carathéodory's Fundamental Theorem

Each point in the CONVEX HULL of a set  $S$  in  $\mathbb{R}^n$  is in the convex combination of  $n + 1$  or fewer points of  $S$ .

see CUBIC EQUATION

### Cardinal Number

In informal usage, a cardinal number is a number used in counting (a COUNTING NUMBER), such as 1, 2, 3, . . .

Formally, a cardinal number is a type of number defined in such a way that any method of counting SETS using it gives the same result. (This is not true for the ORDINAL NUMBERS.) In fact, the cardinal numbers are obtained by collecting all ORDINAL NUMBERS which are obtainable by counting a given set. A set has  $\aleph_0$  (ALEPH-0) members if it can be put into a ONE-TO-ONE correspondence with the finite ORDINAL NUMBERS.

Two sets are said to have the same cardinal number if all the elements in the sets can be paired off ONE-TO-ONE. An INACCESSIBLE CARDINAL cannot be expressed in terms of a smaller number of smaller cardinals.

### Cardinality

see CARDINAL NUMBER

### Cardioid

The curve given by the POLAR equation

$$r = a(1 + \cos \theta), \quad (1)$$

sometimes also written

$$r = 2b(1 + \cos \theta), \quad (2)$$

where  $b \equiv a/2$ , the CARTESIAN equation

$$(x^2 + y^2 - ax)^2 = a^2(x^2 + y^2), \quad (3)$$

and the parametric equations

$$x = a \cos t(1 + \cos t) \quad (4)$$

$$y = a \sin t(1 + \cos t). \quad (5)$$

The cardioid is a degenerate case of the LIMAÇON. It is also a 1-CUSPED EPICYCLOID (with  $r = R$ ) and is the CAUSTIC formed by rays originating at a point on the circumference of a CIRCLE and reflected by the CIRCLE.

The name cardioid was first used by de Castillon in *Philosophical Transactions of the Royal Society* in 1741. Its ARC LENGTH was found by La Hire in 1708. There are exactly three PARALLEL TANGENTS to the cardioid with any given gradient. Also, the TANGENTS at the ends of any CHORD through the CUSP point are at RIGHT ANGLES. The length of any CHORD through the CUSP point is  $2a$ .

The cardioid may also be generated as follows. Draw a CIRCLE  $C$  and fix a point  $A$  on it. Now draw a set of CIRCLES centered on the CIRCUMFERENCE of  $C$  and passing through  $A$ . The ENVELOPE of these CIRCLES is then a cardioid (Pedoe 1995). Let the CIRCLE  $C$  be centered at the origin and have RADIUS 1, and let the fixed point be  $A = (1, 0)$ . Then the RADIUS of a CIRCLE centered at an ANGLE  $\theta$  from  $(1, 0)$  is

$$\begin{aligned} r^2 &= (0 - \cos \theta)^2 + (1 - \sin \theta)^2 \\ &= \cos^2 \theta + 1 - 2 \sin \theta + \sin^2 \theta \\ &= 2(1 - \sin \theta). \end{aligned} \quad (6)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s = \int_0^t 2 |\cos(\frac{1}{2}t)| dt = 4a \sin(\frac{1}{2}\theta) \quad (7)$$

$$\kappa = \frac{3 |\sec(\frac{1}{2}\theta)|}{4a} \quad (8)$$

$$\phi = \frac{3}{2}\theta. \quad (9)$$

As usual, care must be taken in the evaluation of  $s(t)$  for  $t > \pi$ . Since (7) comes from an integral involving the

ABSOLUTE VALUE of a function, it must be monotonic increasing. Each QUADRANT can be treated correctly by defining

$$n = \left\lfloor \frac{t}{\pi} \right\rfloor + 1, \quad (10)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, giving the formula

$$s(t) = (-1)^{1+[n \pmod{2}]} 4 \sin(\tfrac{1}{2}t) + 8 \lfloor \tfrac{1}{2}n \rfloor. \quad (11)$$

The PERIMETER of the curve is

$$\begin{aligned} L &= \int_0^{2\pi} |2a \cos(\tfrac{1}{2}\theta)| d\theta = 4a \int_0^\pi \cos(\tfrac{1}{2}\theta) d\theta \\ &= 4a \int_0^{\pi/2} \cos \phi (2 d\phi) = 8a \int_0^{\pi/2} \cos \phi d\phi \\ &= 8a [\sin \phi]_0^{\pi/2} = 8a. \end{aligned} \quad (12)$$

The AREA is

$$\begin{aligned} A &= \tfrac{1}{2} \int_0^{2\pi} r^2 d\theta = \tfrac{1}{2} a^2 \int_0^{2\pi} (1 + 2 \cos \theta + \cos^2 \theta) d\theta \\ &= \tfrac{1}{2} a^2 \int_0^{2\pi} \{1 + 2 \cos \theta + \tfrac{1}{2}[1 + \cos(2\theta)]\} d\theta \\ &= \tfrac{1}{2} a^2 \int_0^{2\pi} [\tfrac{3}{2} + 2 \cos \theta + \tfrac{1}{2} \cos(2\theta)] d\theta \\ &= \tfrac{1}{2} a^2 [\tfrac{3}{2}\theta + 2 \sin \theta + \tfrac{1}{4} \sin(2\theta)]_0^{2\pi} = \tfrac{3}{2} \pi a^2. \end{aligned} \quad (13)$$

#### Cardioid Caustic

The CATACAUSTIC of a CARDIOID for a RADIANT POINT at the CUSP is a NEPHROID. The CATACAUSTIC for PARALLEL rays crossing a CIRCLE is a CARDIOID.

#### Cardioid Evolute

$$\begin{aligned} x &= \tfrac{2}{3}a + \tfrac{1}{3}a \cos \theta (1 - \cos \theta) \\ y &= \tfrac{1}{3}a \sin \theta (1 - \cos \theta). \end{aligned}$$

This is a mirror-image CARDIOID with  $a' = a/3$ .

#### Cardioid Inverse Curve

If the CUSP of the cardioid is taken as the INVERSION CENTER, the cardioid inverts to a PARABOLA.

#### Cardioid Involute

$$\begin{aligned} x &= 2a + 3a \cos \theta (1 - \cos \theta) \\ y &= 3a \sin \theta (1 - \cos \theta). \end{aligned}$$

This is a mirror-image CARDIOID with  $a' = 3a$ .

#### Cardioid Pedal Curve

The PEDAL CURVE of the CARDIOID where the PEDAL POINT is the CUSP is CAYLEY'S SEXTIC.

#### Cards

Cards are a set of  $n$  rectangular pieces of cardboard with markings on one side and a uniform pattern on the other. The collection of all cards is called a "deck," and a normal deck of cards consists of 52 cards of four different "suits." The suits are called clubs (♣), diamonds (♦), hearts (♥), and spades (♠). Spades and clubs are

colored black, while hearts and diamonds are colored red. The cards of each suit are numbered 1 through 13, where the special terms ace (1), jack (11), queen (12), and king (13) are used instead of numbers 1 and 11-13.

The randomization of the order of cards in a deck is called SHUFFLING. Cards are used in many gambling games (such as POKER), and the investigation of the probabilities of various outcomes in card games was one of the original motivations for the development of modern PROBABILITY theory.

see also BRIDGE CARD GAME, CLOCK SOLITAIRE, COIN, COIN TOSSING, DICE, POKER, SHUFFLE

### Carleman's Inequality

Let  $\{a_i\}_{i=1}^n$  be a SET of POSITIVE numbers. Then the GEOMETRIC MEAN and ARITHMETIC MEAN satisfy

$$\sum_{i=1}^n (a_1 a_2 \cdots a_i)^{1/i} \leq \frac{e}{n} \sum_{i=1}^n a_i.$$

Here, the constant  $e$  is the best possible, in the sense that counterexamples can be constructed for any stricter INEQUALITY which uses a smaller constant.

see also ARITHMETIC MEAN,  $e$ , GEOMETRIC MEAN

### Carlson-Levin Constant

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Assume that  $f$  is a NONNEGATIVE REAL function on  $[0, \infty)$  and that the two integrals

$$\int_0^\infty x^{p-1-\lambda} [f(x)]^p dx \quad (1)$$

$$\int_0^\infty x^{q-1+\mu} [f(x)]^q dx \quad (2)$$

exist and are FINITE. If  $p = q = 2$  and  $\lambda = \mu = 1$ , Carlson (1934) determined

$$\int_0^\infty f(x) dx \leq \sqrt{\pi} \left( \int_0^\infty [f(x)]^2 dx \right)^{1/4} \times \left( \int_0^\infty x^2 [f(x)]^2 dx \right)^{1/4} \quad (3)$$

and showed that  $\sqrt{\pi}$  is the best constant (in the sense that counterexamples can be constructed for any stricter

INEQUALITY which uses a smaller constant). For the general case

$$\int_0^\infty f(x) dx \leq C \left( \int_0^\infty x^{p-1-\lambda} [f(x)]^p dx \right)^s \times \left( \int_0^\infty x^{q-1+\mu} [f(x)]^q dx \right)^t, \quad (4)$$

and Levin (1948) showed that the best constant

$$C = \frac{1}{(ps)^s (qt)^t} \left[ \frac{\Gamma\left(\frac{s}{\alpha}\right) \Gamma\left(\frac{t}{\alpha}\right)}{(\lambda + \mu) \Gamma\left(\frac{s+t}{\alpha}\right)} \right]^\alpha, \quad (5)$$

where

$$s \equiv \frac{\mu}{p\mu + q\lambda} \quad (6)$$

$$t \equiv \frac{\lambda}{p\mu + q\lambda} \quad (7)$$

$$\alpha \equiv 1 - s - t \quad (8)$$

and  $\Gamma(z)$  is the GAMMA FUNCTION.

### Carlyle Circle

Consider a QUADRATIC EQUATION  $x^2 - sx + p = 0$  where  $s$  and  $p$  denote signed lengths. The CIRCLE which has

the points  $A = (0, 1)$  and  $B = (s, p)$  as a DIAMETER is then called the Carlyle circle  $C_{s,p}$  of the equation. The CENTER of  $C_{s,p}$  is then at the MIDPOINT of  $AB$ ,  $M = (s/2, (1+p)/2)$ , which is also the MIDPOINT of  $S = (s, 0)$  and  $Y = (0, 1+p)$ . Call the points at which  $C_{s,p}$  crosses the  $x$ -AXIS  $H_1 = (x_1, 0)$  and  $H_2 = (x_2, 0)$  (with  $x_1 \geq x_2$ ). Then

$$s = x_1 + x_2$$

$$p = x_1 x_2$$

$$(x - x_1)(x - x_2) = x^2 - sx + p,$$

so  $x_1$  and  $x_2$  are the ROOTS of the quadratic equation. *see also* 257-GON, 65537-GON, HEPTADECAGON, PENTAGON

#### Carmichael Function

$\lambda(n)$  is the LEAST COMMON MULTIPLE (LCM) of all the FACTORS of the TOTIENT FUNCTION  $\phi(n)$ , except that if  $8|n$ , then  $2^{\alpha-2}$  is a FACTOR instead of  $2^{\alpha-1}$ .

$$\lambda(n) = \begin{cases} \phi(n) & \text{for } n = p^\alpha, p = 2 \text{ and } \alpha \leq 2, \text{ or } p \geq 3 \\ \frac{1}{2}\phi(n) & \text{for } n = 2^\alpha \text{ and } \alpha \geq 3 \\ \text{LCM}[\lambda(p_i^{\alpha_i})]_i & \text{for } n = \prod_i p_i^{\alpha_i}. \end{cases}$$

Some special values are

$$\lambda(1) = 1$$

$$\lambda(2) = 1$$

$$\lambda(4) = 2$$

$$\lambda(2^r) = 2^{r-2}$$

for  $r \geq 3$ , and

$$\lambda(p^r) = \phi(p^r)$$

for  $p$  an ODD PRIME and  $r \geq 1$ . The ORDER of  $a \pmod{n}$  is at most  $\lambda(n)$  (Ribenboim 1989). The values of  $\lambda(n)$  for the first few  $n$  are 1, 1, 2, 2, 2, 4, 2, 6, 4, 10, 2, 12, ... (Sloane's A011773).

#### Carmichael Number

A Carmichael number is an ODD COMPOSITE NUMBER  $n$  which satisfies FERMAT'S LITTLE THEOREM

$$a^{n-1} - 1 \equiv 0 \pmod{n}$$

for every choice of  $a$  satisfying  $(a, n) = 1$  (i.e.,  $a$  and  $n$  are RELATIVELY PRIME) with  $1 < a < n$ . A Carmichael number is therefore a PSEUDOPRIME to any base. Carmichael numbers therefore cannot be found to be COMPOSITE using FERMAT'S LITTLE THEOREM. However, if  $(a, n) \neq 1$ , the congruence of FERMAT'S LITTLE THEOREM is sometimes NONZERO, thus identifying a Carmichael number  $n$  as COMPOSITES.

Carmichael numbers are sometimes called ABSOLUTE PSEUDOPRIMES and also satisfy KORSELT'S CRITERION. R. D. Carmichael first noted the existence of such numbers in 1910, computed 15 examples, and conjectured that there were infinitely many (a fact finally proved by Alford *et al.* 1994).

The first few Carmichael numbers are 561, 1105, 1729, 2465, 2821, 6601, 8911, 10585, 15841, 29341, ... (Sloane's A002997). Carmichael numbers have at least three PRIME FACTORS. For Carmichael numbers with exactly three PRIME FACTORS, once one of the PRIMES has been specified, there are only a finite number of Carmichael numbers which can be constructed. Numbers of the form  $(6k+1)(12k+1)(18k+1)$  are Carmichael numbers if each of the factors is PRIME (Korselt 1899, Ore 1988, Guy 1994). This can be seen since for

$$N \equiv (6k+1)(12k+1)(18k+1) = 1296k^3 + 396k^2 + 36k + 1,$$

$N - 1$  is a multiple of  $36k$  and the LEAST COMMON MULTIPLE of  $6k$ ,  $12k$ , and  $18k$  is  $36k$ , so  $a^{N-1} \equiv 1$  modulo each of the PRIMES  $6k+1$ ,  $12k+1$ , and  $18k+1$ , hence  $a^{N-1} \equiv 1$  modulo their product. The first few such Carmichael numbers correspond to  $k = 1, 6, 35, 45, 51, 55, 56, \dots$  and are 1729, 294409, 56052361, 118901521, ... (Sloane's A046025). The largest known Carmichael number of this form was found by H. Dubner in 1996 and has 1025 digits.

The smallest Carmichael numbers having 3, 4, ... factors are  $561 = 3 \times 11 \times 17$ ,  $41041 = 7 \times 11 \times 13 \times 41$ ,  $825265$ ,  $321197185$ , ... (Sloane's A006931). In total, there are only 43 Carmichael numbers  $< 10^6$ ,  $2163 \leq 2.5 \times 10^{10}$ ,  $105,212 \leq 10^{15}$ , and  $246,683 \leq 10^{16}$  (Pinch 1993). Let  $C(n)$  denote the number of Carmichael numbers less than  $n$ . Then, for sufficiently large  $n$  ( $n \sim 10^7$  from numerical evidence),

$$C(n) \sim n^{2/7}$$

(Alford *et al.* 1994).

The Carmichael numbers have the following properties:

1. If a PRIME  $p$  divides the Carmichael number  $n$ , then  $n \equiv 1 \pmod{p-1}$  implies that  $n \equiv p \pmod{p(p-1)}$ .
2. Every Carmichael number is SQUAREFREE.
3. An ODD COMPOSITE SQUAREFREE number  $n$  is a Carmichael number IFF  $n$  divides the DENOMINATOR of the BERNOULLI NUMBER  $B_{n-1}$ .

#### Carmichael Sequence

A FINITE, INCREASING SEQUENCE of INTEGERS  $\{a_1, \dots, a_m\}$  such that

$$(a_i - 1) | (a_1 \cdots a_{i-1})$$

for  $i = 1, \dots, m$ , where  $m|n$  indicates that  $m$  DIVIDES  $n$ . A Carmichael sequence has exclusive EVEN or ODD elements. There are infinitely many Carmichael sequences for every order.

#### Carmichael's Theorem

If  $a$  and  $n$  are RELATIVELY PRIME so that the GREATEST COMMON DENOMINATOR  $\text{GCD}(a, n) = 1$ , then

$$a^{\lambda(n)} \equiv 1 \pmod{n},$$

where  $\lambda$  is the CARMICHAEL FUNCTION.

#### Carmichael's Totient Function Conjecture

It is thought that the TOTIENT VALENCE FUNCTION  $N_\phi(m) \geq 2$  (i.e., the TOTIENT VALENCE FUNCTION never takes the value 1). This assertion is called Carmichael's totient function conjecture and is equivalent to the statement that there exists an  $m \neq n$  such that  $\phi(n) = \phi(m)$  (Ribenoim 1996, pp. 39–40). Any counterexample to the conjecture must have more than 10,000 DIGITS (Conway and Guy 1996). Recently, the conjecture was reportedly proven by F. Saidak in November, 1997 with a proof short enough to fit on a postcard.

**Carotid-Kundalini Fractal**

A fractal-like structure is produced for  $x < 0$  by superposing plots of CAROTID-KUNDALINI FUNCTIONS  $CK_n$  of different orders  $n$ . The region  $-1 < x < 0$  is called FRACTAL LAND by Pickover (1995), the central region the GAUSSIAN MOUNTAIN RANGE, and the region  $x > 0$  OSCILLATION LAND. The plot above shows  $n = 1$  to 25. Gaps in FRACTAL LAND occur whenever

$$x \cos^{-1} x = 2\pi \frac{p}{q}$$

for  $p$  and  $q$  RELATIVELY PRIME INTEGERS. At such points  $x$ , the functions assume the  $[(q+1)/2]$  values

$\cos(2\pi r/q)$  for  $r = 0, 1, \dots, [q/2]$ , where  $[z]$  is the CEILING FUNCTION and  $\lfloor z \rfloor$  is the FLOOR FUNCTION.

## Cartesian Coordinates

Cartesian coordinates are rectilinear 2-D or 3-D coordinates (and therefore a special case of CURVILINEAR COORDINATES) which are also called RECTANGULAR COORDINATES. The three axes of 3-D Cartesian coordinates, conventionally denoted the  $x$ -,  $y$ -, and  $z$ -AXES (a NOTATION due to Descartes) are chosen to be linear and mutually PERPENDICULAR. In 3-D, the coordinates  $x$ ,  $y$ , and  $z$  may lie anywhere in the INTERVAL  $(-\infty, \infty)$ .

The SCALE FACTORS of Cartesian coordinates are all unity,  $h_i = 1$ . The LINE ELEMENT is given by

$$ds = dx \hat{\mathbf{x}} + dy \hat{\mathbf{y}} + dz \hat{\mathbf{z}}, \quad (1)$$

and the VOLUME ELEMENT by

$$dV = dx dy dz. \quad (2)$$

The GRADIENT has a particularly simple form,

$$\nabla \equiv \hat{\mathbf{x}} \frac{\partial}{\partial x} + \hat{\mathbf{y}} \frac{\partial}{\partial y} + \hat{\mathbf{z}} \frac{\partial}{\partial z}, \quad (3)$$

as does the LAPLACIAN

$$\nabla^2 \equiv \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}. \quad (4)$$

The LAPLACIAN is

$$\begin{aligned} \nabla^2 \mathbf{F} &\equiv \nabla \cdot (\nabla \mathbf{F}) = \frac{\partial^2 \mathbf{F}}{\partial x^2} + \frac{\partial^2 \mathbf{F}}{\partial y^2} + \frac{\partial^2 \mathbf{F}}{\partial z^2} \\ &= \hat{\mathbf{x}} \left( \frac{\partial^2 F_x}{\partial x^2} + \frac{\partial^2 F_x}{\partial y^2} + \frac{\partial^2 F_x}{\partial z^2} \right) \\ &\quad + \hat{\mathbf{y}} \left( \frac{\partial^2 F_y}{\partial x^2} + \frac{\partial^2 F_y}{\partial y^2} + \frac{\partial^2 F_y}{\partial z^2} \right) \\ &\quad + \hat{\mathbf{z}} \left( \frac{\partial^2 F_z}{\partial x^2} + \frac{\partial^2 F_z}{\partial y^2} + \frac{\partial^2 F_z}{\partial z^2} \right). \end{aligned} \quad (5)$$

The DIVERGENCE is

$$\nabla \cdot \mathbf{F} = \frac{\partial F_x}{\partial x} + \frac{\partial F_y}{\partial y} + \frac{\partial F_z}{\partial z}, \quad (6)$$

and the CURL is

$$\begin{aligned} \nabla \times \mathbf{F} &= \begin{vmatrix} \hat{\mathbf{x}} & \hat{\mathbf{y}} & \hat{\mathbf{z}} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ F_x & F_y & F_z \end{vmatrix} \\ &= \left( \frac{\partial F_z}{\partial y} - \frac{\partial F_y}{\partial z} \right) \hat{\mathbf{x}} + \left( \frac{\partial F_x}{\partial z} - \frac{\partial F_z}{\partial x} \right) \hat{\mathbf{y}} \\ &\quad + \left( \frac{\partial F_y}{\partial x} - \frac{\partial F_x}{\partial y} \right) \hat{\mathbf{z}}. \end{aligned} \quad (7)$$

The GRADIENT of the DIVERGENCE is

$$\begin{aligned} \nabla(\nabla \cdot \mathbf{u}) &= \begin{bmatrix} \frac{\partial}{\partial x} \left( \frac{\partial u_x}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z} \right) \\ \frac{\partial}{\partial y} \left( \frac{\partial u_x}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z} \right) \\ \frac{\partial}{\partial z} \left( \frac{\partial u_x}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z} \right) \end{bmatrix} \\ &= \begin{bmatrix} \frac{\partial}{\partial x} \\ \frac{\partial}{\partial y} \\ \frac{\partial}{\partial z} \end{bmatrix} \left( \frac{\partial u_x}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z} \right). \end{aligned} \quad (8)$$

LAPLACE'S EQUATION is separable in Cartesian coordinates.

## Cartesian Ovals

A curve consisting of two ovals which was first studied by Descartes in 1637. It is the locus of a point  $P$  whose distances from two FOCI  $F_1$  and  $F_2$  in two-center BIPOlar COORDINATES satisfy

$$mr \pm nr' = k, \quad (1)$$

where  $m, n$  are POSITIVE INTEGERS,  $k$  is a POSITIVE real, and  $r$  and  $r'$  are the distances from  $F_1$  and  $F_2$ . If  $m = n$ , the oval becomes an an ELLIPSE. In CARTESIAN COORDINATES, the Cartesian ovals can be written

$$m\sqrt{(x-a)^2 + y^2} + n\sqrt{(x+a)^2 + y^2} = k^2 \quad (2)$$

$$\begin{aligned} (x^2 + y^2 + a^2)(m^2 - n^2) - 2ax(m^2 + n^2) - k^2 \\ = -2n\sqrt{(x+a)^2 + y^2}, \end{aligned} \quad (3)$$

$$\begin{aligned} [(m^2 - n^2)(x^2 + y^2 + a^2) - 2ax(m^2 + n^2)]^2 \\ = 2(m^2 + n^2)(n^2 + y^2 + a^2) - 4ax(m^2 - n^2) - k^2. \end{aligned} \quad (4)$$

Now define

$$b \equiv m^2 - n^2 \quad (5)$$

$$c \equiv m^2 + n^2, \quad (6)$$

and set  $a = 1$ . Then

$$[b(x^2 + y^2) - 2cx + b]^2 + 4bx + k^2 - 2c = 2c(x^2 + y^2). \quad (7)$$

If  $c'$  is the distance between  $F_1$  and  $F_2$ , and the equation

$$r + mr' = a \quad (8)$$

is used instead, an alternate form is

$$[(1-m^2)(x^2+y^2)+2m^2c'x+a'^2-m^2c'^2]^2 = 4a'^2(x^2+y^2). \quad (9)$$

The curves possess three FOCI. If  $m = 1$ , one Cartesian oval is a central CONIC, while if  $m = a/c$ , then the curve is a LIMAÇON and the inside oval touches the outside one. Cartesian ovals are ANALLAGMATIC CURVES.

### Cassini Ovals

The curves, also called CASSINI ELLIPSES, described by a point such that the product of its distances from two fixed points a distance  $2a$  apart is a constant  $b^2$ . The shape of the curve depends on  $b/a$ . If  $a < b$ , the curve is a single loop with an OVAL (left figure above) or dog bone (second figure) shape. The case  $a = b$  produces a LEMNISCATE (third figure). If  $a > b$ , then the curve consists of two loops (right figure). The curve was first investigated by Cassini in 1680 when he was studying the relative motions of the Earth and the Sun. Cassini believed that the Sun traveled around the Earth on one of these ovals, with the Earth at one FOCUS of the oval.

Cassini ovals are ANALLAGMATIC CURVES. The Cassini ovals are defined in two-center BIPOLAR COORDINATES by the equation

$$r_1 r_2 = b^2, \quad (1)$$

with the origin at a FOCUS. Even more incredible curves are produced by the locus of a point the product of whose distances from 3 or more fixed points is a constant.

The Cassini ovals have the CARTESIAN equation

$$[(x-a)^2 + y^2][(x+a)^2 + y^2] = b^4 \quad (2)$$

or the equivalent form

$$(x^2 + y^2 + a^2)^2 - 4a^2 x^2 = b^4 \quad (3)$$

and the polar equation

$$r^4 + a^4 - 2a^2 r^2 \cos(2\theta) = b^4. \quad (4)$$

Solving for  $r^2$  using the QUADRATIC EQUATION gives

$$\begin{aligned} r^2 &= \frac{2a^2 \cos(2\theta) + \sqrt{4a^4 \cos^2(2\theta) - 4(a^4 - b^4)}}{2} \\ &= a^2 \cos(2\theta) + \sqrt{a^4 \cos^2(2\theta) + b^4 - a^4} \\ &= a^2 \cos(2\theta) + \sqrt{a^4 [\cos^2(2\theta) - 1] + b^4} \\ &= a^2 \cos(2\theta) + \sqrt{b^4 - a^4 \sin^2(2\theta)} \\ &= a^2 \left[ \cos(2\theta) + \sqrt{\left(\frac{b}{a}\right)^4 - \sin^2(2\theta)} \right]. \end{aligned} \quad (5)$$

If  $a < b$ , the curve has AREA

$$A = \frac{1}{2} r^2 d\theta = 2\left(\frac{1}{2}\right) \int_{-\pi/4}^{\pi/4} r^2 d\theta = a^2 + b^2 E\left(\frac{a^4}{b^4}\right), \quad (6)$$

where the integral has been done over half the curve and then multiplied by two and  $E(x)$  is the complete ELLIPTIC INTEGRAL OF THE SECOND KIND. If  $a = b$ , the curve becomes

$$r^2 = a^2 [\cos(2\theta) + \sqrt{1 - \sin^2 \theta}] = 2a^2 \cos(2\theta), \quad (7)$$

which is a LEMNISCATE having AREA

$$A = 2a^2 \quad (8)$$

(two loops of a curve  $\sqrt{2}$  the linear scale of the usual lemniscate  $r^2 = a^2 \cos(2\theta)$ , which has area  $A = a^2/2$  for each loop). If  $a > b$ , the curve becomes two disjoint ovals with equations

$$r = \pm a \sqrt{\cos(2\theta) \pm \sqrt{\left(\frac{b}{a}\right)^4 - \sin^2(2\theta)}}, \quad (9)$$

where  $\theta \in [-\theta_0, \theta_0]$  and

$$\theta_0 \equiv \frac{1}{2} \sin^{-1} \left[ \left(\frac{b}{a}\right)^2 \right]. \quad (10)$$

#### Cassini Surface

The QUARTIC SURFACE obtained by replacing the constant  $c$  in the equation of the CASSINI OVALS

$$[(x - a)^2 + y^2][(x + a)^2 + y^2] = c^2 \quad (1)$$

by  $c = z^2$ , obtaining

$$[(x - a)^2 + y^2][(x + a)^2 + y^2] = z^4. \quad (2)$$

As can be seen by letting  $y = 0$  to obtain

$$(x^2 - a^2)^2 = z^4 \quad (3)$$

$$x^2 + z^2 = a^2, \quad (4)$$

the intersection of the surface with the  $y = 0$  PLANE is a CIRCLE of RADIUS  $a$ .

### Casting Out Nines

An elementary check of a MULTIPLICATION which makes use of the CONGRUENCE  $10^n \equiv 1 \pmod{9}$  for  $n \geq 2$ . From this CONGRUENCE, a MULTIPLICATION  $ab = c$  must give

$$a \equiv \sum a_i = a^*$$

$$b \equiv \sum b_i = b^*$$

$$c \equiv \sum c_i = c^*,$$

so  $ab \equiv a^*b^*$  must be  $\equiv c^* \pmod{9}$ . Casting out nines is sometimes also called "the HINDU CHECK."

### Catalan's Conjecture

8 and 9 ( $2^3$  and  $3^2$ ) are the only consecutive POWERS (excluding 0 and 1), i.e., the only solution to CATALAN'S DIOPHANTINE PROBLEM. Solutions to this problem (CATALAN'S DIOPHANTINE PROBLEM) are equivalent to solving the simultaneous DIOPHANTINE EQUATIONS

$$X^2 - Y^3 = 1$$

$$X^3 - Y^2 = 1.$$

This CONJECTURE has not yet been proved or refuted, although it has been shown to be decidable in a FINITE (but more than astronomical) number of steps. In particular, if  $n$  and  $n + 1$  are POWERS, then  $n < \exp \exp \exp 730$  (Guy 1994, p. 155), which follows from R. Tijdeman's proof that there can be only a FINITE number of exceptions should the CONJECTURE not hold.

Hyyrö and Mąkowski proved that there do not exist three consecutive POWERS (Ribenoim 1996), and it is also known that 8 and 9 are the only consecutive CUBIC and SQUARE NUMBERS (in either order).

**Catalan's Constant**

A constant which appears in estimates of combinatorial functions. It is usually denoted  $K$ ,  $\beta(2)$ , or  $G$ . It is not known if  $K$  is IRRATIONAL. Numerically,

$$K = 0.915965594177 \dots \quad (1)$$

(Sloane's A006752). The CONTINUED FRACTION for  $K$  is  $[0, 1, 10, 1, 8, 1, 88, 4, 1, 1, \dots]$  (Sloane's A014538).  $K$  can be given analytically by the following expressions,

$$K \equiv \beta(2) \quad (2)$$

$$= \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)^2} = \frac{1}{1^2} - \frac{1}{3^2} + \frac{1}{5^2} - \dots \quad (3)$$

$$= 1 + \sum_{n=1}^{\infty} \frac{1}{(4n+1)^2} - \frac{1}{9} - \sum_{n=1}^{\infty} \frac{1}{(4n+3)^2} \quad (4)$$

$$= \int_0^1 \frac{\tan^{-1} x \, dx}{x} \quad (5)$$

$$= - \int_0^1 \frac{\ln x \, dx}{1+x^2}, \quad (6)$$

where  $\beta(z)$  is the DIRICHLET BETA FUNCTION. In terms of the POLYGAMMA FUNCTION  $\Psi_1(x)$ ,

$$K = \frac{1}{16} \Psi_1\left(\frac{1}{4}\right) - \frac{1}{16} \Psi_1\left(\frac{3}{4}\right) \quad (7)$$

$$= \frac{1}{80} \Psi_1\left(\frac{5}{12}\right) + \frac{1}{80} \Psi_1\left(\frac{1}{12}\right) - \frac{1}{10} \pi^2 \quad (8)$$

$$= \frac{1}{32} \Psi_1\left(\frac{1}{8}\right) - \frac{1}{32} \Psi_1\left(\frac{3}{8}\right) - \frac{1}{16} \sqrt{2}. \quad (9)$$

Applying CONVERGENCE IMPROVEMENT to (3) gives

$$K = \frac{1}{16} \sum_{m=1}^{\infty} (m+1) \frac{3^m - 1}{4^m} \zeta(m+2), \quad (10)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION and the identity

$$\frac{1}{(1-3z)^2} - \frac{1}{(1-z)^2} = \sum_{m=1}^{\infty} (m+1) \frac{3^m - 1}{4^m} z^m \quad (11)$$

has been used (Flajolet and Vardi 1996). The Flajolet and Vardi algorithm also gives

$$K = \frac{1}{\sqrt{2}} \prod_{k=1}^{\infty} \left[ \left(1 - \frac{1}{2^{2k}}\right) \frac{\zeta(2k)}{\beta(2k)} \right]^{1/(2^{k+1})}, \quad (12)$$

where  $\beta(z)$  is the DIRICHLET BETA FUNCTION. Glaisher (1913) gave

$$K = 1 - \sum_{n=1}^{\infty} \frac{n \zeta(2n+1)}{16^n} \quad (13)$$

(Vardi 1991, p. 159). W. Gosper used the related FORMULA

$$K = \frac{1}{\sqrt{2}} \left[ \frac{1}{\Psi(2) - 1} \right]^{2^{1/2}} \prod_{k=2}^{\infty} \left[ \frac{1}{-\Psi(2^k) - 1} \right]^{1/(2^{k+1})}, \quad (14)$$

where

$$\Psi(m) = \frac{m \psi_{m-1}\left(\frac{1}{4}\right)}{\pi^m (2^m - 1) 4^{m-1} B_m}, \quad (15)$$

where  $B_n$  is a BERNOULLI NUMBER and  $\psi(x)$  is a POLY-GAMMA FUNCTION (Finch). The Catalan constant may also be defined by

$$K \equiv \frac{1}{2} \int_0^1 K(k) \, dk, \quad (16)$$

where  $K(k)$  (not to be confused with Catalan's constant itself, denoted  $K$ ) is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND.

$$K = \frac{\pi \ln 2}{8} + \sum_{i=1}^{\infty} \frac{a_i}{2^{\lfloor (i+1)/2 \rfloor} i^2}, \quad (17)$$

where

$$\{a_i\} = \{1, 1, 1, 0, -1, -1, -1, 0\} \quad (18)$$

is given by the periodic sequence obtained by appending copies of  $\{1, 1, 1, 0, -1, -1, -1, 0\}$  (in other words,  $a_i \equiv a_{[(i-1) \bmod 8] + 1}$  for  $i > 8$ ) and  $\lfloor x \rfloor$  is the FLOOR FUNCTION (Nielsen 1909).

### Catalan's Diophantine Problem

Find consecutive POWERS, i.e., solutions to

$$a^b - c^d = 1,$$

excluding 0 and 1. CATALAN'S CONJECTURE is that the only solution is  $3^2 - 2^3 = 1$ , so 8 and 9 ( $2^3$  and  $3^2$ ) are the only consecutive POWERS (again excluding 0 and 1).

see also CATALAN'S CONJECTURE

### Catalan Integrals

Special cases of general FORMULAS due to Bessel.

$$J_0(\sqrt{z^2 - y^2}) = \frac{1}{\pi} \int_0^\pi e^{y \cos \theta} \cos(z \sin \theta) d\theta,$$

where  $J_0$  is a BESSEL FUNCTION OF THE FIRST KIND. Now, let  $z \equiv 1 - z'$  and  $y \equiv 1 + z'$ . Then

$$J_0(2i\sqrt{z}) = \frac{1}{\pi} \int_0^\pi e^{(1+z) \cos \theta} \cos[(1-z) \sin \theta] d\theta.$$

### Catalan Number

The Catalan numbers are an INTEGER SEQUENCE  $\{C_n\}$  which appears in TREE enumeration problems of the type, "In how many ways can a regular  $n$ -gon be divided into  $n - 2$  TRIANGLES if different orientations are counted separately?" (EULER'S POLYGON DIVISION PROBLEM). The solution is the Catalan number  $C_{n-2}$  (Dörrie 1965, Honsberger 1973), as graphically illustrated below (Dickau).

The first few Catalan numbers are 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, ... (Sloane's A000108). The only ODD Catalan numbers are those of the form  $c_{2^k-1}$ , and the last DIGIT is five for  $k = 9$  to 15. The only PRIME Catalan numbers for  $n \leq 2^{15} - 1$  are  $C_2 = 2$  and  $C_3 = 5$ .

The Catalan numbers turn up in many other related types of problems. For instance, the Catalan number  $C_{n-1}$  gives the number of BINARY BRACKETINGS of  $n$  letters (CATALAN'S PROBLEM). The Catalan numbers also give the solution to the BALLOT PROBLEM, the number of trivalent PLANTED PLANAR TREES (Dickau),

the number of states possible in an  $n$ -FLEXAGON, the number of different diagonals possible in a FRIEZE PATTERN with  $n + 1$  rows, the number of ways of forming an  $n$ -fold exponential, the number of rooted planar binary trees with  $n$  internal nodes, the number of rooted plane bushes with  $n$  EDGES, the number of extended BINARY TREES with  $n$  internal nodes, the number of mountains which can be drawn with  $n$  upstrokes and  $n$  downstrokes, the number of noncrossing handshakes possible across a round table between  $n$  pairs of people (Conway and Guy 1996), and the number of SEQUENCES with NONNEGATIVE PARTIAL SUMS which can be formed from  $n$  1s and  $n - 1$ s (Bailey 1996, Buraldi 1992)!

An explicit formula for  $C_n$  is given by

$$C_n \equiv \frac{1}{n+1} \binom{2n}{n} = \frac{1}{n+1} \frac{(2n)!}{n!^2} = \frac{(2n)!}{(n+1)!n!}, \quad (1)$$

where  $\binom{2n}{n}$  denotes a BINOMIAL COEFFICIENT and  $n!$  is the usual FACTORIAL. A RECURRENCE RELATION for  $C_n$  is obtained from

$$\begin{aligned} \frac{C_{n+1}}{C_n} &= \frac{(2n+2)!}{(n+2)[(n+1)!]^2} \frac{(n+1)(n!)^2}{(2n)!} \\ &= \frac{(2n+2)(2n+1)(n+1)}{(n+2)(n+1)^2} \\ &= \frac{2(2n+1)(n+1)^2}{(n+1)^2(n+2)} = \frac{2(2n+1)}{n+2}, \end{aligned} \quad (2)$$

so

$$C_{n+1} = \frac{2(2n+1)}{n+2} C_n. \quad (3)$$

Other forms include

$$C_n = \frac{2 \cdot 6 \cdot 10 \cdots (4n-2)}{(n+1)!} \quad (4)$$

$$= \frac{2^n (2n-1)!!}{(n+1)!} \quad (5)$$

$$= \frac{(2n)!}{n!(n+1)!}. \quad (6)$$

SEGNER'S RECURRENCE FORMULA, given by Segner in 1758, gives the solution to EULER'S POLYGON DIVISION PROBLEM

$$E_n = E_2 E_{n-1} + E_3 E_{n-2} + \cdots + E_{n-1} E_2. \quad (7)$$

With  $E_1 = E_2 = 1$ , the above RECURRENCE RELATION gives the Catalan number  $C_{n-2} = E_n$ .

The GENERATING FUNCTION for the Catalan numbers is given by

$$\frac{1 - \sqrt{1-4x}}{2x} = \sum_{n=0}^{\infty} C_n x^n = 1 + x + 2x^2 + 5x^3 + \dots \quad (8)$$

The asymptotic form for the Catalan numbers is

$$C_k \sim \frac{4^k}{\sqrt{\pi} k^{3/2}} \quad (9)$$

(Vardi 1991, Graham *et al.* 1994).

A generalization of the Catalan numbers is defined by

$${}_p d_k = \frac{1}{k} \binom{pk}{k-1} = \frac{1}{(p-1)k+1} \binom{pk}{k} \quad (10)$$

for  $k \geq 1$  (Klarner 1970, Hilton and Pederson 1991). The usual Catalan numbers  $C_k = {}_2 d_k$  are a special case with  $p = 2$ .  ${}_p d_k$  gives the number of  $p$ -ary TREES with  $k$  source-nodes, the number of ways of associating  $k$  applications of a given  $p$ -ary OPERATOR, the number of ways of dividing a convex POLYGON into  $k$  disjoint  $(p+1)$ -gons with nonintersecting DIAGONALS, and the number of  $p$ -GOOD PATHS from  $(0, -1)$  to  $(k, (p-1)k-1)$  (Hilton and Pederson 1991).

A further generalization is obtained as follows. Let  $p$  be an INTEGER  $> 1$ , let  $P_k = (k, (p-1)k-1)$  with  $k \geq 0$ , and  $q \leq p-1$ . Then define  ${}_p d_{q0} = 1$  and let  ${}_p d_{qk}$  be the number of  $p$ -GOOD PATHS from  $(1, q-1)$  to  $P_k$  (Hilton and Pederson 1991). Formulas for  ${}_p d_{qi}$  include the generalized JONAH FORMULA

$$\binom{n-q}{k-1} = \sum_{i=1}^k {}_p d_{qi} \binom{n-pi}{k-i} \quad (11)$$

and the explicit formula

$${}_p d_{qk} = \frac{p-q}{pk-q} \binom{pk-q}{k-1}. \quad (12)$$

A RECURRENCE RELATION is given by

$${}_p d_{qk} = \sum_{i,j} {}_p d_{p-r,i} {}_p d_{q+r,j} \quad (13)$$

where  $i, j, r \geq 1$ ,  $k \geq 1$ ,  $q < p-r$ , and  $i+j = k+1$  (Hilton and Pederson 1991).

### Catalan's Problem

The problem of finding the number of different ways in which a PRODUCT of  $n$  different ordered FACTORS can be calculated by pairs (i.e., the number of BINARY BRACKETINGS of  $n$  letters). For example, for the four FACTORS  $a, b, c$ , and  $d$ , there are five possibilities:  $((ab)c)d$ ,  $(a(bc))d$ ,  $(ab)(cd)$ ,  $a((bc)d)$ , and  $a(b(cd))$ . The solution was given by Catalan in 1838 as

$$C'_n = \frac{2 \cdot 6 \cdot 10 \cdot (4n - 6)}{n!}$$

and is equal to the CATALAN NUMBER  $C_{n-1} = C'_n$ .

### Catalan Solid

The DUAL POLYHEDRA of the ARCHIMEDEAN SOLIDS, given in the following table.

Archimedean Solid	Dual
rhombicosidodecahedron	deltoidal hexecontahedron
small rhombicuboctahedron	deltoidal icositetrahedron
great rhombicuboctahedron	disdyakis dodecahedron
great rhombicosidodecahedron	disdyakis triacontahedron
truncated icosahedron	pentakis dodecahedron
snub dodecahedron	pentagonal hexecontahedron
(laevo)	(dextro)
snub cube	pentagonal icositetrahedron
(laevo)	(dextro)
cuboctahedron	rhombic dodecahedron
icosidodecahedron	rhombic triacontahedron
truncated octahedron	tetrakis hexahedron
truncated dodecahedron	triakis icosahedron
truncated cube	triakis octahedron
truncated tetrahedron	triakis tetrahedron

Here are the ARCHIMEDEAN DUALS (Holden 1971, Pearce 1978) displayed in alphabetical order (left to right, then continuing to the next row).

Here are the Archimedean solids paired with the corresponding Catalan solids.

### Catalan's Surface

A MINIMAL SURFACE given by the parametric equations

$$x(u, v) = u - \sin u \cosh v \quad (1)$$

$$y(u, v) = 1 - \cos u \cosh v \quad (2)$$

$$z(u, v) = 4 \sin\left(\frac{1}{2}u\right) \sinh\left(\frac{1}{2}v\right) \quad (3)$$

(Gray 1993), or

$$x(r, \phi) = a \sin(2\phi) - 2a\phi + \frac{1}{2}av^2 \cos(2\phi) \quad (4)$$

$$y(r, \phi) = -a \cos(2\phi) - \frac{1}{2}av^2 \cos(2\phi) \quad (5)$$

$$z(r, \phi) = 2av \sin \phi, \quad (6)$$

where

$$v = -r + \frac{1}{r} \quad (7)$$

(do Carmo 1986).

#### Catalan's Triangle

A triangle of numbers with entries given by

$$c_{nm} = \frac{(n+m)!(n-m+1)}{m!(n+1)!}$$

for  $0 \leq m \leq n$ , where each element is equal to the one above plus the one to the left. Furthermore, the sum of each row is equal to the last element of the next row and also equal to the CATALAN NUMBER  $C_n$ .

#### Catastrophe

see BUTTERFLY CATASTROPHE, CATASTROPHE THEORY, CUSP CATASTROPHE, ELLIPTIC UMBILIC CATASTROPHE, FOLD CATASTROPHE, HYPERBOLIC UMBILIC CATASTROPHE, PARABOLIC UMBILIC CATASTROPHE, SWALLOWTAIL CATASTROPHE

#### Catastrophe Theory

Catastrophe theory studies how the qualitative nature of equation solutions depends on the parameters that appear in the equations. Subspecializations include bifurcation theory, nonequilibrium thermodynamics, singularity theory, synergetics, and topological dynamics. For any system that seeks to minimize a function, only seven different local forms of catastrophe "typically" occur for four or fewer variables: (1) FOLD CATASTROPHE, (2) CUSP CATASTROPHE, (3) SWALLOWTAIL CATASTROPHE, (4) BUTTERFLY CATASTROPHE, (5) ELLIPTIC UMBILIC CATASTROPHE, (6) HYPERBOLIC UMBILIC CATASTROPHE, (7) PARABOLIC UMBILIC CATASTROPHE.

More specifically, for any system with fewer than five control factors and fewer than three behavior axes, these are the only seven catastrophes possible. The following tables gives the possible catastrophes as a function of control factors and behavior axes (Goetz).

Control Factors	1 Behavior Axis	2 Behavior Axes
1	fold	—
2	cusp	—
3	swallowtail	hyperbolic umbilic, elliptic umbilic
4	butterfly	parabolic umbilic

#### Categorical Game

A GAME in which no draw is possible.

#### Categorical Variable

A variable which belongs to exactly one of a finite number of CATEGORIES.

### Category

A category consists of two things: an OBJECT and a MORPHISM (sometimes called an "arrow"). An OBJECT is some mathematical structure (e.g., a GROUP, VECTOR SPACE, or DIFFERENTIABLE MANIFOLD) and a MORPHISM is a MAP between two OBJECTS. The MORPHISMS are then required to satisfy some fairly natural conditions; for instance, the IDENTITY MAP between any object and itself is always a MORPHISM, and the composition of two MORPHISMS (if defined) is always a MORPHISM.

One usually requires the MORPHISMS to preserve the mathematical structure of the objects. So if the objects are all groups, a good choice for a MORPHISM would be a group HOMOMORPHISM. Similarly, for vector spaces, one would choose linear maps, and for differentiable manifolds, one would choose differentiable maps.

In the category of TOPOLOGICAL SPACES, homomorphisms are usually continuous maps between topological spaces. However, there are also other category structures having TOPOLOGICAL SPACES as objects, but they are not nearly as important as the "standard" category of TOPOLOGICAL SPACES and continuous maps.

### Category Theory

The branch of mathematics which formalizes a number of algebraic properties of collections of transformations between mathematical objects (such as binary relations, groups, sets, topological spaces, etc.) of the same type, subject to the constraint that the collections contain the identity mapping and are closed with respect to compositions of mappings. The objects studied in category theory are called CATEGORIES.

see also CATEGORY

### Catenary

The curve a hanging flexible wire or chain assumes when supported at its ends and acted upon by a uniform gravitational force. The word catenary is derived from the Latin word for "chain." In 1669, Jungius disproved Galileo's claim that the curve of a chain hanging under gravity would be a PARABOLA (MacTutor Archive). The curve is also called the ALYSOID and CHAINETTE. The equation was obtained by Leibniz, Huygens, and Johann Bernoulli in 1691 in response to a challenge by Jakob Bernoulli.

Huygens was the first to use the term catenary in a letter to Leibniz in 1690, and David Gregory wrote a treatise on the catenary in 1690 (MacTutor Archive). If you roll a PARABOLA along a straight line, its FOCUS traces out a catenary. As proved by Euler in 1744, the catenary is also the curve which, when rotated, gives the surface of minimum SURFACE AREA (the CATENOID) for the given bounding CIRCLE.

The CARTESIAN equation for the catenary is given by

$$y = \frac{1}{2}a(e^{x/a} + e^{-x/a}) = a \cosh\left(\frac{x}{a}\right), \quad (1)$$

and the CESÀRO EQUATION is

$$(s^2 + a^2)\kappa = -a. \quad (2)$$

The catenary gives the shape of the road over which a regular polygonal "wheel" can travel smoothly. For a regular  $n$ -gon, the corresponding catenary is

$$y = -A \cosh\left(\frac{x}{A}\right), \quad (3)$$

where

$$A \equiv R \cos\left(\frac{\pi}{n}\right). \quad (4)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s = a \sinh\left(\frac{t}{a}\right), \quad (5)$$

$$\kappa = -\frac{1}{a} \operatorname{sech}^2\left(\frac{t}{a}\right), \quad (6)$$

$$\phi = -2 \tan^{-1}\left[\tanh\left(\frac{t}{2a}\right)\right]. \quad (7)$$

The slope is proportional to the ARC LENGTH as measured from the center of symmetry.

**Catenary Evolute**

$$x = a[x - \frac{1}{2} \sinh(2t)]$$

$$y = 2a \cosh t.$$

**Catenary Involute**

The parametric equation for a CATENARY is

$$\mathbf{r}(t) = a \begin{bmatrix} t \\ \cosh t \end{bmatrix}, \quad (1)$$

so

$$\frac{d\mathbf{r}}{dt} = a \begin{bmatrix} 1 \\ \sinh t \end{bmatrix} \quad (2)$$

$$\left| \frac{d\mathbf{r}}{dt} \right| = a\sqrt{1 + \sinh^2 t} = a \cosh t \quad (3)$$

and

$$\hat{\mathbf{T}} = \frac{\frac{d\mathbf{r}}{dt}}{\left| \frac{d\mathbf{r}}{dt} \right|} = \begin{bmatrix} \operatorname{sech} t \\ \tanh t \end{bmatrix} \quad (4)$$

$$ds^2 = |d\mathbf{r}|^2 = a^2(1 + \sinh^2 t) dt^2 = a^2 \cosh^2 t dt^2 \quad (5)$$

$$\frac{ds}{dt} = a \cosh t. \quad (6)$$

Therefore,

$$s = a \int \cosh t dt = a \sinh t \quad (7)$$

and the equation of the INVOLUTE is

$$x = a(t - \tanh t) \quad (8)$$

$$y = a \operatorname{sech} t. \quad (9)$$

This curve is called a TRACTRIX.

**Catenary Radial Curve**

The KAMPYLE OF EUDOXUS.

**Catenoid**

A CATENARY of REVOLUTION. The catenoid and PLANE are the only SURFACES OF REVOLUTION which are also MINIMAL SURFACES. The catenoid can be given by the parametric equations

$$x = c \cosh \left( \frac{v}{c} \right) \cos u \quad (1)$$

$$y = c \cosh \left( \frac{v}{c} \right) \sin u \quad (2)$$

$$z = v, \quad (3)$$

where  $u \in [0, 2\pi)$ . The differentials are

$$dx = \sinh \left( \frac{v}{c} \right) \cos u dv - \cosh \left( \frac{v}{c} \right) \sin u du \quad (4)$$

$$dy = \sinh \left( \frac{v}{c} \right) \sin u dv + \cosh \left( \frac{v}{c} \right) \cos u du \quad (5)$$

$$dz = dv, \quad (6)$$

so the LINE ELEMENT is

$$ds^2 = dx^2 + dy^2 + dz^2$$

$$= \left[ \sinh^2 \left( \frac{v}{c} \right) + 1 \right] dv^2 + \cosh^2 \left( \frac{v}{c} \right) du^2$$

$$= \cosh^2 \left( \frac{v}{c} \right) dv^2 + \cosh^2 \left( \frac{v}{c} \right) du^2. \quad (7)$$

The PRINCIPAL CURVATURES are

$$\kappa_1 = -\frac{1}{c} \operatorname{sech}^2 \left( \frac{v}{c} \right) \quad (8)$$

$$\kappa_2 = \frac{1}{c} \operatorname{sech}^2 \left( \frac{v}{c} \right). \quad (9)$$

The MEAN CURVATURE of the catenoid is

$$H = 0 \quad (10)$$

and the GAUSSIAN CURVATURE is

$$K = -\frac{1}{c^2} \operatorname{sech}^4 \left( \frac{v}{c} \right). \quad (11)$$

The HELICOID can be continuously deformed into a catenoid with  $c = 1$  by the transformation

$$x(u, v) = \cos \alpha \sinh v \sin u + \sin \alpha \cosh v \cos u \quad (12)$$

$$y(u, v) = -\cos \alpha \sinh v \cos u + \sin \alpha \cosh v \sin u \quad (13)$$

$$z(u, v) = u \cos \alpha + v \sin \alpha, \quad (14)$$

where  $\alpha = 0$  corresponds to a HELICOID and  $\alpha = \pi/2$  to a catenoid.

### Cauchy's Cosine Integral Formula

$$\int_{-\pi/2}^{\pi/2} \cos^{\mu+\nu-2} \theta e^{i\theta(\mu-\nu+2\xi)} d\theta = \frac{\pi \Gamma(\mu+\nu-1)}{2^{\mu+\nu-2} \Gamma(\mu+\xi) \Gamma(\nu-\xi)},$$

where  $\Gamma(z)$  is the GAMMA FUNCTION.

### Cauchy Criterion

A NECESSARY and SUFFICIENT condition for a SEQUENCE  $S_i$  to CONVERGE. The Cauchy criterion is satisfied when, for all  $\epsilon > 0$ , there is a fixed number  $N$  such that  $|S_j - S_i| < \epsilon$  for all  $i, j > N$ .

### Cauchy Distribution

The Cauchy distribution, also called the LORENTZIAN DISTRIBUTION, describes resonance behavior. It also describes the distribution of horizontal distances at which a LINE SEGMENT tilted at a random ANGLE cuts the  $x$ -AXIS. Let  $\theta$  represent the ANGLE that a line, with fixed point of rotation, makes with the vertical axis, as shown above. Then

$$\tan \theta = \frac{x}{b} \quad (1)$$

$$\theta = \tan^{-1} \left( \frac{x}{b} \right) \quad (2)$$

$$d\theta = -\frac{1}{1 + \frac{x^2}{b^2}} \frac{dx}{b} = -\frac{b dx}{b^2 + x^2}, \quad (3)$$

so the distribution of ANGLE  $\theta$  is given by

$$\frac{d\theta}{\pi} = -\frac{1}{\pi} \frac{b dx}{b^2 + x^2}. \quad (4)$$

This is normalized over all angles, since

$$\int_{-\pi/2}^{\pi/2} \frac{d\theta}{\pi} = 1 \quad (5)$$

and

$$\begin{aligned} -\int_{-\infty}^{\infty} \frac{1}{\pi} \frac{b dx}{b^2 + x^2} &= \frac{1}{\pi} \left[ \tan^{-1} \left( \frac{b}{x} \right) \right]_{-\infty}^{\infty} \\ &= \frac{1}{\pi} \left[ \frac{1}{2}\pi - \left(-\frac{1}{2}\pi\right) \right] = 1. \end{aligned} \quad (6)$$

The general Cauchy distribution and its cumulative distribution can be written as

$$P(x) = \frac{1}{\pi} \frac{\frac{1}{2}\Gamma}{(x - \mu)^2 + (\frac{1}{2}\Gamma)^2} \quad (7)$$

$$D(x) = \frac{1}{2} + \frac{1}{\pi} \tan^{-1} \left( \frac{x - \mu}{b} \right), \quad (8)$$

where  $\Gamma$  is the FULL WIDTH AT HALF MAXIMUM ( $\Gamma = 2b$  in the above example) and  $\mu$  is the MEAN ( $\mu = 0$  in the above example). The CHARACTERISTIC FUNCTION is

$$\begin{aligned} \phi(t) &= \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{e^{it(\Gamma x/2 - \mu)}}{1 + x^2} dx \\ &= \frac{e^{-i\mu t}}{\pi} \int_{-\infty}^{\infty} \frac{\cos(\Gamma t x/2)}{1 + (\Gamma x/2)^2} dx \\ &= e^{-i\mu t - \Gamma|t|/2}. \end{aligned} \quad (9)$$

The MOMENTS are given by

$$\mu_2 = \sigma^2 = \infty \quad (10)$$

$$\mu_3 = \begin{cases} 0 & \text{for } \mu = 0 \\ \infty & \text{for } \mu \neq 0 \end{cases} \quad (11)$$

$$\mu_4 = \infty, \quad (12)$$

and the STANDARD DEVIATION, SKEWNESS, and KURTOSIS by

$$\sigma^2 = \infty \quad (13)$$

$$\gamma_1 = \begin{cases} 0 & \text{for } \mu = 0 \\ \infty & \text{for } \mu \neq 0 \end{cases} \quad (14)$$

$$\gamma_2 = \infty. \quad (15)$$

If  $X$  and  $Y$  are variates with a NORMAL DISTRIBUTION, then  $Z \equiv X/Y$  has a Cauchy distribution with MEAN  $\mu = 0$  and full width

$$\Gamma = \frac{2\sigma_y}{\sigma_x}. \quad (16)$$

#### Cauchy Equation

see EULER EQUATION

#### Cauchy's Formula

The GEOMETRIC MEAN is smaller than the ARITHMETIC MEAN,

$$\left( \prod_{i=1}^N n_i \right)^{1/N} < \frac{\sum_{i=1}^N n_i}{N}.$$

#### Cauchy Functional Equation

The fifth of HILBERT'S PROBLEMS is a generalization of this equation.

#### Cauchy-Hadamard Theorem

The RADIUS OF CONVERGENCE of the TAYLOR SERIES

$$a_0 + a_1 z + a_2 z^2 + \dots$$

is

$$r = \frac{1}{\lim_{n \rightarrow \infty} (|a_n|)^{1/n}}.$$

see also RADIUS OF CONVERGENCE, TAYLOR SERIES

#### Cauchy Inequality

A special case of the HÖLDER SUM INEQUALITY with  $p = q = 2$ ,

$$\left( \sum_{k=1}^n a_k b_k \right)^2 \leq \left( \sum_{k=1}^n a_k^2 \right) \left( \sum_{k=1}^n b_k^2 \right), \quad (1)$$

where equality holds for  $a_k = c b_k$ . In 2-D, it becomes

$$(a^2 + b^2)(c^2 + a^2) \geq (ac + bd)^2. \quad (2)$$

It can be proven by writing

$$\sum_{i=1}^n (a_i x + b_i)^2 = \sum_{i=1}^n a_i^2 \left( x + \frac{b_i}{a_i} \right)^2 = 0. \quad (3)$$

If  $b_i/a_i$  is a constant  $c$ , then  $x = -c$ . If it is not a constant, then all terms cannot simultaneously vanish for REAL  $x$ , so the solution is COMPLEX and can be found using the QUADRATIC EQUATION

$$x = \frac{-2 \sum a_i b_i \pm \sqrt{4 \left( \sum a_i b_i \right)^2 - 4 \sum a_i^2 \sum b_i^2}}{2 \sum a_i^2}. \quad (4)$$

In order for this to be COMPLEX, it must be true that

$$\left(\sum_i a_i b_i\right)^2 \leq \left(\sum_i a_i^2\right) \left(\sum_i b_i^2\right), \quad (5)$$

with equality when  $b_i/a_i$  is a constant. The VECTOR derivation is much simpler,

$$(\mathbf{a} \cdot \mathbf{b})^2 = a^2 b^2 \cos^2 \theta \leq a^2 b^2, \quad (6)$$

where

$$a^2 \equiv \mathbf{a} \cdot \mathbf{a} = \sum_i a_i^2, \quad (7)$$

and similarly for  $b$ .

see also CHERYSHEV INEQUALITY, HÖLDER SUM INEQUALITY

### Cauchy Integral Formula

Given a CONTOUR INTEGRAL of the form

$$\int_{\gamma} \frac{f(z) dz}{z - z_0}, \quad (1)$$

define a path  $\gamma_0$  as an infinitesimal CIRCLE around the point  $z_0$  (the dot in the above illustration). Define the path  $\gamma_r$  as an arbitrary loop with a cut line (on which the forward and reverse contributions cancel each other out) so as to go around  $z_0$ .

The total path is then

$$\gamma = \gamma_0 + \gamma_r, \quad (2)$$

so

$$\int_{\gamma} \frac{f(z) dz}{z - z_0} = \int_{\gamma_0} \frac{f(z) dz}{z - z_0} + \int_{\gamma_r} \frac{f(z) dz}{z - z_0}. \quad (3)$$

From the CAUCHY INTEGRAL THEOREM, the CONTOUR INTEGRAL along any path not enclosing a POLE is 0. Therefore, the first term in the above equation is 0 since  $\gamma_0$  does not enclose the POLE, and we are left with

$$\int_{\gamma} \frac{f(z) dz}{z - z_0} = \int_{\gamma_r} \frac{f(z) dz}{z - z_0}. \quad (4)$$

Now, let  $z = z_0 + re^{i\theta}$ , so  $dz = ire^{i\theta} d\theta$ . Then

$$\begin{aligned} \int_{\gamma} \frac{f(z) dz}{z - z_0} &= \int_{\gamma_r} \frac{f(z_0 + re^{i\theta})}{re^{i\theta}} ire^{i\theta} d\theta \\ &= \int_{\gamma_r} f(z_0 + re^{i\theta}) i d\theta. \end{aligned} \quad (5)$$

But we are free to allow the radius  $r$  to shrink to 0, so

$$\begin{aligned} \int_{\gamma} \frac{f(z) dz}{z - z_0} &= \lim_{r \rightarrow 0} \int_{\gamma_r} f(z_0 + re^{i\theta}) i d\theta = \int_{\gamma_r} f(z_0) i d\theta \\ &= if(z_0) \int_{\gamma_r} d\theta = 2\pi i f(z_0), \end{aligned} \quad (6)$$

and

$$f(z_0) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(z) dz}{z - z_0}. \quad (7)$$

If multiple loops are made around the POLE, then equation (7) becomes

$$n(\gamma, z_0) f(z_0) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(z) dz}{z - z_0}, \quad (8)$$

where  $n(\gamma, z_0)$  is the WINDING NUMBER.

A similar formula holds for the derivatives of  $f(z)$ ,

$$\begin{aligned} f'(z_0) &= \lim_{h \rightarrow 0} \frac{f(z_0 + h) - f(z_0)}{h} \\ &= \lim_{h \rightarrow 0} \frac{1}{2\pi i h} \left( \int_{\gamma} \frac{f(z) dz}{z - z_0 - h} - \int_{\gamma} \frac{f(z) dz}{z - z_0} \right) \\ &= \lim_{h \rightarrow 0} \frac{1}{2\pi i h} \int_{\gamma} \frac{f(z)[(z - z_0) - (z - z_0 - h)] dz}{(z - z_0 - h)(z - z_0)} \\ &= \lim_{h \rightarrow 0} \frac{1}{2\pi i h} \int_{\gamma} \frac{hf(z) dz}{(z - z_0 - h)(z - z_0)} \\ &= \frac{1}{2\pi i} \int_{\gamma} \frac{f(z) dz}{(z - z_0)^2}. \end{aligned} \quad (9)$$

Iterating again,

$$f''(z_0) = \frac{2}{2\pi i} \int_{\gamma} \frac{f(z) dz}{(z - z_0)^3}. \quad (10)$$

Continuing the process and adding the WINDING NUMBER  $n$ ,

$$n(\gamma, z_0) f^{(r)}(z_0) = \frac{r!}{2\pi i} \int_{\gamma} \frac{f(z) dz}{(z - z_0)^{r+1}}. \quad (11)$$

see also MORERA'S THEOREM

### References

**Cauchy Integral Test**

see INTEGRAL TEST

**Cauchy Integral Theorem**

If  $f$  is continuous and finite on a simply connected region  $R$  and has only finitely many points of nondifferentiability in  $R$ , then

$$\oint_{\gamma} f(z) dz = 0 \quad (1)$$

for any closed CONTOUR  $\gamma$  completely contained in  $R$ . Writing  $z$  as

$$z \equiv x + iy \quad (2)$$

and  $f(z)$  as

$$f(z) \equiv u + iv \quad (3)$$

then gives

$$\begin{aligned} \oint_{\gamma} f(z) dz &= \int_{\gamma} (u + iv)(dx + i dy) \\ &= \int_{\gamma} u dx - v dy + i \int_{\gamma} v dx + u dy. \end{aligned} \quad (4)$$

From GREEN'S THEOREM,

$$\int_{\gamma} f(x, y) dx - g(x, y) dy = - \iint \left( \frac{\partial g}{\partial x} + \frac{\partial f}{\partial y} \right) dx dy, \quad (5)$$

$$\int_{\gamma} f(x, y) dx + g(x, y) dy = \iint \left( \frac{\partial g}{\partial x} - \frac{\partial f}{\partial y} \right) dx dy \quad (6)$$

so (4) becomes

$$\begin{aligned} \oint_{\gamma} f(z) dz &= - \iint \left( \frac{\partial v}{\partial x} + \frac{\partial u}{\partial y} \right) dx dy \\ &\quad + i \iint \left( \frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right) dx dy. \end{aligned} \quad (7)$$

But the CAUCHY-RIEMANN EQUATIONS require that

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad (8)$$

$$\frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}, \quad (9)$$

so

$$\oint_{\gamma} f(z) dz = 0, \quad (10)$$

Q. E. D.

For a MULTIPLY CONNECTED region,

$$\int_{C_1} f(z) dz = \int_{C_2} f(z) dz. \quad (11)$$

**Cauchy Problem**

If  $f(x, y)$  is an ANALYTIC FUNCTION in a NEIGHBORHOOD of the point  $(x_0, y_0)$  (i.e., it can be expanded in a series of NONNEGATIVE INTEGER POWERS of  $(x - x_0)$  and  $(y - y_0)$ ), find a solution  $y(x)$  of the DIFFERENTIAL EQUATION

$$\frac{dy}{dx} = f(x),$$

with initial conditions  $y = y_0$  and  $x = x_0$ . The existence and uniqueness of the solution were proven by Cauchy and Kovalevskaya in the CAUCHY-KOVALEVSKAYA THEOREM. The Cauchy problem amounts to determining the shape of the boundary and type of equation which yield unique and reasonable solutions for the CAUCHY BOUNDARY CONDITIONS.

see also CAUCHY BOUNDARY CONDITIONS

**Cauchy Ratio Test**

see RATIO TEST

**Cauchy Remainder Form**

The remainder of  $n$  terms of a TAYLOR SERIES is given by

$$R_n = \frac{(x-c)^{n-1}(x-a)}{(n-1)!} f^{(n)}(c),$$

where  $a \leq c \leq x$ .

**Cauchy-Riemann Equations**

Let

$$f(x, y) = u(x, y) + iv(x, y), \quad (1)$$

where

$$z \equiv x + iy, \quad (2)$$

so

$$dz = dx + i dy. \quad (3)$$

The total derivative of  $f$  with respect to  $z$  may then be computed as follows.

$$y = \frac{z-x}{i} \quad (4)$$

$$x = z - iy, \quad (5)$$

so

$$\frac{\partial y}{\partial z} = \frac{1}{i} = -i \quad (6)$$

$$\frac{\partial x}{\partial z} = 1, \quad (7)$$

and

$$\frac{df}{dz} = \frac{\partial f}{\partial x} \frac{\partial x}{\partial z} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial z} = \frac{\partial f}{\partial x} - i \frac{\partial f}{\partial y}. \quad (8)$$

In terms of  $u$  and  $v$ , (8) becomes

$$\begin{aligned} \frac{df}{dz} &= \left( \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \right) - i \left( \frac{\partial u}{\partial y} + i \frac{\partial v}{\partial y} \right) \\ &= \left( \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \right) + \left( -i \frac{\partial u}{\partial y} + \frac{\partial v}{\partial y} \right). \end{aligned} \quad (9)$$

Along the real, or  $x$ -AXIS,  $\partial f / \partial y = 0$ , so

$$\frac{df}{dz} = \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x}. \quad (10)$$

Along the imaginary, or  $y$ -axis,  $\partial f / \partial x = 0$ , so

$$\frac{df}{dz} = -i \frac{\partial u}{\partial y} + \frac{\partial v}{\partial y}. \quad (11)$$

If  $f$  is COMPLEX DIFFERENTIABLE, then the value of the derivative must be the same for a given  $dz$ , regardless of its orientation. Therefore, (10) must equal (11), which requires that

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad (12)$$

and

$$\frac{\partial v}{\partial x} = -\frac{\partial u}{\partial y}. \quad (13)$$

These are known as the Cauchy-Riemann equations. They lead to the condition

$$\frac{\partial^2 u}{\partial x \partial y} = -\frac{\partial^2 v}{\partial x \partial y}. \quad (14)$$

The Cauchy-Riemann equations may be concisely written as

$$\begin{aligned} \frac{df}{dz^*} &= \frac{\partial f}{\partial x} + i \frac{\partial f}{\partial y} = \left( \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \right) + i \left( \frac{\partial u}{\partial y} + i \frac{\partial v}{\partial y} \right) \\ &= \left( \frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right) + i \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right) = 0. \end{aligned} \quad (15)$$

In POLAR COORDINATES,

$$f(re^{i\theta}) \equiv R(r, \theta)e^{i\Theta(r, \theta)}, \quad (16)$$

so the Cauchy-Riemann equations become

$$\frac{\partial R}{\partial r} = \frac{R}{r} \frac{\partial \Theta}{\partial \theta} \quad (17)$$

$$\frac{1}{r} \frac{\partial R}{\partial \theta} = -R \frac{\partial \Theta}{\partial r}. \quad (18)$$

If  $u$  and  $v$  satisfy the Cauchy-Riemann equations, they also satisfy LAPLACE'S EQUATION in 2-D, since

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = \frac{\partial}{\partial x} \left( \frac{\partial v}{\partial y} \right) + \frac{\partial}{\partial y} \left( -\frac{\partial v}{\partial x} \right) = 0 \quad (19)$$

$$\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} = \frac{\partial}{\partial x} \left( -\frac{\partial u}{\partial y} \right) + \frac{\partial}{\partial y} \left( \frac{\partial u}{\partial x} \right) = 0. \quad (20)$$

By picking an arbitrary  $f(z)$ , solutions can be found which automatically satisfy the Cauchy-Riemann equations and LAPLACE'S EQUATION. This fact is used to find so-called CONFORMAL SOLUTIONS to physical problems involving scalar potentials such as fluid flow and electrostatics.

**Cayley-Bacharach Theorem**

Let  $X_1, X_2 \subset \mathbb{P}^2$  be CUBIC plane curves meeting in nine points  $p_1, \dots, p_9$ . If  $X \subset \mathbb{P}^2$  is any CUBIC containing  $p_1, \dots, p_8$ , then  $X$  contains  $p_9$  as well. It is related to GORENSTEIN RINGS, and is a generalization of PAPPUS'S HEXAGON THEOREM and PASCAL'S THEOREM.

References

Eisenbud, D.; Green, M.; and Harris, J. "Cayley-Bacharach Theorems and Conjectures." *Bull. Amer. Math. Soc.* **33**, 295–324, 1996.

**Cayley Cubic**

A CUBIC RULED SURFACE (Fischer 1986) in which the director line meets the director CONIC SECTION. Cayley's surface is the unique cubic surface having four ORDINARY DOUBLE POINTS (Hunt), the maximum possible for CUBIC SURFACE (Endraß). The Cayley cubic is invariant under the TETRAHEDRAL GROUP and contains exactly nine lines, six of which connect the four nodes pairwise and the other three of which are coplanar (Endraß).

If the ORDINARY DOUBLE POINTS in projective 3-space are taken as  $(1, 0, 0, 0)$ ,  $(0, 1, 0, 0)$ ,  $(0, 0, 1, 0)$ ,  $(0, 0, 0, 1)$ , then the equation of the surface in projective coordinates is

$$\frac{1}{x_0} + \frac{1}{x_1} + \frac{1}{x_2} + \frac{1}{x_3} = 0$$

(Hunt). Defining “affine” coordinates with plane at infinity  $v = x_0 + x_1 + x_2 + 2x_3$  and

$$\begin{aligned}x &= \frac{x_0}{v} \\y &= \frac{x_1}{v} \\z &= \frac{x_2}{v}\end{aligned}$$

then gives the equation

$$-5(x^2y + x^2z + y^2x + y^2z + z^2y + z^2x) + 2(xy + xz + yz) = 0$$

plotted in the left figure above (Hunt). The slightly different form

$$4(x^3 + y^3 + z^3 + w^3) - (x + y + z + w)^3 = 0$$

is given by Endraß which, when rewritten in TETRAHEDRAL COORDINATES, becomes

$$x^2 + y^2 - x^2z + y^2z + z^2 - 1 = 0,$$

plotted in the right figure above.

The Hessian of the Cayley cubic is given by

$$\begin{aligned}0 &= x_0^2(x_1x_2 + x_1x_3 + x_2x_3) + x_1^2(x_0x_2 + x_0x_3 + x_2x_3) \\ &\quad + x_2^2(x_0x_1 + x_0x_3 + x_1x_3) + x_3^2(x_0x_1 + x_0x_2 + x_1x_2).\end{aligned}$$

in homogeneous coordinates  $x_0, x_1, x_2$ , and  $x_3$ . Taking the plane at infinity as  $v = 5(x_0 + x_1 + x_2 + 2x_3)/2$  and setting  $x, y$ , and  $z$  as above gives the equation

$$\begin{aligned}25[x^3(y+z) + y^3(x+z) + z^3(x+y)] + 50(x^2y^2 + x^2z^2 + y^2z^2) \\ - 125(x^2yz + y^2xz + z^2xy) + 60xyz - 4(xy + xz + yz) = 0,\end{aligned}$$

plotted above (Hunt). The Hessian of the Cayley cubic has 14 ORDINARY DOUBLE POINTS, four more than a the general Hessian of a smooth CUBIC SURFACE (Hunt).

### Cayley-Hamilton Theorem

Given

$$\begin{vmatrix} a_{11} - x & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} - x & \cdots & a_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mm} - x \end{vmatrix} = x^m + c_{m-1}x^{m-1} + \cdots + c_0, \quad (1)$$

then

$$A^m + c_{m-1}A^{m-1} + \cdots + c_0I = 0, \quad (2)$$

where  $I$  is the IDENTITY MATRIX. Cayley verified this identity for  $m = 2$  and 3 and postulated that it was true for all  $m$ . For  $m = 2$ , direct verification gives

$$\begin{vmatrix} a - x & b \\ c & d - x \end{vmatrix} = (a - x)(d - x) - bc = x^2 - (a + d)x + (ad - bc) \equiv x^2 + c_1x + c_2 \quad (3)$$

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \quad (4)$$

$$A^2 = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} a^2 + bc & ab + bd \\ ac + cd & bc + d^2 \end{bmatrix} \quad (5)$$

$$-(a+d)A = \begin{bmatrix} -a^2 - ad & -ab - bd \\ -ac - dc & -ad - d^2 \end{bmatrix} \quad (6)$$

$$(ad - bc)I = \begin{bmatrix} ad - bc & 0 \\ 0 & ad - bc \end{bmatrix}, \quad (7)$$

so

$$A^2 - (a+d)A + (ad - bc)I = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}. \quad (8)$$

The Cayley-Hamilton theorem states that a  $n \times n$  MATRIX  $A$  is annihilated by its CHARACTERISTIC POLYNOMIAL  $\det(xI - A)$ , which is monic of degree  $n$ .

#### Cayley's Hypergeometric Function Theorem

If

$$(1 - z)^{a+b-c} {}_2F_1(2a, 2b; 2c; z) = \sum_{n=0}^{\infty} a_n z^n,$$

then

$${}_2F_1(a, b; c + \tfrac{1}{2}; z) {}_2F_1(c - a, c - b; c; \tfrac{1}{2}z) = \sum_{n=0}^{\infty} \frac{(c)_n}{(c + \tfrac{1}{2})^n} a_n z^n,$$

where  ${}_2F_1(a, b; c; z)$  is a HYPERGEOMETRIC FUNCTION. see also HYPERGEOMETRIC FUNCTION

#### Cayley-Klein Parameters

The parameters  $\alpha$ ,  $\beta$ ,  $\gamma$ , and  $\delta$  which, like the three EULER ANGLES, provide a way to uniquely characterize the orientation of a solid body. These parameters satisfy the identities

$$\alpha\alpha^* + \gamma\gamma^* = 1 \quad (1)$$

$$\alpha\alpha^* + \beta\beta^* = 1 \quad (2)$$

$$\beta\beta^* + \delta\delta^* = 1 \quad (3)$$

$$\alpha^*\beta + \gamma^*\delta = 0 \quad (4)$$

$$\alpha\delta - \beta\gamma = 1 \quad (5)$$

and

$$\beta = -\gamma^* \quad (6)$$

$$\delta = \alpha^*, \quad (7)$$

where  $z^*$  denotes the COMPLEX CONJUGATE. In terms of the EULER ANGLES  $\theta$ ,  $\phi$ , and  $\psi$ , the Cayley-Klein parameters are given by

$$\alpha = e^{i(\psi+\phi)/2} \cos(\tfrac{1}{2}\theta) \quad (8)$$

$$\beta = ie^{i(\psi-\phi)/2} \sin(\tfrac{1}{2}\theta) \quad (9)$$

$$\gamma = ie^{-i(\psi-\phi)/2} \sin(\tfrac{1}{2}\theta) \quad (10)$$

$$\delta = e^{-(\psi+\phi)/2} \cos(\tfrac{1}{2}\theta) \quad (11)$$

(Goldstein 1960, p. 155).

The transformation matrix is given in terms of the Cayley-Klein parameters by

$$A = \begin{bmatrix} \tfrac{1}{2}(\alpha^2 - \gamma^2 + \delta^2 - \beta^2) & \tfrac{1}{2}i(\gamma^2 - \alpha^2 + \delta^2 - \beta^2) & \gamma\delta - \alpha\beta \\ \tfrac{1}{2}i(\alpha^2 + \gamma^2 - \beta^2 - \delta^2) & \tfrac{1}{2}(\alpha^2 + \gamma^2 + \beta^2 + \delta^2) & -i(\alpha\beta + \gamma\delta) \\ \beta\delta - \alpha\gamma & i(\alpha\gamma + \beta\delta) & \alpha\delta + \beta\gamma \end{bmatrix} \quad (12)$$

(Goldstein 1960, p. 153).

The Cayley-Klein parameters may be viewed as parameters of a matrix (denoted  $Q$  for its close relationship with QUATERNIONS)

$$Q = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \quad (13)$$

which characterizes the transformations

$$u' = \alpha u + \beta v \quad (14)$$

$$v' = \gamma u + \delta v. \quad (15)$$

of a linear space having complex axes. This matrix satisfies

$$Q^\dagger Q = QQ^\dagger = I, \quad (16)$$

where  $I$  is the IDENTITY MATRIX and  $A^\dagger$  the MATRIX TRANSPOSE, as well as

$$|Q|^*|Q| = 1. \quad (17)$$

In terms of the EULER PARAMETERS  $e_i$  and the PAULI MATRICES  $\sigma_i$ , the  $Q$ -matrix can be written as

$$Q = e_0 I + i(e_1 \sigma_1 + e_2 \sigma_2 + e_3 \sigma_3) \quad (18)$$

(Goldstein 1980, p. 156).

**Cayley-Klein-Hilbert Metric**

The METRIC of Felix Klein's model for HYPERBOLIC GEOMETRY,

$$g_{11} = \frac{a^2(1 - x_2^2)}{(1 - x_1^2 - x_2^2)^2}$$

$$g_{12} = \frac{a^2 x_1 x_2}{(1 - x_1^2 - x_2^2)^2}$$

$$g_{22} = \frac{a^2(1 - x_1^2)}{(1 - x_1^2 - x_2^2)^2}.$$

see also HYPERBOLIC GEOMETRY

**Cayley Number**

There are two completely different definitions of Cayley numbers. The first type Cayley numbers is one of the eight elements in a CAYLEY ALGEBRA, also known as an OCTONION. A typical Cayley number is of the form

$$a + bi_0 + ci_1 + di_2 + ei_3 + fi_4 + gi_5 + hi_6,$$

where each of the triples  $(i_0, i_1, i_3)$ ,  $(i_1, i_2, i_4)$ ,  $(i_2, i_3, i_5)$ ,  $(i_3, i_4, i_6)$ ,  $(i_4, i_5, i_0)$ ,  $(i_5, i_6, i_1)$ ,  $(i_6, i_0, i_2)$  behaves like the QUATERNIONS  $(i, j, k)$ . Cayley numbers are *not* ASSOCIATIVE. They have been used in the study of 7- and 8-D space, and a general rotation in 8-D space can be written

$$x' \rightarrow ((((((x_{c1})c_2)c_3)c_4)c_5)c_6)c_7).$$

The second type of Cayley number is a quantity which describes a DEL PEZZO SURFACE.

see also COMPLEX NUMBER, DEL PEZZO SURFACE, QUATERNION, REAL NUMBER

**Cayley's Ruled Surface**

see CAYLEY CUBIC

**Cayley's Sextic**

A plane curve discovered by Maclaurin but first studied in detail by Cayley. The name Cayley's sextic is due to R. C. Archibald, who attempted to classify curves in a paper published in Strasbourg in 1900 (MacTutor Archive). Cayley's sextic is given in POLAR COORDINATES by

$$r = a \cos^3\left(\frac{1}{3}\theta\right), \quad (1)$$

or

$$r = 4b \cos^3\left(\frac{1}{3}\theta\right), \quad (2)$$

where  $b \equiv a/4$ . In the latter case, the CARTESIAN equation is

$$4(x^2 + y^2 - bx)^3 = 27a^2(x^2 + y^2)^2. \quad (3)$$

The parametric equations are

$$x(t) = 4a \cos^4\left(\frac{1}{2}t\right)(2 \cos t - 1) \quad (4)$$

$$y(t) = 4a \cos^3\left(\frac{1}{2}t\right) \sin\left(\frac{3}{2}t\right). \quad (5)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = 3(t + \sin t), \quad (6)$$

$$\kappa(t) = \frac{1}{3} \sec^2\left(\frac{1}{2}t\right), \quad (7)$$

$$\phi(t) = 2t. \quad (8)$$

### Cell

A finite regular POLYTOPE.

see also 16-CELL, 24-CELL, 120-CELL, 600-CELL

### Cellular Automaton

A grid (possibly 1-D) of cells which evolves according to a set of rules based on the states of surrounding cells. von Neumann was one of the first people to consider such a model, and incorporated a cellular model into his "universal constructor." von Neumann proved that an automaton consisting of cells with four orthogonal neighbors and 29 possible states would be capable of simulating a TURING MACHINE for some configuration of about 200,000 cells (Gardner 1983, p. 227).

1-D automata are called "elementary" and are represented by a row of pixels with states either 0 or 1. These can be represented with an 8-bit binary number, as shown by Stephen Wolfram. Wolfram further restricted the number from  $2^8 = 256$  to 32 by requiring certain symmetry conditions.

The most well-known cellular automaton is Conway's game of LIFE, popularized in Martin Gardner's *Scientific American* columns. Although the computation of successive LIFE generations was originally done by hand, the computer revolution soon arrived and allowed more extensive patterns to be studied and propagated.

## Cellular Space

A HAUSDORFF SPACE which has the structure of a so-called CW-COMPLEX.

## Center

A special POINT which usually has some symmetric placement with respect to points on a curve or in a SOLID. The center of a CIRCLE is equidistant from all points on the CIRCLE and is the intersection of any two distinct DIAMETERS. The same holds true for the center of a SPHERE.

see also CENTER (GROUP), CENTER OF MASS, CIRCUMCENTER, CURVATURE CENTER, ELLIPSE, EQUIBROCARD CENTER, EXCENTER, HOMOTHETIC CENTER, INCENTER, INVERSION CENTER, ISOGONIC CENTERS, MAJOR TRIANGLE CENTER, NINE-POINT CENTER, ORTHOCENTER, PERSPECTIVE CENTER, POINT, RADICAL CENTER, SIMILITUDE CENTER, SPHERE, SPIEKER CENTER, TAYLOR CENTER, TRIANGLE CENTER, TRIANGLE CENTER FUNCTION, YFF CENTER OF CONGRUENCE

## Center Function

see TRIANGLE CENTER FUNCTION

## Center of Gravity

see CENTER OF MASS

## Center (Group)

The center of a GROUP is the set of elements which commute with every member of the GROUP. It is equal to the intersection of the CENTRALIZERS of the GROUP elements.

see also ISOCLINIC GROUPS, NILPOTENT GROUP

## Center of Mass

see CENTROID (GEOMETRIC)

## Centered Cube Number

A FIGURATE NUMBER of the form,

$$CCub_n = n^3 + (n-1)^3 = (2n-1)(n^2 - n + 1).$$

The first few are 1, 9, 35, 91, 189, 341, ... (Sloane's A005898). The GENERATING FUNCTION for the centered cube numbers is

$$\frac{x(x^3 + 5x^2 + 5x + 1)}{(x-1)^4} = x + 9x^2 + 35x^3 + 91x^4 + \dots$$

see also CUBIC NUMBER

Sloane, N. J. A. Sequence A005898/M4616 in "An On-Line Version of the Encyclopedia of Integer Sequences."

## Centered Hexagonal Number

see HEX NUMBER

## Centered Pentagonal Number

A CENTERED POLYGONAL NUMBER consisting of a central dot with five dots around it, and then additional dots in the gaps between adjacent dots. The general term is  $(5n^2 - 5n + 2)/2$ , and the first few such numbers are 1, 6, 16, 31, 51, 76, ... (Sloane's A005891). The GENERATING FUNCTION of the centered pentagonal numbers is

$$\frac{x(x^2 + 3x + 1)}{(x-1)^3} = x + 6x^2 + 16x^3 + 31x^4 + \dots$$

see also CENTERED SQUARE NUMBER, CENTERED TRIANGULAR NUMBER

## References

Sloane, N. J. A. Sequence A005891/M4112 in "An On-Line Version of the Encyclopedia of Integer Sequences."

## Centered Polygonal Number

A FIGURATE NUMBER in which layers of POLYGONS are drawn centered about a point instead of with the point at a VERTEX.

see also CENTERED PENTAGONAL NUMBER, CENTERED SQUARE NUMBER, CENTERED TRIANGULAR NUMBER

## References

Sloane, N. J. A. and Plouffe, S. Extended entry for sequence M3826 in *The Encyclopedia of Integer Sequences*. San Diego, CA: Academic Press, 1995.

## Centered Square Number

A CENTERED POLYGONAL NUMBER consisting of a central dot with four dots around it, and then additional dots in the gaps between adjacent dots. The general term is  $n^2 + (n-1)^2$ , and the first few such numbers are 1, 5, 13, 25, 41, ... (Sloane's A001844). Centered square numbers are the sum of two consecutive SQUARE NUMBERS and are congruent to 1 (mod 4). The GENERATING FUNCTION giving the centered square numbers is

$$\frac{x(x+1)^2}{(1-x)^3} = x + 5x^2 + 13x^3 + 25x^4 + \dots$$

see also CENTERED PENTAGONAL NUMBER, CENTERED POLYGONAL NUMBER, CENTERED TRIANGULAR NUMBER, SQUARE NUMBER

## References

Sloane, N. J. A. Sequence A001844/M3826 in "An On-Line Version of the Encyclopedia of Integer Sequences."

## Centered Triangular Number

A CENTERED POLYGONAL NUMBER consisting of a central dot with three dots around it, and then additional

dots in the gaps between adjacent dots. The general term is  $(3n^2 - 3n + 2)/2$ , and the first few such numbers are 1, 4, 10, 19, 31, 46, 64, ... (Sloane's A005448). The GENERATING FUNCTION giving the centered triangular numbers is

$$\frac{x(x^2 + x + 1)}{(1-x)^3} = x + 4x^2 + 10x^3 + 19x^4 + \dots$$

see also CENTERED PENTAGONAL NUMBER, CENTERED SQUARE NUMBER

## Centillion

In the American system,  $10^{303}$ .

see also LARGE NUMBER

## Central Angle

An ANGLE having its VERTEX at a CIRCLE's center which is formed by two points on the CIRCLE's CIRCUMFERENCE. For angles with the same endpoints,

$$\theta_c = 2\theta_i,$$

where  $\theta_i$  is the INSCRIBED ANGLE.

## References

Pedoe, D. *Circles: A Mathematical View*, rev. ed. Washington, DC: Math. Assoc. Amer., pp. xxi-xxii, 1995.

## Central Beta Function

The central beta function is defined by

$$\beta(p) \equiv B(p, p), \quad (1)$$

where  $B(p, q)$  is the BETA FUNCTION. It satisfies the identities

$$\beta(p) = 2^{1-2p} B(p, \tfrac{1}{2}) \quad (2)$$

$$= 2^{1-2p} \cos(\pi p) B(\tfrac{1}{2} - p, p) \quad (3)$$

$$= \int_0^1 \frac{t^p dt}{(1+t)^{2p}} \quad (4)$$

$$= \frac{2}{p} \prod_{n=1}^{\infty} \frac{n(n+2p)}{(n+p)(n+p)} \quad (5)$$

With  $p = 1/2$ , the latter gives the WALLIS FORMULA. When  $p = a/b$ ,

$$b\beta(a/b) = 2^{1-2a/b} J(a, b), \quad (6)$$

where

$$J(a, b) \equiv \int_0^1 \frac{t^{a-1} dt}{\sqrt{1-t^b}}. \quad (7)$$

The central beta function satisfies

$$(2+4x)\beta(1+x) = x\beta(x) \quad (8)$$

$$(1-2x)\beta(1-x)\beta(x) = 2\pi \cot(\pi x) \quad (9)$$

$$\beta(\tfrac{1}{2} - x) = 2^{4x-1} \tan(\pi x) \beta(x) \quad (10)$$

$$\beta(x)\beta(x + \tfrac{1}{2}) = 2^{4x+1} \pi \beta(2x)\beta(2x + \tfrac{1}{2}). \quad (11)$$

For  $p$  an ODD POSITIVE INTEGER, the central beta function satisfies the identity

$$\beta(px) = \frac{1}{\sqrt{p}} \prod_{k=1}^{(p-1)/2} \frac{2x + \frac{2k-1}{p}}{2\pi} \prod_{k=0}^{p-1} \beta\left(x + \frac{k}{p}\right). \quad (12)$$

#### Central Binomial Coefficient

The  $n$ th central binomial coefficient is defined as  $\binom{n}{\lfloor n/2 \rfloor}$ , where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT and  $\lfloor n \rfloor$  is the FLOOR FUNCTION. The first few values are 1, 2, 3, 6, 10, 20, 35, 70, 126, 252, ... (Sloane's A001405). The central binomial coefficients have GENERATING FUNCTION

$$\frac{1 - 4x^2 - \sqrt{1 - 4x^2}}{2(2x^3 - x^2)} = 1 + 2x + 3x^2 + 6x^3 + 10x^4 + \dots$$

The central binomial coefficients are SQUAREFREE only for  $n = 1, 2, 3, 4, 5, 7, 8, 11, 17, 19, 23, 71, \dots$  (Sloane's A046098), with no others less than 1500.

The above coefficients are a superset of the alternative "central" binomial coefficients

$$\binom{2n}{n} = \frac{(2n)!}{(n!)^2},$$

which have GENERATING FUNCTION

$$\frac{1}{\sqrt{1-4x}} = 1 + 2x + 6x^2 + 20x^3 + 70x^4 + \dots$$

The first few values are 2, 6, 20, 70, 252, 924, 3432, 12870, 48620, 184756, ... (Sloane's A000984).

Erdős and Graham (1980, p. 71) conjectured that the central binomial coefficient  $\binom{2n}{n}$  is *never* SQUAREFREE for  $n > 4$ , and this is sometimes known as the ERDŐS SQUAREFREE CONJECTURE. SÁRKÖZY'S THEOREM (Sárközy 1985) provides a partial solution which states that the BINOMIAL COEFFICIENT  $\binom{2n}{n}$  is never SQUAREFREE for all sufficiently large  $n \geq n_0$  (Vardi 1991). Granville and Ramare (1996) proved that the *only* SQUAREFREE values are  $n = 2$  and 4. Sander (1992) subsequently showed that  $\binom{2n \pm d}{n}$  are also never SQUAREFREE for sufficiently large  $n$  as long as  $d$  is not "too big."

**Central Difference**

The central difference for a function tabulated at equal intervals  $f_i$  is defined by

$$\delta(f_{n+1/2}) = \delta_{n+1/2} = \delta_{n+1/2}^1 \equiv f_{n+1} - f_n. \quad (1)$$

Higher order differences may be computed for EVEN and ODD powers,

$$\delta_{n+1/2}^{2k} = \sum_{j=0}^{2k} (-1)^j \binom{2k}{j} f_{n+k-j} \quad (2)$$

$$\delta_{n+1/2}^{2k+1} = \sum_{j=0}^{2k+1} (-1)^j \binom{2k+1}{j} f_{n+k+1-j}. \quad (3)$$

**Central Limit Theorem**

Let  $x_1, x_2, \dots, x_N$  be a set of  $N$  INDEPENDENT random variates and each  $x_i$  have an *arbitrary* probability distribution  $P(x_1, \dots, x_N)$  with MEAN  $\mu_i$  and a finite VARIANCE  $\sigma_i^2$ . Then the normal form variate

$$X_{\text{norm}} \equiv \frac{\sum_{i=1}^N x_i - \sum_{i=1}^N \mu_i}{\sqrt{\sum_{i=1}^N \sigma_i^2}} \quad (1)$$

has a limiting distribution which is NORMAL (GAUSSIAN) with MEAN  $\mu = 0$  and VARIANCE  $\sigma^2 = 1$ . If conversion to normal form is not performed, then the variate

$$X \equiv \frac{1}{N} \sum_{i=1}^N x_i \quad (2)$$

is NORMALLY DISTRIBUTED with  $\mu_X = \mu_x$  and  $\sigma_X = \sigma_x/\sqrt{N}$ . To prove this, consider the INVERSE FOURIER TRANSFORM of  $P_X(f)$ .

$$\begin{aligned} \mathcal{F}^{-1}[P_X(f)] &\equiv \int_{-\infty}^{\infty} e^{2\pi i f X} p(X) dX \\ &= \int_{-\infty}^{\infty} \sum_{n=0}^{\infty} \frac{(2\pi i f X)^n}{n!} p(X) dX \\ &= \sum_{n=0}^{\infty} \frac{(2\pi i f)^n}{n!} \int_{-\infty}^{\infty} X^n p(X) dX \\ &= \sum_{n=0}^{\infty} \frac{(2\pi i f)^n}{n!} \langle x \rangle^n. \end{aligned} \quad (3)$$

Now write

$$\begin{aligned} \langle X^n \rangle &= \langle N^{-n} (x_1 + x_2 + \dots + x_N)^n \rangle \\ &= \int_{-\infty}^{\infty} N^{-n} (x_1 + \dots + x_N)^n p(x_1) \dots p(x_N) dx_1 \dots dx_N, \end{aligned} \quad (4)$$

so we have

$$\begin{aligned} \mathcal{F}^{-1}[P_X(f)] &= \sum_{n=0}^{\infty} \frac{(2\pi i f)^n}{n!} \langle X^n \rangle \\ &= \sum_{n=0}^{\infty} \frac{(2\pi i f)^n}{n!} \int_{-\infty}^{\infty} N^{-n} (x_1 + \dots + x_N)^n \\ &\quad \times p(x_1) \dots p(x_N) dx_1 \dots dx_N \\ &= \int_{-\infty}^{\infty} \sum_{n=0}^{\infty} \left[ \frac{2\pi i f (x_1 + \dots + x_N)}{N} \right]^n \frac{1}{n!} \\ &\quad \times p(x_1) \dots p(x_N) dx_1 \dots dx_N \\ &= \int_{-\infty}^{\infty} e^{2\pi i f (x_1 + \dots + x_N)/N} p(x_1) \dots p(x_N) dx_1 \dots dx_N \\ &= \left[ \int_{-\infty}^{\infty} e^{2\pi i f x_1/N} p(x_1) dx_1 \right] \\ &\quad \times \dots \times \left[ \int_{-\infty}^{\infty} e^{2\pi i f x_N/N} p(x_N) dx_N \right] \\ &= \left[ \int_{-\infty}^{\infty} e^{2\pi i f x/N} p(x) dx \right]^N \\ &= \left\{ \int_{-\infty}^{\infty} \left[ 1 + \left( \frac{2\pi i f}{N} \right) x + \frac{1}{2} \left( \frac{2\pi i f}{N} \right)^2 x^2 + \dots \right] p(x) dx \right\}^N \\ &= \left[ \int_{-\infty}^{\infty} p(x) dx + \frac{2\pi i f}{N} \int_{-\infty}^{\infty} x p(x) dx \right. \\ &\quad \left. - \frac{(2\pi f)^2}{2N^2} \int_{-\infty}^{\infty} x^2 p(x) dx + \mathcal{O}(N^{-3}) \right]^N \\ &= \left[ 1 + \frac{2\pi i f}{N} \langle x \rangle - \frac{(2\pi f)^2}{2N^2} \langle x^2 \rangle + \mathcal{O}(N^{-3}) \right]^N \\ &= \exp \left\{ N \ln \left[ 1 + \frac{2\pi i f}{N} \langle x \rangle - \frac{(2\pi f)^2}{2N^2} \langle x^2 \rangle + \mathcal{O}(N^{-3}) \right] \right\}. \end{aligned} \quad (5)$$

Now expand

$$\ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 + \dots, \quad (6)$$

so

$$\begin{aligned} \mathcal{F}^{-1}[P_X(f)] &\approx \exp \left\{ N \left[ \frac{2\pi i f}{N} \langle x \rangle - \frac{(2\pi f)^2}{2N^2} \langle x^2 \rangle \right. \right. \\ &\quad \left. \left. + \frac{1}{2} \frac{(2\pi i f)^2}{N^2} \langle x \rangle^2 + \mathcal{O}(N^{-3}) \right] \right\} \\ &= \exp \left[ 2\pi i f \langle x \rangle - \frac{(2\pi f)^2 \langle x^2 \rangle - \langle x \rangle^2}{2N} + \mathcal{O}(N^{-2}) \right] \\ &\approx \exp \left[ 2\pi i f \mu_x - \frac{(2\pi f)^2 \sigma_x^2}{2N} \right], \end{aligned} \quad (7)$$

since

$$\mu_x \equiv \langle x \rangle \quad (8)$$

$$\sigma_x^2 \equiv \langle x^2 \rangle - \langle x \rangle^2. \quad (9)$$

Taking the FOURIER TRANSFORM,

$$\begin{aligned} P_X &\equiv \int_{-\infty}^{\infty} e^{-2\pi i f x} \mathcal{F}^{-1}[P_X(f)] df \\ &= \int_{-\infty}^{\infty} e^{2\pi i f(\mu_x - x) - (2\pi f)^2 \sigma_x^2 / 2N} df. \end{aligned} \quad (10)$$

This is of the form

$$\int_{-\infty}^{\infty} e^{iaf - bf^2} df, \quad (11)$$

where  $a \equiv 2\pi(\mu_x - x)$  and  $b \equiv (2\pi\sigma_x)^2/2N$ . But, from Abramowitz and Stegun (1972, p. 302, equation 7.4.6),

$$\int_{-\infty}^{\infty} e^{iaf - bf^2} df = e^{-a^2/4b} \sqrt{\frac{\pi}{b}}. \quad (12)$$

Therefore,

$$\begin{aligned} P_X &= \sqrt{\frac{\pi}{\frac{(2\pi\sigma_x)^2}{2N}}} \exp \left\{ -\frac{[2\pi(\mu_x - x)]^2}{4 \frac{(2\pi\sigma_x)^2}{2N}} \right\} \\ &= \sqrt{\frac{2\pi N}{4\pi^2 \sigma_x^2}} \exp \left[ -\frac{4\pi^2 (\mu_x - x)^2 2N}{4 \cdot 4\pi^2 \sigma_x^2} \right] \\ &= \frac{\sqrt{N}}{\sigma_x \sqrt{2\pi}} e^{-(\mu_x - x)^2 N / 2\sigma_x^2}. \end{aligned} \quad (13)$$

But  $\sigma_X = \sigma_x / \sqrt{N}$  and  $\mu_X = \mu_x$ , so

$$P_X = \frac{1}{\sigma_X \sqrt{2\pi}} e^{-(\mu_X - x)^2 / 2\sigma_X^2}. \quad (14)$$

The “fuzzy” central limit theorem says that data which are influenced by many small and unrelated random effects are approximately NORMALLY DISTRIBUTED.

#### Central Trinomial Coefficient

The  $n$ th central binomial coefficient is defined as the coefficient of  $x^n$  in the expansion of  $(1+x+x^2)^n$ . The first few are 1, 3, 7, 19, 51, 141, 393, ... (Sloane's A002426). This sequence cannot be expressed as a fixed number of hypergeometric terms (Petkovšek *et al.* 1996, p. 160). The GENERATING FUNCTION is given by

$$f(x) = \frac{1}{\sqrt{(1+x)(1-3x)}} = 1 + x + 3x^2 + 7x^3 + \dots$$

see also CENTRAL BINOMIAL COEFFICIENT

#### Centralizer

The centralizer of a FINITE non-ABELIAN SIMPLE GROUP  $G$  is an element  $z$  of order 2 such that

$$C_G(z) = \{g \in G : gz = zg\}.$$

see also CENTER (GROUP), NORMALIZER

#### Centrode

$$\mathbf{C} \equiv \tau \mathbf{T} + \kappa \mathbf{B},$$

where  $\tau$  is the TORSION,  $\kappa$  is the CURVATURE,  $\mathbf{T}$  is the TANGENT VECTOR, and  $\mathbf{B}$  is the BINORMAL VECTOR.

#### Centroid (Function)

By analogy with the GEOMETRIC CENTROID, the centroid of an arbitrary function  $f(x)$  is defined as

$$\langle x \rangle = \frac{\int_{-\infty}^{\infty} x f(x) dx}{\int_{-\infty}^{\infty} f(x) dx}.$$

#### References

- Bracewell, R. *The Fourier Transform and Its Applications*. New York: McGraw-Hill, pp. 139–140 and 156, 1965.

#### Centroid (Geometric)

The CENTER OF MASS of a 2-D planar LAMINA or a 3-D solid. The mass of a LAMINA with surface density function  $\sigma(x, y)$  is

$$M = \iint \sigma(x, y) dA. \quad (1)$$

The coordinates of the centroid (also called the CENTER OF GRAVITY) are

$$\bar{x} = \frac{\iint x \sigma(x, y) dA}{M} \quad (2)$$

$$\bar{y} = \frac{\iint y \sigma(x, y) dA}{M}. \quad (3)$$

The centroids of several common laminas along the non-symmetrical axis are summarized in the following table.

Figure	$\bar{y}$
parabolic segment	$\frac{3}{5}h$
semicircle	$\frac{4r}{3\pi}$

In 3-D, the mass of a solid with density function  $\rho(x, y, z)$  is

$$M = \iiint \rho(x, y, z) dV, \quad (4)$$

and the coordinates of the center of mass are

$$\bar{x} = \frac{\iiint x \rho(x, y, z) dV}{M} \quad (5)$$

$$\bar{y} = \frac{\iiint y \rho(x, y, z) dV}{M} \quad (6)$$

$$\bar{z} = \frac{\iiint z \rho(x, y, z) dV}{M}. \quad (7)$$

Figure	$\bar{z}$
cone	$\frac{1}{4}h$
conical frustum	$\frac{h(R_1^2 + 2R_1R_2 + 3R_2^2)}{4(R_1^2 + R_1R_2 + R_2^2)}$
hemisphere	$\frac{3}{8}R$
paraboloid	$\frac{2}{3}h$
pyramid	$\frac{1}{4}h$

### Centroid (Orthocentric System)

The centroid of the four points constituting an ORTHOCENTRIC SYSTEM is the center of the common NINE-POINT CIRCLE (Johnson 1929, p. 249). This fact automatically guarantees that the centroid of the INCENTER and EXCENTERS of a TRIANGLE is located at the CIRCUMCENTER.

### References

- Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, 1929.

### Centroid (Triangle)

The centroid (CENTER OF MASS) of the VERTICES of a TRIANGLE is the point  $M$  (or  $G$ ) of intersection of the TRIANGLE'S three MEDIANS, also called the MEDIAN POINT (Johnson 1929, p. 249). The centroid is always in the interior of the TRIANGLE, and has TRILINEAR COORDINATES

$$\frac{1}{a} : \frac{1}{b} : \frac{1}{c}, \quad (1)$$

or

$$\csc A : \csc B : \csc C. \quad (2)$$

If the sides of a TRIANGLE are divided so that

$$\frac{\overline{A_2P_1}}{\overline{P_1A_3}} = \frac{\overline{A_3P_2}}{\overline{P_2A_1}} = \frac{\overline{A_1P_3}}{\overline{P_3A_2}} = \frac{p}{q}, \quad (3)$$

the centroid of the TRIANGLE  $\Delta P_1P_2P_3$  is  $M$  (Johnson 1929, p. 250).

Pick an interior point  $X$ . The TRIANGLES  $BXC$ ,  $CXA$ , and  $AXB$  have equal areas IFF  $X$  corresponds to the centroid. The centroid is located one third of the way from each VERTEX to the MIDPOINT of the opposite side. Each median divides the triangle into two equal areas; all the medians together divide it into six equal parts, and the lines from the MEDIAN POINT to the VERTICES divide the whole into three equivalent TRIANGLES. In general, for any line in the plane of a TRIANGLE  $ABC$ ,

$$d = \frac{1}{3}(d_A + d_B + d_C), \quad (4)$$

where  $d$ ,  $d_A$ ,  $d_B$ , and  $d_C$  are the distances from the centroid and VERTICES to the line. A TRIANGLE will balance at the centroid, and along any line passing through the centroid. The TRILINEAR POLAR of the centroid is called the LEMOINE AXIS. The PERPENDICULARS from the centroid are proportional to  $s_i^{-1}$ ,

$$a_1p_2 = a_2p_2 = a_3p_3 = \frac{2}{3}\Delta, \quad (5)$$

where  $\Delta$  is the AREA of the TRIANGLE. Let  $P$  be an arbitrary point, the VERTICES be  $A_1$ ,  $A_2$ , and  $A_3$ , and the centroid  $M$ . Then

$$\overline{PA_1}^2 + \overline{PA_2}^2 + \overline{PA_3}^2 = \overline{MA_1}^2 + \overline{MA_2}^2 + \overline{MA_3}^2 + 3\overline{PM}^2. \quad (6)$$

If  $O$  is the CIRCUMCENTER of the triangle's centroid, then

$$\overline{OM}^2 = R^2 - \frac{1}{9}(a^2 + b^2 + c^2). \quad (7)$$

The centroid lies on the EULER LINE.

The centroid of the PERIMETER of a TRIANGLE is the triangle's SPIEKER CENTER (Johnson 1929, p. 249).

### Cesàro Mean

see FEJES TÓTH'S INTEGRAL

### Ceva's Theorem

Given a TRIANGLE with VERTICES  $A$ ,  $B$ , and  $C$  and points along the sides  $D$ ,  $E$ , and  $F$ , a NECESSARY and SUFFICIENT condition for the CEVIANS  $AD$ ,  $BE$ , and  $CF$  to be CONCURRENT (intersect in a single point) is that

$$BD \cdot CE \cdot AF = DC \cdot EA \cdot FB. \quad (1)$$

Let  $P = [V_1, \dots, V_n]$  be an arbitrary  $n$ -gon,  $C$  a given point, and  $k$  a POSITIVE INTEGER such that  $1 \leq k \leq n/2$ . For  $i = 1, \dots, n$ , let  $W_i$  be the intersection of the lines  $CV_i$  and  $V_{i-k}V_{i+k}$ , then

$$\prod_{i=1}^n \left[ \frac{V_{i-k}W_i}{W_iV_{i+k}} \right] = 1. \quad (2)$$

Here,  $AB||CD$  and

$$\left[ \frac{AB}{CD} \right] \quad (3)$$

is the RATIO of the lengths  $[A, B]$  and  $[C, D]$  with a plus or minus sign depending on whether these segments have the same or opposite directions (Grünbaum and Shepard 1995).

Another form of the theorem is that three CONCURRENT lines from the VERTICES of a TRIANGLE divide the opposite sides in such fashion that the product of three nonadjacent segments equals the product of the other three (Johnson 1929, p. 147).

## Cevian Triangle

Given a center  $\alpha : \beta : \gamma$ , the cevian triangle is defined as that with VERTICES  $0 : \beta : \gamma$ ,  $\alpha : 0 : \gamma$ , and  $\alpha : \beta : 0$ . If  $A'B'C'$  is the CEVIAN TRIANGLE of  $X$  and  $A''B''C''$  is the ANTICEVIAN TRIANGLE, then  $X$  and  $A''$  are HARMONIC CONJUGATE POINTS with respect to  $A$  and  $A'$ .

see also ANTICEVIAN TRIANGLE

## Chain

Let  $P$  be a finite PARTIALLY ORDERED SET. A chain in  $P$  is a set of pairwise comparable elements (i.e., a TOTALLY ORDERED subset). The WIDTH of  $P$  is the maximum CARDINALITY of an ANTICHAIN in  $P$ . For a PARTIAL ORDER, the size of the longest CHAIN is called the WIDTH.

see also ADDITION CHAIN, ANTICHAIN, BRAUER CHAIN, CHAIN (GRAPH), DILWORTH'S LEMMA, HANSEN CHAIN

## Chain Fraction

see CONTINUED FRACTION

## Chain (Graph)

A chain of a GRAPH is a SEQUENCE  $\{x_1, x_2, \dots, x_n\}$  such that  $(x_1, x_2), (x_2, x_3), \dots, (x_{n-1}, x_n)$  are EDGES of the GRAPH.

## Chain Rule

If  $g(x)$  is DIFFERENTIABLE at the point  $x$  and  $f(x)$  is DIFFERENTIABLE at the point  $g(x)$ , then  $f \circ g$  is DIFFERENTIABLE at  $x$ . Furthermore, let  $y = f(g(x))$  and  $u = g(x)$ , then

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}. \quad (1)$$

There are a number of related results which also go under the name of "chain rules." For example, if  $z = f(x, y)$ ,  $x = g(t)$ , and  $y = h(t)$ , then

$$\frac{dz}{dt} = \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt}. \quad (2)$$

The "general" chain rule applies to two sets of functions

$$y_1 = f_1(u_1, \dots, u_p)$$

$$\vdots (3)$$

$$y_m = f_m(u_1, \dots, u_p)$$

and

$$u_1 = g_1(x_1, \dots, x_n)$$

$$\vdots (4)$$

$$u_p = g_p(x_1, \dots, x_n).$$

Defining the  $m \times n$  JACOBI MATRIX by

$$\left( \frac{\partial y_i}{\partial x_j} \right) = \begin{bmatrix} \frac{\partial y_1}{\partial x_1} & \frac{\partial y_1}{\partial x_2} & \cdots & \frac{\partial y_1}{\partial x_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial y_m}{\partial x_1} & \frac{\partial y_m}{\partial x_2} & \cdots & \frac{\partial y_m}{\partial x_n} \end{bmatrix}, \quad (5)$$

and similarly for  $(\partial y_i / \partial u_j)$  and  $(\partial u_i / \partial x_j)$  then gives

$$\left( \frac{\partial y_i}{\partial x_j} \right) = \left( \frac{\partial y_i}{\partial u_j} \right) \left( \frac{\partial u_i}{\partial x_j} \right). \quad (6)$$

In differential form, this becomes

$$dy_1 = \left( \frac{\partial y_1}{\partial u_1} \frac{\partial u_1}{\partial x_1} + \dots + \frac{\partial y_1}{\partial u_p} \frac{\partial u_p}{\partial x_1} \right) dx_1 \\ + \left( \frac{\partial y_1}{\partial u_1} \frac{\partial u_1}{\partial x_2} + \dots + \frac{\partial y_1}{\partial u_p} \frac{\partial u_p}{\partial x_2} \right) dx_2 + \dots \quad (7)$$

(Kaplan 1984).

### Champernowne Constant

Champernowne's number 0.1234567891011... (Sloane's A033307) is the decimal obtained by concatenating the POSITIVE INTEGERS. It is NORMAL in base 10. In 1961, Mahler showed it to also be TRANSCENDENTAL.

The CONTINUED FRACTION of the Champernowne constant is [0, 8, 9, 1, 149083, 1, 1, 1, 4, 1, 1, 1, 3, 4, 1, 1, 1, 15,

457540111391031076483646628242956118599603939...  
 710457555000662004393090262659256314937953207...  
 747128656313864120937550355209460718308998457...  
 5801469863148833592141783010987,

6, 1, 1, 21, 1, 9, 1, 1, 2, 3, 1, 7, 2, 1, 83, 1, 156, 4, 58, 8, 54, ...] (Sloane's A030167). The next term of the CONTINUED FRACTION is huge, having 2504 digits. In fact, the coefficients eventually become unbounded, making the continued fraction difficult to calculate for too many more terms. Large terms greater than  $10^5$  occur at positions 5, 19, 41, 102, 163, 247, 358, 460, ... and have 6, 166, 2504, 140, 33102, 109, 2468, 136, ... digits (Plouffe). Interestingly, the COPELAND-ERDŐS CONSTANT, which is the decimal obtained by concatenating the PRIMES, has a well-behaved CONTINUED FRACTION which does not show the "large term" phenomenon.

## Change of Variables Theorem

A theorem which effectively describes how lengths, areas, volumes, and generalized  $n$ -dimensional volumes (CONTENTS) are distorted by DIFFERENTIABLE FUNCTIONS. In particular, the change of variables theorem reduces the whole problem of figuring out the distortion of the content to understanding the infinitesimal distortion, i.e., the distortion of the DERIVATIVE (a linear MAP), which is given by the linear MAP's DETERMINANT. So  $f: \mathbb{R}^n \rightarrow \mathbb{R}^n$  is an AREA-PRESERVING linear MAP IFF  $|\det(f)| = 1$ , and in more generality, if  $S$  is any subset of  $\mathbb{R}^n$ , the CONTENT of its image is given by  $|\det(f)|$  times the CONTENT of the original. The change of variables theorem takes this infinitesimal knowledge, and applies CALCULUS by breaking up the DOMAIN into small pieces and adds up the change in AREA, bit by bit.

The change of variable formula persists to the generality of DIFFERENTIAL FORMS on MANIFOLDS, giving the formula

$$\int_M (f^* \omega) = \int_W (\omega)$$

under the conditions that  $M$  and  $W$  are compact connected oriented MANIFOLDS with nonempty boundaries,  $f: M \rightarrow W$  is a smooth map which is an orientation-preserving DIFFEOMORPHISM of the boundaries.

In 2-D, the explicit statement of the theorem is

$$\begin{aligned} \int_R f(x, y) dx dy \\ = \int_{R^*} f[x(u, v), y(u, v)] \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du dv \end{aligned}$$

and in 3-D, it is

$$\begin{aligned} \int_R f(x, y, z) dx dy dz \\ = \int_{R^*} f[x(u, v, w), y(u, v, w), z(u, v, w)] \left| \frac{\partial(x, y, z)}{\partial(u, v, w)} \right| du dv dw, \end{aligned}$$

where  $R = f(R^*)$  is the image of the original region  $R^*$ ,

$$\left| \frac{\partial(x, y, z)}{\partial(u, v, w)} \right|$$

is the JACOBIAN, and  $f$  is a global orientation-preserving DIFFEOMORPHISM of  $R$  and  $R^*$  (which are open subsets of  $\mathbb{R}^n$ ).

The change of variables theorem is a simple consequence of the CURL THEOREM and a little DE RHAM COHOMOLOGY. The generalization to  $n$ -D requires no additional assumptions other than the regularity conditions on the boundary.

## Chaos

A DYNAMICAL SYSTEM is chaotic if it

1. Has a DENSE collection of points with periodic orbits,
2. Is sensitive to the initial condition of the system (so that initially nearby points can evolve quickly into very different states), and
3. Is TOPOLOGICALLY TRANSITIVE.

Chaotic systems exhibit irregular, unpredictable behavior (the BUTTERFLY EFFECT). The boundary between linear and chaotic behavior is characterized by PERIOD DOUBLING, following by quadrupling, etc.

An example of a simple physical system which displays chaotic behavior is the motion of a magnetic pendulum over a plane containing two or more attractive magnets. The magnet over which the pendulum ultimately comes to rest (due to frictional damping) is highly dependent on the starting position and velocity of the pendulum (Dickau). Another such system is a double pendulum (a pendulum with another pendulum attached to its end).

### Chaos Game

Pick a point at random inside a regular  $n$ -gon. Then draw the next point a fraction  $r$  of the distance between it and a VERTEX picked at random. Continue the process (after throwing out the first few points). The result of this "chaos game" is sometimes, but not always, a FRACTAL. The case  $(n, r) = (4, 1/2)$  gives the interior of a SQUARE with all points visited with equal probability.

### Character (Group)

The GROUP THEORY term for what is known to physicists as the TRACE. All members of the same CONJUGACY CLASS in the same representation have the same character. Members of other CONJUGACY CLASSES may also have the same character, however. An (abstract) GROUP can be uniquely identified by a listing of the characters of its various representations, known as a CHARACTER TABLE. Some of the SCHÖNFLIES SYMBOLS denote different sets of symmetry operations but correspond to the same abstract GROUP and so have the same CHARACTER TABLES.

### Character (Multiplicative)

A continuous HOMEOMORPHISM of a GROUP into the NONZERO COMPLEX NUMBERS. A multiplicative character  $\omega$  gives a REPRESENTATION on the 1-D SPACE  $\mathbb{C}$  of COMPLEX NUMBERS, where the REPRESENTATION action by  $g \in G$  is multiplication by  $\omega(g)$ . A multiplicative character is UNITARY if it has ABSOLUTE VALUE 1 everywhere.

### References

### Character (Number Theory)

A number theoretic function  $\chi_k(n)$  for POSITIVE integral  $n$  is a character modulo  $k$  if

$$\begin{aligned}\chi_k(1) &= 1 \\ \chi_k(n) &= \chi_k(n+k) \\ \chi_k(m)\chi_k(n) &= \chi_k(mn)\end{aligned}$$

for all  $m, n$ , and

$$\chi_k(n) = 0$$

if  $(k, n) \neq 1$ .  $\chi_k$  can only assume values which are  $\phi(k)$  ROOTS OF UNITY, where  $\phi$  is the TOTIENT FUNCTION. see also DIRICHLET  $L$ -SERIES

### Characteristic Class

Characteristic classes are COHOMOLOGY classes in the BASE SPACE of a VECTOR BUNDLE, defined through OBSTRUCTION theory, which are (perhaps partial) obstructions to the existence of  $k$  everywhere linearly independent vector FIELDS on the VECTOR BUNDLE. The most common examples of characteristic classes are the CHERN, PONTRYAGIN, and STIEFEL-WHITNEY CLASSES.

### Characteristic (Elliptic Integral)

A parameter  $n$  used to specify an ELLIPTIC INTEGRAL OF THE THIRD KIND.

see also AMPLITUDE, ELLIPTIC INTEGRAL, MODULAR ANGLE, MODULUS (ELLIPTIC INTEGRAL), NOME, PARAMETER

### Characteristic Equation

The equation which is solved to find a MATRIX's EIGENVALUES, also called the CHARACTERISTIC POLYNOMIAL. Given a  $2 \times 2$  system of equations with MATRIX

$$M \equiv \begin{bmatrix} a & b \\ c & d \end{bmatrix}, \quad (1)$$

the MATRIX EQUATION is

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = t \begin{bmatrix} x \\ y \end{bmatrix}, \quad (2)$$

which can be rewritten

$$\begin{bmatrix} a-t & b \\ c & d-t \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = t \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \quad (3)$$

$M$  can have no MATRIX INVERSE, since otherwise

$$\begin{bmatrix} x \\ y \end{bmatrix} = M^{-1} \begin{bmatrix} 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad (4)$$

which contradicts our ability to pick arbitrary  $x$  and  $y$ . Therefore,  $M$  has no inverse, so its DETERMINANT is 0. This gives the characteristic equation

$$\begin{vmatrix} a-t & b \\ c & d-t \end{vmatrix} = 0, \quad (5)$$

where  $|A|$  denotes the DETERMINANT of  $A$ . For a general  $k \times k$  MATRIX

$$\begin{bmatrix} a_{11} & a_{12} & \dots & a_{1k} \\ a_{21} & a_{22} & \dots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \dots & a_{kk} \end{bmatrix}, \quad (6)$$

the characteristic equation is

$$\begin{vmatrix} a_{11}-t & a_{12} & \dots & a_{1k} \\ a_{21} & a_{22}-t & \dots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \dots & a_{kk}-t \end{vmatrix} = 0. \quad (7)$$

### Characteristic (Euler)

see EULER CHARACTERISTIC

### Characteristic Factor

A characteristic factor is a factor in a particular factorization of the TOTIENT FUNCTION  $\phi(n)$  such that the product of characteristic factors gives the representation of a corresponding abstract GROUP as a DIRECT PRODUCT. By computing the characteristic factors, any ABELIAN GROUP can be expressed as a DIRECT PRODUCT of CYCLIC SUBGROUPS, for example,  $Z_2 \otimes Z_4$  or  $Z_2 \otimes Z_2 \otimes Z_2$ . There is a simple algorithm for determining the characteristic factors of MODULO MULTIPLICATION GROUPS.

### Characteristic (Field)

For a FIELD  $K$  with multiplicative identity 1, consider the numbers  $2 = 1 + 1$ ,  $3 = 1 + 1 + 1$ ,  $4 = 1 + 1 + 1 + 1$ , etc. Either these numbers are all different, in which case we say that  $K$  has characteristic 0, or two of them will be equal. In this case, it is straightforward to show that, for some number  $p$ , we have  $\underbrace{1 + 1 + \dots + 1}_{p \text{ times}} = 0$ .

If  $p$  is chosen to be as small as possible, then  $p$  will be a PRIME, and we say that  $K$  has characteristic  $p$ . The FIELDS  $\mathbb{Q}$ ,  $\mathbb{R}$ ,  $\mathbb{C}$ , and the  $p$ -ADIC NUMBERS  $\mathbb{Q}_p$  have characteristic 0. For  $p$  a PRIME, the GALOIS FIELD  $\text{GF}(p^n)$  has characteristic  $p$ .

If  $H$  is a SUBFIELD of  $K$ , then  $H$  and  $K$  have the same characteristic.

see also FIELD, SUBFIELD

**Characteristic Function**

The characteristic function  $\phi(t)$  is defined as the FOURIER TRANSFORM of the PROBABILITY DENSITY FUNCTION,

$$\phi(t) = \mathcal{F}[P(x)] = \int_{-\infty}^{\infty} e^{itx} P(x) dx \quad (1)$$

$$= \int_{-\infty}^{\infty} P(x) dx + it \int_{-\infty}^{\infty} x P(x) dx + \frac{1}{2}(it)^2 \int_{-\infty}^{\infty} x^2 P(x) dx + \dots \quad (2)$$

$$= \sum_{k=0}^{\infty} \frac{(it)^k}{k!} \mu'_k \quad (3)$$

$$= 1 + it\mu'_1 - \frac{1}{2}t^2\mu'_2 - \frac{1}{3!}it^3\mu'_3 + \frac{1}{4!}t^4\mu'_4 + \dots, \quad (4)$$

where  $\mu'_n$  (sometimes also denoted  $\nu_n$ ) is the  $n$ th MOMENT about 0 and  $\mu'_0 \equiv 1$ . The characteristic function can therefore be used to generate MOMENTS about 0,

$$\phi^{(n)}(0) \equiv \left[ \frac{d^n \phi}{dt^n} \right]_{t=0} = i^n \mu'_n \quad (5)$$

or the CUMULANTS  $\kappa_n$ ,

$$\ln \phi(t) \equiv \sum_{n=0}^{\infty} \kappa_n \frac{(it)^n}{n!}. \quad (6)$$

A DISTRIBUTION is not uniquely specified by its MOMENTS, but is uniquely specified by its characteristic function.

**Characteristic (Partial Differential Equation)**

Paths in a 2-D plane used to transform PARTIAL DIFFERENTIAL EQUATIONS into systems of ORDINARY DIFFERENTIAL EQUATIONS. They were invented by Riemann. For an example of the use of characteristics, consider the equation

$$u_t - 6uu_x = 0.$$

Now let  $u(s) = u(x(s), t(s))$ . Since

$$\frac{du}{ds} = \frac{dx}{ds} u_x + \frac{dt}{ds} u_t,$$

it follows that  $dt/ds = 1$ ,  $dx/ds = -6u$ , and  $du/ds = 0$ . Integrating gives  $t(s) = s$ ,  $x(s) = -6su_0(x)$ , and  $u(s) = u_0(x)$ , where the constants of integration are 0 and  $u_0(x) = u(x, 0)$ .

**Characteristic Polynomial**

The expanded form of the CHARACTERISTIC EQUATION.

$$\det(xI - A),$$

where  $A$  is an  $n \times n$  MATRIX and  $I$  is the IDENTITY MATRIX.

see also CAYLEY-HAMILTON THEOREM

**Characteristic (Real Number)**

For a REAL NUMBER  $x$ ,  $[x] = \text{int}(x)$  is called the characteristic. Here,  $[x]$  is the FLOOR FUNCTION.

see also MANTISSA, SCIENTIFIC NOTATION

**Charlier's Check**

A check which can be used to verify correct computation of MOMENTS.

**Chasles-Cayley-Brill Formula**

The number of coincidences of a  $(\nu, \nu')$  correspondence of value  $\gamma$  on a curve of GENUS  $p$  is given by

$$\nu + \nu' + 2p\gamma.$$

**Chasles's Contact Theorem**

If a one-parameter family of curves has index  $N$  and class  $M$ , the number tangent to a curve of order  $n_1$  and class  $m_1$  in general position is

$$m_1 N + n_1 M.$$

**References**

- Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 436, 1959.

**Chasles's Polars Theorem**

If the TRILINEAR POLARS of the VERTICES of a TRIANGLE are distinct from the respectively opposite sides, they meet the sides in three COLLINEAR points.

see also COLLINEAR, TRIANGLE, TRILINEAR POLAR

**Chasles's Theorem**

If two projective PENCILS of curves of orders  $n$  and  $n'$  have no common curve, the LOCUS of the intersections of corresponding curves of the two is a curve of order  $n+n'$  through all the centers of either PENCIL. Conversely, if a curve of order  $n+n'$  contains all centers of a PENCIL of order  $n$  to the multiplicity demanded by NOETHER'S FUNDAMENTAL THEOREM, then it is the LOCUS of the intersections of corresponding curves of this PENCIL and one of order  $n'$  projective therewith.

see also NOETHER'S FUNDAMENTAL THEOREM, PENCIL

**References**

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 33, 1959.

**Chebyshev Approximation Formula**

Using a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND  $T$ , define

$$c_j \equiv \frac{2}{N} \sum_{k=1}^N f(x_k) T_j(x_k) \\ = \frac{2}{N} \sum_{k=1}^N f \left[ \cos \left\{ \frac{\pi(k-\frac{1}{2})}{N} \right\} \right] \cos \left\{ \frac{\pi j(k-\frac{1}{2})}{N} \right\}.$$

Then

$$f(x) \approx \sum_{k=0}^{N-1} c_k T_k(x) - \frac{1}{2} c_0.$$

It is exact for the  $N$  zeros of  $T_N(x)$ . This type of approximation is important because, when truncated, the error is spread smoothly over  $[-1, 1]$ . The Chebyshev approximation formula is very close to the MINIMAX POLYNOMIAL.

**Chebyshev Deviation**

$$\max_{a \leq x \leq b} \{|f(x) - \rho(x)|w(x)\}.$$

**References**

Szegő, G. *Orthogonal Polynomials*, 4th ed. Providence, RI: Amer. Math. Soc., p. 41, 1975.

**Chebyshev Differential Equation**

$$(1-x^2) \frac{d^2 y}{dx^2} - x \frac{dy}{dx} + m^2 y = 0 \quad (1)$$

for  $|x| < 1$ . The Chebyshev differential equation has regular SINGULARITIES at  $-1$ ,  $1$ , and  $\infty$ . It can be solved by series solution using the expansions

$$y = \sum_{n=0}^{\infty} a_n x^n \quad (2)$$

$$y' = \sum_{n=0}^{\infty} n a_n x^{n-1} = \sum_{n=1}^{\infty} n a_n x^{n-1} \\ = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n \quad (3)$$

$$y'' = \sum_{n=0}^{\infty} (n+1) n a_{n+1} x^{n-1} = \sum_{n=1}^{\infty} (n+1) n a_{n+1} x^{n-1} \\ = \sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n. \quad (4)$$

Now, plug (2-4) into the original equation (1) to obtain

$$(1-x^2) \sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n \\ - x \sum_{n=0}^{\infty} (n+1) n a_{n+1} x^{n-1} + m^2 \sum_{n=0}^{\infty} a_n x^n = 0 \quad (5)$$

$$\sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n - \sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^{n+2} \\ - \sum_{n=0}^{\infty} (n+1) a_{n+1} x^{n+1} + m^2 \sum_{n=0}^{\infty} a_n x^n = 0 \quad (6)$$

$$\sum_{n=0}^{\infty} (n+2)(n+1)a_{n+2}x^n - \sum_{n=2}^{\infty} n(n-1)a_nx^{n+2} - \sum_{n=1}^{\infty} na_nx^n + m^2 \sum_{n=0}^{\infty} a_nx^n = 0 \quad (7)$$

$$2 \cdot 1a_2 + 3 \cdot 2a_3x - 1 \cdot ax + m^2a_0 + m^2a_1x + \sum_{n=2}^{\infty} [(n+2)(n+1)a_{n+2} - n(n-1)a_n - na_n + m^2a_n]x^n = 0 \quad (8)$$

$$(2a_2 + m^2a_0) + [(m^2 - 1)a_1 + 6a_3]x + \sum_{n=2}^{\infty} [(n+2)(n+1)a_{n+2} + (m^2 - n^2)a_n]x^n = 0, \quad (9)$$

so

$$2a_2 + m^2a_0 = 0 \quad (10)$$

$$(m^2 - 1)a_1 + 6a_3 = 0 \quad (11)$$

$$a_{n+2} = \frac{n^2 - m^2}{(n+1)(n+2)}a_n \quad \text{for } n = 2, 3, \dots \quad (12)$$

The first two are special cases of the third, so the general recurrence relation is

$$a_{n+2} = \frac{n^2 - m^2}{(n+1)(n+2)}a_n \quad \text{for } n = 0, 1, \dots \quad (13)$$

From this, we obtain for the EVEN COEFFICIENTS

$$a_2 = -\frac{1}{2}m^2a_0 \quad (14)$$

$$a_4 = \frac{2^2 - m^2}{3 \cdot 4}a_2 = \frac{(2^2 - m^2)(-m^2)}{1 \cdot 2 \cdot 3 \cdot 4}a_0 \quad (15)$$

$$a_{2n} = \frac{[(2n)^2 - m^2][(2n-2)^2 - m^2] \cdots [1^2 - m^2]}{(2n)!}a_0, \quad (16)$$

and for the ODD COEFFICIENTS

$$a_3 = \frac{1 - m^2}{6}a_0 \quad (17)$$

$$a_5 = \frac{3^2 - m^2}{4 \cdot 5}a_3 = \frac{(3^2 - m^2)(1^2 - m^2)}{5!}a_1 \quad (18)$$

$$a_{2n-1} = \frac{[(2n-1)^2 - m^2][(2n-3)^2 - m^2] \cdots [1^2 - m^2]}{(2n+1)!}a_1. \quad (19)$$

So the general solution is

$$y = a_0 \left[ 1 + \sum_{k=2,4,\dots}^{\infty} \frac{[k^2 - m^2][(k-2)^2 - m^2] \cdots [-m^2]}{k!} x^k \right] + a_1 \left[ x + \sum_{k=3,5,\dots}^{\infty} \frac{[(k-2)^2 - m^2][(k-2)^2 - m^2] \cdots [1^2 - m^2]}{k!} x^k \right] \quad (20)$$

If  $n$  is EVEN, then  $y_1$  terminates and is a POLYNOMIAL solution, whereas if  $n$  is ODD, then  $y_2$  terminates and is a POLYNOMIAL solution. The POLYNOMIAL solutions defined here are known as CHEBYSHEV POLYNOMIALS OF THE FIRST KIND. The definition of the CHEBYSHEV POLYNOMIAL OF THE SECOND KIND gives a similar, but distinct, recurrence relation

$$a'_{n+2} = \frac{(n+1)^2 - m^2}{(n+2)(n+3)}a'_n \quad \text{for } n = 0, 1, \dots \quad (21)$$

### Chebyshev Function

$$\theta(x) \equiv \sum_{p \leq x} \ln p,$$

where the sum is over PRIMES  $p$ , so

$$\lim_{x \rightarrow \infty} \frac{x}{\theta(x)} = 1.$$

### Chebyshev-Gauss Quadrature

Also called CHEBYSHEV QUADRATURE. A GAUSSIAN QUADRATURE over the interval  $[-1, 1]$  with WEIGHTING FUNCTION  $W(x) = 1/\sqrt{1-x^2}$ . The ABSCISSAS for quadrature order  $n$  are given by the roots of the CHEBYSHEV POLYNOMIAL OF THE FIRST KIND  $T_n(x)$ , which occur symmetrically about 0. The WEIGHTS are

$$w_i = -\frac{A_{n+1}\gamma_n}{A_n T'_n(x_i) T_{n+1}(x_i)} = \frac{A_n}{A_{n-1}} \frac{\gamma_{n-1}}{T_{n-1}(x_i) T'_n(x_i)}, \quad (1)$$

where  $A_n$  is the COEFFICIENT of  $x^n$  in  $T_n(x)$ . For HERMITE POLYNOMIALS,

$$A_n = 2^{n-1}, \quad (2)$$

so

$$\frac{A_{n+1}}{A_n} = 2. \quad (3)$$

Additionally,

$$\gamma_n = \frac{1}{2}\pi, \quad (4)$$

so

$$w_i = -\frac{\pi}{T_{n+1}(x_i) T'_n(x_i)}. \quad (5)$$

Since

$$T_n(x) = \cos(n \cos^{-1} x), \quad (6)$$

the ABSCISSAS are given explicitly by

$$x_i = \cos \left[ \frac{(2i-1)\pi}{2n} \right]. \quad (7)$$

Since

$$T'_n(x_i) = \frac{(-1)^{i+1}n}{\alpha_i} \quad (8)$$

$$T_{n+1}(x_i) = (-1)^i \sin \alpha_i, \quad (9)$$

where

$$\alpha_i = \frac{(2i-1)\pi}{2n}, \quad (10)$$

all the WEIGHTS are

$$w_i = \frac{\pi}{n}. \quad (11)$$

The explicit FORMULA is then

$$\begin{aligned} & \int_{-1}^1 \frac{f(x) dx}{\sqrt{1-x^2}} \\ &= \frac{\pi}{n} \sum_{k=1}^n f \left[ \cos \left( \frac{2k-1}{2n} \pi \right) \right] + \frac{2\pi}{2^{2n}(2n)!} f^{(2n)}(\xi). \end{aligned} \quad (12)$$

$n$	$x_i$	$w_i$
2	$\pm 0.707107$	1.5708
3	0	1.0472
	$\pm 0.866025$	1.0472
4	$\pm 0.382683$	0.785398
	$\pm 0.92388$	0.785398

### Chebyshev Inequality

Apply MARKOV'S INEQUALITY with  $a \equiv k^2$  to obtain

$$P[(x - \mu)^2 \geq k^2] \leq \frac{\langle (x - \mu)^2 \rangle}{k^2} = \frac{\sigma^2}{k^2}. \quad (1)$$

Therefore, if a RANDOM VARIABLE  $x$  has a finite MEAN  $\mu$  and finite VARIANCE  $\sigma^2$ , then  $\forall k \geq 0$ ,

$$P(|x - \mu| \geq k) \leq \frac{\sigma^2}{k^2} \quad (2)$$

$$P(|x - \mu| \geq k\sigma) \leq \frac{1}{k^2}. \quad (3)$$

### Chebyshev Phenomenon

see PRIME QUADRATIC EFFECT

### Chebyshev Polynomial of the First Kind

A set of ORTHOGONAL POLYNOMIALS defined as the solutions to the CHEBYSHEV DIFFERENTIAL EQUATION and denoted  $T_n(x)$ . They are used as an approximation to a LEAST SQUARES FIT, and are a special case of the ULTRASPHERICAL POLYNOMIAL with  $\alpha = 0$ . The Chebyshev polynomials of the first kind  $T_n(x)$  are illustrated above for  $x \in [0, 1]$  and  $n = 1, 2, \dots, 5$ .

The Chebyshev polynomials of the first kind can be obtained from the generating functions

$$g_1(t, x) \equiv \frac{1-t^2}{1-2xt+t^2} = T_0(x) + 2 \sum_{n=1}^{\infty} T_n(x) t^n \quad (1)$$

and

$$g_2(t, x) \equiv \frac{1-xt}{1-2xt+t^2} = \sum_{n=0}^{\infty} T_n(x) t^n \quad (2)$$

for  $|x| \leq 1$  and  $|t| < 1$  (Beeler *et al.* 1972, Item 15). (A closely related GENERATING FUNCTION is the basis for the definition of CHEBYSHEV POLYNOMIAL OF THE SECOND KIND.) They are normalized such that  $T_n(1) = 1$ . They can also be written

$$T_n(x) = \frac{n}{2} \sum_{r=0}^{\lfloor n/2 \rfloor} \frac{(-1)^r}{n-r} \binom{n-r}{r} (2x)^{n-2r}, \quad (3)$$

or in terms of a DETERMINANT

$$T_n = \begin{vmatrix} x & 1 & 0 & 0 & \cdots & 0 & 0 \\ 1 & 2x & 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 2x & 1 & \cdots & 0 & 0 \\ 0 & 0 & 1 & 2x & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 & 2x \end{vmatrix}. \quad (4)$$

In closed form,

$$T_n(x) = \cos(n \cos^{-1} x) = \sum_{m=0}^{\lfloor n/2 \rfloor} \binom{n}{2m} x^{n-2m} (x^2 - 1)^m, \quad (5)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT and  $\lfloor x \rfloor$  is the FLOOR FUNCTION. Therefore, zeros occur when

$$x = \cos \left[ \frac{\pi(k - \frac{1}{2})}{n} \right] \quad (6)$$

for  $k = 1, 2, \dots, n$ . Extrema occur for

$$x = \cos \left( \frac{\pi k}{n} \right), \quad (7)$$

where  $k = 0, 1, \dots, n$ . At maximum,  $T_n(x) = 1$ , and at minimum,  $T_n(x) = -1$ . The Chebyshev POLYNOMIALS are ORTHONORMAL with respect to the WEIGHTING FUNCTION  $(1 - x^2)^{-1/2}$

$$\int_{-1}^1 \frac{T_m(x) T_n(x) dx}{\sqrt{1 - x^2}} = \begin{cases} \frac{1}{2} \pi \delta_{nm} & \text{for } m \neq 0, n \neq 0 \\ \pi & \text{for } m = n = 0, \end{cases} \quad (8)$$

where  $\delta_{mn}$  is the KRONECKER DELTA. Chebyshev polynomials of the first kind satisfy the additional discrete identity

$$\sum_{k=1}^m T_i(x_k) T_j(x_k) = \begin{cases} \frac{1}{2} m \delta_{ij} & \text{for } i \neq 0, j \neq 0 \\ m & \text{for } i = j = 0, \end{cases} \quad (9)$$

where  $x_k$  for  $k = 1, \dots, m$  are the  $m$  zeros of  $T_m(x)$ . They also satisfy the RECURRENCE RELATIONS

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x) \quad (10)$$

$$T_{n+1}(x) = xT_n(x) - \sqrt{(1 - x^2)\{1 - [T_n(x)]^2\}} \quad (11)$$

for  $n \geq 1$ . They have a COMPLEX integral representation

$$T_n(x) = \frac{1}{4\pi i} \int_{\gamma} \frac{(1 - z^2) z^{-n-1} dz}{1 - 2xz + z^2} \quad (12)$$

and a Rodrigues representation

$$T_n(x) = \frac{(-1)^n \sqrt{\pi} (1 - x^2)^{1/2}}{2n(n - \frac{1}{2})!} \frac{d^n}{dx^n} [(1 - x^2)^{n-1/2}]. \quad (13)$$

Using a FAST FIBONACCI TRANSFORM with multiplication law

$$(A, B)(C, D) = (AD + BC + 2xAC, BD - AC) \quad (14)$$

gives

$$(T_{n+1}(x), -T_n(x)) = (T_1(x), -T_0(x))(1, 0)^n. \quad (15)$$

Using GRAM-SCHMIDT ORTHONORMALIZATION in the range  $(-1, 1)$  with WEIGHTING FUNCTION  $(1 - x^2)^{(-1/2)}$  gives

$$p_0(x) = 1 \quad (16)$$

$$\begin{aligned} p_1(x) &= \left[ x - \frac{\int_{-1}^1 x(1 - x^2)^{-1/2} dx}{\int_{-1}^1 (1 - x^2)^{-1/2} dx} \right] \\ &= x - \frac{[-(1 - x^2)^{1/2}]_{-1}^1}{[\sin^{-1} x]_{-1}^1} = x \end{aligned} \quad (17)$$

$$\begin{aligned} p_2(x) &= \left[ x - \frac{\int_{-1}^1 x^3(1 - x^2)^{-1/2} dx}{\int_{-1}^1 x^2(1 - x^2)^{-1/2} dx} \right] x \\ &\quad - \left[ \frac{\int_{-1}^1 x^2(1 - x^2)^{-1/2} dx}{\int_{-1}^1 (1 - x^2)^{-1/2} dx} \right] \cdot 1 \\ &= [x - 0]x - \frac{\pi}{2} = x^2 - \frac{1}{2}, \end{aligned} \quad (18)$$

etc. Normalizing such that  $T_n(1) = 1$  gives

$$\begin{aligned} T_0(x) &= 1 \\ T_1(x) &= x \\ T_2(x) &= 2x^2 - 1 \\ T_3(x) &= 4x^3 - 3x \\ T_4(x) &= 8x^4 - 8x^2 + 1 \\ T_5(x) &= 16x^5 - 20x^3 + 5x \\ T_6(x) &= 32x^6 - 48x^4 + 18x^2 - 1. \end{aligned}$$

The Chebyshev polynomial of the first kind is related to the BESSEL FUNCTION OF THE FIRST KIND  $J_n(x)$  and MODIFIED BESSEL FUNCTION OF THE FIRST KIND  $I_n(x)$  by the relations

$$J_n(x) = i^n T_n \left( i \frac{d}{dx} \right) J_0(x) \quad (19)$$

$$I_n(x) = T_n \left( \frac{d}{dx} \right) I_0(x). \quad (20)$$

Letting  $x \equiv \cos \theta$  allows the Chebyshev polynomials of the first kind to be written as

$$T_n(x) = \cos(n\theta) = \cos(n \cos^{-1} x). \quad (21)$$

The second linearly dependent solution to the transformed differential equation

$$\frac{d^2 T_n}{d\theta^2} + n^2 T_n = 0 \quad (22)$$

is then given by

$$V_n(x) = \sin(n\theta) = \sin(n \cos^{-1} x), \quad (23)$$

which can also be written

$$V_n(x) = \sqrt{1-x^2} U_{n-1}(x), \quad (24)$$

where  $U_n$  is a CHEBYSHEV POLYNOMIAL OF THE SECOND KIND. Note that  $V_n(x)$  is therefore *not* a POLYNOMIAL.

The POLYNOMIAL

$$x^n - 2^{1-n} T_n(x) \quad (25)$$

(of degree  $n-2$ ) is the POLYNOMIAL of degree  $< n$  which stays closest to  $x^n$  in the interval  $(-1, 1)$ . The maximum deviation is  $2^{1-n}$  at the  $n+1$  points where

$$x = \cos\left(\frac{k\pi}{n}\right), \quad (26)$$

for  $k = 0, 1, \dots, n$  (Beeler *et al.* 1972, Item 15).

#### Chebyshev Polynomial of the Second Kind

A modified set of Chebyshev POLYNOMIALS defined by a slightly different GENERATING FUNCTION. Used to develop four-dimensional SPHERICAL HARMONICS in angular momentum theory. They are also a special case of the ULTRASPHERICAL POLYNOMIAL with  $\alpha = 1$ . The Chebyshev polynomials of the second kind  $U_n(x)$  are illustrated above for  $x \in [0, 1]$  and  $n = 1, 2, \dots, 5$ .

The defining GENERATING FUNCTION of the Chebyshev polynomials of the second kind is

$$g_2(t, x) = \frac{1}{1-2xt+t^2} = \sum_{n=0}^{\infty} U_n(x) t^n \quad (1)$$

for  $|x| < 1$  and  $|t| < 1$ . To see the relationship to a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND ( $T$ ), take  $\partial g / \partial t$ ,

$$\begin{aligned} \frac{\partial g}{\partial t} &= -(1-2xt+t^2)^{-2}(-2x+2t) \\ &= 2(t-x)(1-2xt+t^2)^{-2} \\ &= \sum_{n=0}^{\infty} n U_n(x) t^{n-1}. \end{aligned} \quad (2)$$

Multiply (2) by  $t$ ,

$$(2t^2-2xt)(1-2xt+t^2)^{-2} = \sum_{n=0}^{\infty} n U_n(x) t^n \quad (3)$$

and take (3)-(2),

$$\begin{aligned} \frac{(2t^2-2tx)-(1-2xt+t^2)}{(1-2xt+t^2)^2} &= \frac{t^2-1}{(1-2xt+t^2)^2} \\ &= \sum_{n=0}^{\infty} (n-1) U_n(x) t^n. \end{aligned} \quad (4)$$

The Rodrigues representation is

$$U_n(x) = \frac{(-1)^n (n+1) \sqrt{\pi}}{2^{n+1} (n+\frac{1}{2})! (1-x^2)^{1/2}} \frac{d^n}{dx^n} [(1-x^2)^{n+1/2}]. \quad (5)$$

The polynomials can also be written

$$\begin{aligned} U_n(x) &= \sum_{r=0}^{\lfloor n/2 \rfloor} (-1)^r \binom{n-r}{r} (2x)^{n-2r} \\ &= \sum_{m=0}^{\lfloor n/2 \rfloor} \binom{n+1}{2m+1} x^{n-2m} (x^2-1)^m, \end{aligned} \quad (6)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION and  $\lceil x \rceil$  is the CEILING FUNCTION, or in terms of a DETERMINANT

$$U_n = \begin{vmatrix} 2x & 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 2x & 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 2x & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 & 2x \end{vmatrix}. \quad (7)$$

The first few POLYNOMIALS are

$$\begin{aligned} U_0(x) &= 1 \\ U_1(x) &= 2x \\ U_2(x) &= 4x^2 - 1 \\ U_3(x) &= 8x^3 - 4x \\ U_4(x) &= 16x^4 - 12x^2 + 1 \\ U_5(x) &= 32x^5 - 32x^3 + 6x \\ U_6(x) &= 64x^6 - 80x^4 + 24x^2 - 1. \end{aligned}$$

Letting  $x \equiv \cos \theta$  allows the Chebyshev polynomials of the second kind to be written as

$$U_n(x) = \frac{\sin[(n+1)\theta]}{\sin \theta}. \quad (8)$$

The second linearly dependent solution to the transformed differential equation is then given by

$$W_n(x) = \frac{\cos[(n+1)\theta]}{\sin \theta}, \quad (9)$$

which can also be written

$$W_n(x) = (1-x^2)^{-1/2} T_{n+1}(x), \quad (10)$$

where  $T_n$  is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND. Note that  $W_n(x)$  is therefore *not* a POLYNOMIAL. *see also* CHEBYSHEV APPROXIMATION FORMULA, CHEBYSHEV POLYNOMIAL OF THE FIRST KIND, ULTRA-SPHERICAL POLYNOMIAL

#### Chebyshev Quadrature

A GAUSSIAN QUADRATURE-like FORMULA for numerical estimation of integrals. It uses WEIGHTING FUNCTION  $W(x) = 1$  in the interval  $[-1, 1]$  and forces all the weights to be equal. The general FORMULA is

$$\int_{-1}^1 f(x) dx = \frac{2}{n} \sum_{i=1}^n f(x_i).$$

The ABSCISSAS are found by taking terms up to  $y^n$  in the MACLAURIN SERIES of

$$s_n(y) = \exp \left\{ \frac{1}{2}n \left[ -2 + \ln(1-y) \left( 1 - \frac{1}{y} \right) + \ln(1+y) \left( 1 + \frac{1}{y} \right) \right] \right\},$$

and then defining

$$G_n(x) \equiv x^n s_n \left( \frac{1}{x} \right).$$

The ROOTS of  $G_n(x)$  then give the ABSCISSAS. The first few values are

$$\begin{aligned} G_0(x) &= 1 \\ G_1(x) &= x \\ G_2(x) &= \frac{1}{3}(3x^2 - 1) \\ G_3(x) &= \frac{1}{2}(2x^3 - x) \\ G_4(x) &= \frac{1}{45}(45x^4 - 30x^2 + 1) \\ G_5(x) &= \frac{1}{72}(72x^5 - 60x^3 + 7x) \\ G_6(x) &= \frac{1}{105}(105x^6 - 105x^4 + 21x^2 - 1) \\ G_7(x) &= \frac{1}{6480}(6480x^7 - 7560x^5 + 2142x^3 - 149x) \\ G_8(x) &= \frac{1}{42525}(42525x^8 - 56700x^6 + 20790x^4 - 2220x^2 - 43) \\ G_9(x) &= \frac{1}{22400}(22400x^9 - 33600x^7 + 15120x^5 - 2280x^3 + 53x). \end{aligned}$$

Because the ROOTS are all REAL for  $n \leq 7$  and  $n = 9$  only (Hildebrand 1956), these are the only permissible orders for Chebyshev quadrature. The error term is

$$E_n = \begin{cases} c_n \frac{f^{(n+1)}(\xi)}{(n+1)!} & n \text{ odd} \\ c_n \frac{f^{(n+2)}(\xi)}{(n+2)!} & n \text{ even,} \end{cases}$$

where

$$c_n = \begin{cases} \int_{-1}^1 x G_n(x) dx & n \text{ odd} \\ \int_{-1}^1 x^2 G_n(x) dx & n \text{ even.} \end{cases}$$

The first few values of  $c_n$  are 2/3, 8/45, 1/15, 32/945, 13/756, and 16/1575 (Hildebrand 1956). Beyer (1987) gives abscissas up to  $n = 7$  and Hildebrand (1956) up to  $n = 9$ .

$n$	$x_i$
2	$\pm 0.57735$
3	0 $\pm 0.707107$
4	$\pm 0.187592$ $\pm 0.794654$
5	0 $\pm 0.374541$ $\pm 0.832497$
6	$\pm 0.266635$ $\pm 0.422519$ $\pm 0.866247$
7	0 $\pm 0.323912$ $\pm 0.529657$ $\pm 0.883862$
9	0 $\pm 0.167906$ $\pm 0.528762$ $\pm 0.601019$ $\pm 0.911589$

The ABSCISSAS and weights can be computed analytically for small  $n$ .

$n$	$x_i$
2	$\pm \frac{1}{3}\sqrt{3}$
3	0 $\pm \frac{1}{2}\sqrt{2}$
4	$\pm \sqrt{\frac{\sqrt{5}-2}{3\sqrt{5}}}$ $\pm \sqrt{\frac{\sqrt{5}+2}{3\sqrt{5}}}$
5	0 $\pm \frac{1}{2}\sqrt{\frac{5-\sqrt{11}}{3}}$ $\pm \frac{1}{2}\sqrt{\frac{5+\sqrt{11}}{3}}$

### Chebyshev Sum Inequality

If

$$a_1 \geq a_2 \geq \dots \geq a_n$$

$$b_1 \geq b_2 \geq \dots \geq b_n,$$

then

$$n \sum_{k=1}^n a_k b_k \geq \left( \sum_{k=1}^n a_k \right) \left( \sum_{k=1}^n b_k \right).$$

This is true for any distribution.

### Chebyshev-Sylvester Constant

In 1891, Chebyshev and Sylvester showed that for sufficiently large  $x$ , there exists at least one prime number  $p$  satisfying

$$x < p < (1 + \alpha)x,$$

where  $\alpha = 0.092\dots$ . Since the PRIME NUMBER THEOREM shows the above inequality is true for all  $\alpha > 0$  for sufficiently large  $x$ , this constant is only of historical interest.

**Checker-Jumping Problem**

Seeks the minimum number of checkers placed on a board required to allow pieces to move by a sequence of horizontal or vertical jumps (removing the piece jumped over)  $n$  rows beyond the forward-most initial checker. The first few cases are 2, 4, 8, 20. It is, however, impossible to reach level 5.

**Checkers**

Beeler *et al.* (1972, Item 93) estimated that there are about  $10^{12}$  possible positions. However, this disagrees with the estimate of Jon Schaeffer of  $5 \times 10^{20}$  plausible positions, with  $10^{18}$  reachable under the rules of the game. Because “solving” checkers may require only the SQUARE ROOT of the number of positions in the search space (i.e.,  $10^9$ ), so there is hope that some day checkers may be solved (i.e., it may be possible to guarantee a win for the first player to move before the game is even started; Dubuque 1996).

Depending on how they are counted, the number of EULERIAN CIRCUITS on an  $n \times n$  checkerboard are either 1, 40, 793, 12800, 193721, ... (Sloane's A006240) or 1, 13, 108, 793, 5611, 39312, ... (Sloane's A006239).

**Checksum**

A sum of the digits in a given transmission modulo some number. The simplest form of checksum is a parity bit appended on to 7-bit numbers (e.g., ASCII characters) such that the total number of 1s is always EVEN (“even parity”) or ODD (“odd parity”). A significantly more sophisticated checksum is the CYCLIC REDUNDANCY CHECK (or CRC), which is based on the algebra of polynomials over the integers (mod 2). It is substantially more reliable in detecting transmission errors, and is one common error-checking protocol used in modems.

**Chern Class**

A GADGET defined for COMPLEX VECTOR BUNDLES. The Chern classes of a COMPLEX MANIFOLD are the Chern classes of its TANGENT BUNDLE. The  $i$ th Chern class is an OBSTRUCTION to the existence of  $(n - i + 1)$  everywhere COMPLEX linearly independent VECTOR FIELDS on that VECTOR BUNDLE. The  $i$ th Chern class is in the  $(2i)$ th cohomology group of the base SPACE.

see also OBSTRUCTION, PONTRYAGIN CLASS, STIEFEL-WHITNEY CLASS

**Chern Number**

The Chern number is defined in terms of the CHERN CLASS of a MANIFOLD as follows. For any collection CHERN CLASSES such that their cup product has the same DIMENSION as the MANIFOLD, this cup product can be evaluated on the MANIFOLD's FUNDAMENTAL CLASS. The resulting number is called the Chern number for that combination of Chern classes. The most important aspect of Chern numbers is that they are COBORDISM invariant.

see also PONTRYAGIN NUMBER, STIEFEL-WHITNEY NUMBER

### Chernoff Face

A way to display  $n$  variables on a 2-D surface. For instance, let  $x$  be eyebrow slant,  $y$  be eye size,  $z$  be nose length, etc.

### Chess

Chess is a game played on an  $8 \times 8$  board, called a CHESSBOARD, of alternating black and white squares. Pieces with different types of allowed moves are placed on the board, a set of black pieces in the first two rows and a set of white pieces in the last two rows. The pieces are called the bishop (2), king (1), knight (2), pawn (8), queen (1), and rook (2). The object of the game is to capture the opponent's king. It is believed that chess was played in India as early as the sixth century AD.

In a game of 40 moves, the number of possible board positions is at least  $10^{120}$  according to Peterson (1996). However, this value does not agree with the  $10^{40}$  possible positions given by Beeler *et al.* (1972, Item 95). This value was obtained by estimating the number of pawn positions (in the no-captures situation, this is  $15^8$ ), times all pieces in all positions, dividing by 2 for each of the (rook, knight) which are interchangeable, dividing by 2 for each pair of bishops (since half the positions will have the bishops on the same color squares). There are more positions with one or two captures, since the pawns can then switch columns (Schroeppel 1996). Shannon (1950) gave the value

$$P(40) \approx \frac{64!}{32!(8!)^2(2!)^6} \approx 10^{43}.$$

The number of chess games which end in exactly  $n$  plies (including games that mate in fewer than  $n$  plies) for  $n = 1, 2, 3, \dots$  are 20, 400, 8902, 197742, 4897256, 119060679, 3195913043, ... (K. Thompson, Sloane's A007545). Rex Stout's fictional detective Nero Wolfe quotes the number of possible games after ten moves as follows: "Wolfe grunted. One hundred and sixty-nine million, five hundred and eighteen thousand, eight hundred and twenty-nine followed by twenty-one ciphers. The number of ways the first ten moves, both sides, may be played" (Stout 1983). The number of chess positions after  $n$  moves for  $n = 1, 2, \dots$  are 20, 400, 5362, 71852, 809896?, 9132484?, ... (Schwarzkopf 1994, Sloane's A019319).

Cunningham (1889) incorrectly found 197,299 games and 71,782 positions after the fourth move. C. Flye St. Marie was the first to find the correct number of positions after four moves: 71,852. Dawson (1946) gives the source as *Intermediare des Mathematiques* (1895), but K. Fabel writes that Flye St. Marie corrected the number 71,870 (which he found in 1895) to 71,852 in

1903. The history of the determination of the chess sequences is discussed in Schwarzkopf (1994).

Two problems in recreational mathematics ask

1. How many pieces of a given type can be placed on a CHESSBOARD without any two attacking.
2. What is the smallest number of pieces needed to occupy or attack every square.

The answers are given in the following table (Madachy 1979).

Piece	Max.	Min.
bishops	14	8
kings	16	9
knight	32	12
queens	8	5
rooks	8	8

## Chessboard

A board containing  $8 \times 8$  squares alternating in color between black and white on which the game of CHESS is played. The checkerboard is identical to the chessboard except that chess's black and white squares are colored red and white in CHECKERS. It is impossible to cover a chessboard from which two opposite corners have been removed with DOMINOES.

## Chi Distribution

The probability density function and cumulative distribution function are

$$P_n(x) = \frac{2^{1-n/2} x^{n-1} e^{-x^2/2}}{\Gamma(\frac{1}{2}n)} \quad (1)$$

$$D_n(x) = Q(\frac{1}{2}n, \frac{1}{2}x^2), \quad (2)$$

where  $Q$  is the REGULARIZED GAMMA FUNCTION.

$$\mu = \frac{\sqrt{2}\Gamma(\frac{1}{2}(n+1))}{\Gamma(\frac{1}{2}n)} \quad (3)$$

$$\sigma^2 = \frac{2[\Gamma(\frac{1}{2}n)\Gamma(1+\frac{1}{2}n) - \Gamma^2(\frac{1}{2}(n+1))]}{\Gamma^2(\frac{1}{2}n)} \quad (4)$$

$$\gamma_1 = \frac{2\Gamma^3(\frac{1}{2}(n+1)) - 3\Gamma(\frac{1}{2}n)\Gamma(\frac{1}{2}(n+1))\Gamma(1+\frac{1}{2}n)}{[\Gamma(\frac{1}{2}n)\Gamma(1+\frac{1}{2}n) - \Gamma^2(\frac{1}{2}(n+1))]^{3/2}}$$

$$\begin{aligned}
& + \frac{\Gamma^2(\frac{1}{2}n)\Gamma(\frac{3+n}{2})}{[\Gamma(\frac{1}{2}n)\Gamma(1+\frac{1}{2}n) - \Gamma^2(\frac{1}{2}(n+1))]^{3/2}} \quad (5) \\
\gamma_2 = & \frac{-3\Gamma^4(\frac{1}{2}(n+1)) + 6\Gamma(\frac{1}{2}n) + \Gamma^2(\frac{1}{2}(n+1))\Gamma(1+\frac{1}{2}n)}{[\Gamma(\frac{1}{2}n)\Gamma(\frac{2+n}{2}) - \Gamma^2(\frac{1}{2}(n+1))]^2} \\
& + \frac{-4\Gamma^2(\frac{1}{2}n)\Gamma(\frac{1}{2}(n+1))\Gamma(\frac{3+n}{2}) + \Gamma^3(\frac{1}{2}n)\Gamma(\frac{4+n}{2})}{[\Gamma(\frac{1}{2}n)\Gamma(\frac{2+n}{2}) - \Gamma^2(\frac{1}{2}(n+1))]^2}, \quad (6)
\end{aligned}$$

where  $\mu$  is the MEAN,  $\sigma^2$  the VARIANCE,  $\gamma_1$  the SKEWNESS, and  $\gamma_2$  the KURTOSIS. For  $n = 1$ , the  $\chi$  distribution is a HALF-NORMAL DISTRIBUTION with  $\theta = 1$ . For  $n = 2$ , it is a RAYLEIGH DISTRIBUTION with  $\sigma = 1$ .

see also CHI-SQUARED DISTRIBUTION, HALF-NORMAL DISTRIBUTION, RAYLEIGH DISTRIBUTION

### Chi Inequality

The inequality

$$(j+1)a_j + a_i \geq (j+1)i,$$

which is satisfied by all *A*-SEQUENCES.

### References

Levine, E. and O'Sullivan, J. "An Upper Estimate for the Reciprocal Sum of a Sum-Free Sequence." *Acta Arith.* **34**, 9-24, 1977.

### Chi-Squared Distribution

A  $\chi^2$  distribution is a GAMMA DISTRIBUTION with  $\theta \equiv 2$  and  $\alpha \equiv r/2$ , where  $r$  is the number of DEGREES OF FREEDOM. If  $Y_i$  have NORMAL INDEPENDENT distributions with MEAN 0 and VARIANCE 1, then

$$\chi^2 \equiv \sum_{i=1}^n Y_i^2 \quad (1)$$

is distributed as  $\chi^2$  with  $n$  DEGREES OF FREEDOM. If  $\chi_i^2$  are independently distributed according to a  $\chi^2$  distribution with  $n_1, n_2, \dots, n_k$  DEGREES OF FREEDOM, then

$$\sum_{j=1}^k \chi_j^2 \quad (2)$$

is distributed according to  $\chi^2$  with  $n \equiv \sum_{j=1}^n n_j$  DEGREES OF FREEDOM.

$$P_n(x) = \begin{cases} \frac{x^{r/2-1}e^{-x/2}}{\Gamma(\frac{1}{2}r)2^{r/2}} & \text{for } 0 \leq x < \infty \\ 0 & \text{for } x < 0. \end{cases} \quad (3)$$

The cumulative distribution function is then

$$\begin{aligned}
D_n(\chi^2) &= \int_0^{\chi^2} \frac{t^{r/2-1}e^{-t/2} dt}{\Gamma(\frac{1}{2}r)2^{r/2}} \\
&= \frac{\gamma(\frac{1}{2}n, \frac{1}{2}\chi^2)}{\Gamma(\frac{1}{2}n)} = P(\frac{1}{2}n, \frac{1}{2}\chi^2), \quad (4)
\end{aligned}$$

where  $P(a, z)$  is a REGULARIZED GAMMA FUNCTION. The CONFIDENCE INTERVALS can be found by finding the value of  $x$  for which  $D_n(x)$  equals a given value. The MOMENT-GENERATING FUNCTION of the  $\chi^2$  distribution is

$$M(t) = (1 - 2t)^{-r/2} \quad (5)$$

$$R(t) \equiv \ln M(t) = -\frac{1}{2}r \ln(1 - 2t) \quad (6)$$

$$R'(t) = \frac{r}{1 - 2t} \quad (7)$$

$$R''(t) = \frac{2r}{(1 - 2t)^2}, \quad (8)$$

so

$$\mu = R'(0) = r \quad (9)$$

$$\sigma^2 = R''(0) = 2r \quad (10)$$

$$\gamma_1 = 2\sqrt{\frac{2}{r}} \quad (11)$$

$$\gamma_2 = \frac{12}{r}. \quad (12)$$

The  $n$ th MOMENT about zero for a distribution with  $n$  DEGREES OF FREEDOM is

$$m'_n = 2^n \frac{\Gamma(n + \frac{1}{2}r)}{\Gamma(\frac{1}{2}r)} = r(r+2) \cdots (r+2n-2), \quad (13)$$

and the moments about the MEAN are

$$\mu_2 = 2r \quad (14)$$

$$\mu_3 = 8r \quad (15)$$

$$\mu_4 = 12n^2 + 48n. \quad (16)$$

The  $n$ th CUMULANT is

$$\kappa_n = 2^n \Gamma(n)(\frac{1}{2}r) = 2^{n-1}(n-1)!r. \quad (17)$$

The MOMENT-GENERATING FUNCTION is

$$\begin{aligned}
M(t) &= e^{rt/\sqrt{2r}} \left(1 - \frac{2t}{\sqrt{2r}}\right)^{-r/2} \\
&= \left[ e^{t\sqrt{2/r}} \left(1 - \sqrt{\frac{2}{r}}t\right) \right]^{-r/2} \\
&= \left[ 1 - \frac{t^2}{r} - \frac{1}{3} \left(\frac{2}{r}\right)^{3/2} t^3 - \dots \right]^{-r/2}. \quad (18)
\end{aligned}$$

As  $r \rightarrow \infty$ ,

$$\lim_{r \rightarrow \infty} M(t) = e^{t^2/2}, \quad (19)$$

so for large  $r$ ,

$$\sqrt{2\chi^2} = \sqrt{\sum_i \frac{(x_i - \mu_i)^2}{\sigma_i^2}} \quad (20)$$

is approximately a GAUSSIAN DISTRIBUTION with MEAN  $\sqrt{2r}$  and VARIANCE  $\sigma^2 = 1$ . Fisher showed that

$$\frac{\chi^2 - r}{\sqrt{2r - 1}} \quad (21)$$

is an improved estimate for moderate  $r$ . Wilson and Hilferty showed that

$$\left(\frac{\chi^2}{r}\right)^{1/3} \quad (22)$$

is a nearly GAUSSIAN DISTRIBUTION with MEAN  $\mu = 1 - 2/(9r)$  and VARIANCE  $\sigma^2 = 2/(9r)$ .

In a GAUSSIAN DISTRIBUTION,

$$P(x) dx = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/2\sigma^2} dx, \quad (23)$$

let

$$z \equiv (x - \mu)^2 / \sigma^2. \quad (24)$$

Then

$$dz = \frac{2(x - \mu)}{\sigma^2} dx = \frac{2\sqrt{z}}{\sigma} dx \quad (25)$$

so

$$dx = \frac{\sigma}{2\sqrt{z}} dz. \quad (26)$$

But

$$P(z) dz = 2P(x) dx, \quad (27)$$

so

$$P(x) dx = 2 \frac{1}{\sigma\sqrt{2\pi}} e^{-z/2} dz = \frac{1}{\sigma\sqrt{\pi}} e^{-z/2} dz. \quad (28)$$

This is a  $\chi^2$  distribution with  $r = 1$ , since

$$P(z) dz = \frac{z^{1/2-1} e^{-z/2}}{\Gamma(\frac{1}{2})2^{1/2}} dz = \frac{x^{-1/2} e^{-1/2}}{\sqrt{2\pi}} dz. \quad (29)$$

If  $X_i$  are independent variates with a NORMAL DISTRIBUTION having MEANS  $\mu_i$  and VARIANCES  $\sigma_i^2$  for  $i = 1, \dots, n$ , then

$$\frac{1}{2}\chi^2 \equiv \sum_{i=1}^n \frac{(x_i - \mu_i)^2}{2\sigma_i^2} \quad (30)$$

is a GAMMA DISTRIBUTION variate with  $\alpha = n/2$ ,

$$P(\frac{1}{2}\chi^2) d(\frac{1}{2}\chi^2) = \frac{1}{\Gamma(\frac{1}{2}n)} e^{-\chi^2/2} (\frac{1}{2}\chi^2)^{(n/2)-1} d(\frac{1}{2}\chi^2). \quad (31)$$

The noncentral chi-squared distribution is given by

$$P(x) = 2^{-n/2} e^{-(\lambda+x)/2} x^{n/2-1} F(\frac{1}{2}n, \frac{1}{4}\lambda x), \quad (32)$$

where

$$F(a, z) \equiv \frac{{}_0F_1(; a; z)}{\Gamma(a)}, \quad (33)$$

${}_0F_1$  is the CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION and  $\Gamma$  is the GAMMA FUNCTION. The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \lambda + n \quad (34)$$

$$\sigma^2 = 2(2\lambda + n) \quad (35)$$

$$\gamma_1 = \frac{2\sqrt{2}(3\lambda + n)}{(2\lambda + n)^{3/2}} \quad (36)$$

$$\gamma_2 = \frac{12(4\lambda + n)}{(2\lambda + n)^2}. \quad (37)$$

### Chi-Squared Test

Let the probabilities of various classes in a distribution be  $p_1, p_2, \dots, p_k$ . The expected frequency

$$\chi_s^2 = \sum_{i=1}^k \frac{(m_i - Np_i)^2}{Np_i}$$

is a measure of the deviation of a sample from expectation. Karl Pearson proved that the limiting distribution of  $\chi_s^2$  is  $\chi^2$  (Kenney and Keeping 1951, pp. 114-116).

$$\begin{aligned} \Pr(\chi^2 \geq \chi_s^2) &= \int_{\chi_s^2}^{\infty} f(\chi^2) d(\chi^2) \\ &= \frac{1}{2} \int_{\chi_s^2}^{\infty} \frac{\left(\frac{\chi^2}{2}\right)^{(k-3)/2}}{\Gamma\left(\frac{k-1}{2}\right)} e^{-\chi^2/2} d(\chi^2) \\ &= 1 - \frac{\Gamma\left(\frac{1}{2}\chi_s^2, \frac{k-1}{2}\right)}{\Gamma\left(\frac{k-1}{2}\right)} \\ &= 1 - I\left(\frac{\chi_s^2}{\sqrt{2(k-1)}}, \frac{k-3}{2}\right), \end{aligned}$$

where  $I(x, n)$  is PEARSON'S FUNCTION. There are some subtleties involved in using the  $\chi^2$  test to fit curves (Kenney and Keeping 1951, pp. 118-119).

When fitting a one-parameter solution using  $\chi^2$ , the best-fit parameter value can be found by calculating  $\chi^2$

at three points, plotting against the parameter values of these points, then finding the minimum of a PARABOLA fit through the points (Cuzzi 1972, pp. 162–168).

### Chinese Hypothesis

A PRIME  $p$  always satisfies the condition that  $2^p - 2$  is divisible by  $p$ . However, this condition is not true *exclusively* for PRIME (e.g.,  $2^{341} - 2$  is divisible by  $341 = 11 \cdot 31$ ). COMPOSITE NUMBERS  $n$  (such as 341) for which  $2^n - 2$  is divisible by  $n$  are called POULET NUMBERS, and are a special class of FERMAT PSEUDOPRIMES. The Chinese hypothesis is a special case of FERMAT'S LITTLE THEOREM.

### Chinese Remainder Theorem

Let  $r$  and  $s$  be POSITIVE INTEGERS which are RELATIVELY PRIME and let  $a$  and  $b$  be any two INTEGERS. Then there is an INTEGER  $N$  such that

$$N \equiv a \pmod{r} \quad (1)$$

and

$$N \equiv b \pmod{s}. \quad (2)$$

Moreover,  $N$  is uniquely determined modulo  $rs$ . An equivalent statement is that if  $(r, s) = 1$ , then every pair of RESIDUE CLASSES modulo  $r$  and  $s$  corresponds to a simple RESIDUE CLASS modulo  $rs$ .

The theorem can also be generalized as follows. Given a set of simultaneous CONGRUENCES

$$x \equiv a_i \pmod{m_i} \quad (3)$$

for  $i = 1, \dots, r$  and for which the  $m_i$  are pairwise RELATIVELY PRIME, the solution of the set of CONGRUENCES is

$$x = a_1 b_1 \frac{M}{m_1} + \dots + a_r b_r \frac{M}{m_r} \pmod{M}, \quad (4)$$

where

$$M \equiv m_1 m_2 \cdots m_r \quad (5)$$

and the  $b_i$  are determined from

$$b_i \frac{M}{m_i} \equiv 1 \pmod{m_i}. \quad (6)$$

### Choose

An alternative term for a BINOMIAL COEFFICIENT, in which  $\binom{n}{k}$  is read as " $n$  choose  $k$ ." R. K. Guy suggested this pronunciation around 1950, when the notations  ${}^nC_r$  and  ${}_nC_r$  were commonly used. Leo Moser liked the pronunciation and he and others spread it around. It got the final seal of approval from Donald Knuth when he incorporated it into the TeX mathematical typesetting language as `{n\choose k}`.

### Choquet Theory

Erdős proved that there exist at least one PRIME of the form  $4k + 1$  and at least one PRIME of the form  $4k + 3$  between  $n$  and  $2n$  for all  $n > 6$ .

see also EQUINUMEROUS, PRIME NUMBER

### Chord

The LINE SEGMENT joining two points on a curve. The term is often used to describe a LINE SEGMENT whose ends lie on a CIRCLE. In the above figure,  $r$  is the RADIUS of the CIRCLE,  $a$  is called the APOTHEM, and  $s$  the SAGITTA.

The shaded region in the left figure is called a SECTOR, and the shaded region in the right figure is called a SEGMENT.

All ANGLES inscribed in a CIRCLE and subtended by the same chord are equal. The converse is also true: The LOCUS of all points from which a given segment subtends equal ANGLES is a CIRCLE.

Let a CIRCLE of RADIUS  $R$  have a CHORD at distance  $r$ . The AREA enclosed by the CHORD, shown as the shaded region in the above figure, is then

$$A = 2 \int_0^{\sqrt{R^2 - r^2}} x(y) dy. \quad (1)$$

But

$$y^2 + (r + x)^2 = R^2, \quad (2)$$

so

$$x(y) = \sqrt{R^2 - y^2} - r \quad (3)$$

and

$$\begin{aligned} A &= 2 \int_0^{\sqrt{R^2 - r^2}} (\sqrt{R^2 - y^2} - r) dy \\ &= \left[ y\sqrt{R^2 - y^2} + R^2 \tan^{-1} \left( \frac{y}{\sqrt{R^2 - y^2}} \right) - 2ry \right]_0^{\sqrt{R^2 - r^2}} \\ &= r\sqrt{R^2 - r^2} + R^2 \tan^{-1} \left[ \left( \frac{R}{r} \right)^2 - 1 \right] - 2r\sqrt{R^2 - r^2} \\ &= R^2 \tan^{-1} \left[ \left( \frac{R}{r} \right)^2 - 1 \right] - r\sqrt{R^2 - r^2}. \end{aligned} \quad (4)$$

Checking the limits, when  $r = R$ ,  $A = 0$  and when  $r \rightarrow 0$ ,

$$A = \frac{1}{2} \pi R^2, \quad (5)$$

see also ANNULUS, APOTHEM, BERTRAND'S PROBLEM, CONCENTRIC CIRCLES, RADIUS, SAGITTA, SECTOR, SEGMENT

### Chordal

see RADICAL AXIS

### Chordal Theorem

The LOCUS of the point at which two given CIRCLES possess the same POWER is a straight line PERPENDICULAR to the line joining the MIDPOINTS of the CIRCLE and is known as the chordal (or RADICAL AXIS) of the two CIRCLES.

### Chow Coordinates

A generalization of GRASSMANN COORDINATES to  $m$ -D varieties of degree  $d$  in  $P^n$ , where  $P^n$  is an  $n$ -D projective space. To define the Chow coordinates, take the intersection of a  $m$ -D VARIETY  $Z$  of degree  $d$  by an  $(n - m)$ -D SUBSPACE  $U$  of  $P^n$ . Then the coordinates of the  $d$  points of intersection are algebraic functions of the GRASSMANN COORDINATES of  $U$ , and by taking a symmetric function of the algebraic functions, a hHOMOGENEOUS POLYNOMIAL known as the Chow form of  $Z$  is obtained. The Chow coordinates are then

the COEFFICIENTS of the Chow form. Chow coordinates can generate the smallest field of definition of a divisor.

#### Christoffel-Darboux Formula

For three consecutive ORTHOGONAL POLYNOMIALS

$$p_n(x) = (A_n x + B_n)p_{n-1}(x) - C_n p_{n-2}(x) \quad (1)$$

for  $n = 2, 3, \dots$ , where  $A_n > 0$ ,  $B_n$ , and  $C_n > 0$  are constants. Denoting the highest COEFFICIENT of  $p_n(x)$  by  $k_n$ ,

$$A_n = \frac{k_n}{k_{n-1}} \quad (2)$$

$$C_n = \frac{A_n}{A_{n-1}} = \frac{k_n k_{n-2}}{k_{n-1}^2}. \quad (3)$$

Then

$$\begin{aligned} p_0(x)p_0(y) + \dots + p_n(x)p_n(y) \\ = \frac{k_n}{k_{n+1}} \frac{p_{n+1}(x)p_n(y) - p_n(x)p_{n+1}(y)}{x - y}. \end{aligned} \quad (4)$$

In the special case of  $x = y$ , (4) gives

$$\begin{aligned} [p_0(x)]^2 + \dots + [p_n(x)]^2 \\ = \frac{k_n}{k_{n+1}} [p'_{n+1}(x)p_n(x) - p'_n(x)p_{n+1}(x)]. \end{aligned} \quad (5)$$

#### References

#### Christoffel-Darboux Identity

$$\sum_{k=0}^{\infty} \frac{\phi_k(x)\phi_k(y)}{\gamma_k} = \frac{\phi_{m+1}(x)\phi_m(y) - \phi_m(x)\phi_{m+1}(y)}{a_m \gamma_m (x - y)}, \quad (1)$$

where  $\phi_k(x)$  are ORTHOGONAL POLYNOMIALS with WEIGHTING FUNCTION  $W(x)$ ,

$$\gamma_m \equiv \int [\phi_m(x)]^2 W(x) dx, \quad (2)$$

and

$$a_k \equiv \frac{A_{k+1}}{A_k} \quad (3)$$

where  $A_k$  is the COEFFICIENT of  $x^k$  in  $\phi_k(x)$ .

#### References

- Hildebrand, F. B. *Introduction to Numerical Analysis*. New York: McGraw-Hill, p. 322, 1956.

#### Christoffel Formula

Let  $\{p_n(x)\}$  be orthogonal POLYNOMIALS associated with the distribution  $d\alpha(x)$  on the interval  $[a, b]$ . Also let

$$\rho \equiv c(x - x_1)(x - x_2) \cdots (x - x_l)$$

(for  $c \neq 0$ ) be a POLYNOMIAL of order  $l$  which is NONNEGATIVE in this interval. Then the orthogonal POLYNOMIALS  $\{q(x)\}$  associated with the distribution  $\rho(x) d\alpha(x)$  can be represented in terms of the POLYNOMIALS  $p_n(x)$  as

$$\rho(x)q_n(x) = \begin{vmatrix} p_n(x) & p_{n+1}(x) & \cdots & p_{n+l}(x) \\ p_n(x_1) & p_{n+1}(x_1) & \cdots & p_{n+l}(x_1) \\ \vdots & \vdots & \ddots & \vdots \\ p_n(x_l) & p_{n+1}(x_l) & \cdots & p_{n+l}(x_l) \end{vmatrix}.$$

In the case of a zero  $x_k$  of multiplicity  $m > 1$ , we replace the corresponding rows by the derivatives of order 0, 1, 2,  $\dots$ ,  $m - 1$  of the POLYNOMIALS  $p_n(x_1), \dots, p_{n+l}(x_l)$  at  $x = x_k$ .

#### Christoffel Number

One of the quantities  $\lambda_i$  appearing in the GAUSS-JACOBI MECHANICAL QUADRATURE. They satisfy

$$\lambda_1 + \lambda_2 + \dots + \lambda_n = \int_a^b d\alpha(x) = \alpha(b) - \alpha(a) \quad (1)$$

and are given by

$$\lambda_\nu = \int_a^b \left[ \frac{p_n(x)}{p'_n(x_\nu)(x - x_\nu)} \right]^2 d\alpha(x) \quad (2)$$

$$\lambda_\nu = -\frac{k_{n+1}}{k_n} \frac{1}{p_{n+1}(x_\nu)p'_n(x_\nu)} \quad (3)$$

$$= \frac{k_n}{k_{n-1}} \frac{1}{p_{n-1}(x_\nu)P'_n(x_\nu)} \quad (4)$$

$$(\lambda_\nu)^{-1} = [p_0(x_\nu)]^2 + \dots + [p_n(x_\nu)]^2, \quad (5)$$

where  $k_n$  is the higher COEFFICIENT of  $p_n(x)$ .

#### References

Szegő, G. *Orthogonal Polynomials*, 4th ed. Providence, RI: Amer. Math. Soc., pp. 47–48, 1975.

#### Christoffel Symbol of the First Kind

Variously denoted  $[ij, k]$ ,  $\begin{bmatrix} i & j \\ k \end{bmatrix}$ ,  $\Gamma_{abc}$ , or  $\{ab, c\}$ .

$$[ij, k] = \begin{bmatrix} i & j \\ k \end{bmatrix} \equiv g_{mk} \Gamma_{ij}^m = g_{mk} \vec{e}^m \cdot \frac{\partial \vec{e}_i}{\partial q^j} = \vec{e}_k \cdot \frac{\partial \vec{e}_i}{\partial q^j}, \quad (1)$$

where  $g_{mk}$  is the METRIC TENSOR and

$$\vec{e}_i \equiv \frac{\partial \vec{r}}{\partial q^i} = h_i \hat{e}_i. \quad (2)$$

But

$$\begin{aligned} \frac{\partial g_{ij}}{\partial q^k} &= \frac{\partial}{\partial q^k} (\vec{e}_i \cdot \vec{e}_j) = \frac{\partial \vec{e}_i}{\partial q^k} \cdot \vec{e}_j + \vec{e}_i \cdot \frac{\partial \vec{e}_j}{\partial q^k} \\ &= [ik, j] + [jk, i], \end{aligned} \quad (3)$$

so

$$[ab, c] = \frac{1}{2}(g_{ac,b} + g_{bc,a} - g_{ab,c}). \quad (4)$$

#### References

Arfken, G. *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 160–167, 1985.

#### Christoffel Symbol of the Second Kind

Variously denoted  $\begin{Bmatrix} m \\ i & j \end{Bmatrix}$  or  $\Gamma_{ij}^m$ .

$$\begin{aligned} \begin{Bmatrix} m \\ i & j \end{Bmatrix} &\equiv \Gamma_{ij}^m = \vec{e}^m \cdot \frac{\partial \vec{e}_i}{\partial q^j} = g^{km} [ij, k] \\ &= \frac{1}{2} g^{km} \left( \frac{\partial g_{ik}}{\partial q^j} + \frac{\partial g_{jk}}{\partial q^i} - \frac{\partial g_{ij}}{\partial q^k} \right), \end{aligned} \quad (1)$$

where  $\Gamma_{ij}^m$  is a CONNECTION COEFFICIENT and  $\{bc, d\}$  is a CHRISTOFFEL SYMBOL OF THE FIRST KIND.

$$\begin{Bmatrix} a \\ b & c \end{Bmatrix} = g_{ad} \{bc, d\}. \quad (2)$$

The Christoffel symbols are given in terms of the first FUNDAMENTAL FORM  $E$ ,  $F$ , and  $G$  by

$$\Gamma_{11}^1 = \frac{GE_u - 2FF_u + FE_v}{2(EG - F^2)} \quad (3)$$

$$\Gamma_{12}^1 = \frac{GE_v - FG_u}{2(EG - F^2)} \quad (4)$$

$$\Gamma_{22}^1 = \frac{2GF_v - GG_u - FG_v}{2(EG - F^2)} \quad (5)$$

$$\Gamma_{11}^2 = \frac{2EF_u - EE_v - FE_u}{2(EG - F^2)} \quad (6)$$

$$\Gamma_{12}^2 = \frac{EG_u - FE_v}{2(EG - F^2)} \quad (7)$$

$$\Gamma_{22}^2 = \frac{EG_v - 2FF_v + FG_u}{2(EG - F^2)}, \quad (8)$$

and  $\Gamma_{21}^1 = \Gamma_{12}^1$  and  $\Gamma_{21}^2 = \Gamma_{12}^2$ . If  $F = 0$ , the Christoffel symbols of the second kind simplify to

$$\Gamma_{11}^1 = \frac{E_u}{2E} \quad (9)$$

$$\Gamma_{12}^1 = \frac{E_v}{2E} \quad (10)$$

$$\Gamma_{22}^1 = -\frac{G_u}{2E} \quad (11)$$

$$\Gamma_{11}^2 = -\frac{E_v}{2G} \quad (12)$$

$$\Gamma_{12}^2 = \frac{G_u}{2G} \quad (13)$$

$$\Gamma_{22}^2 = \frac{G_v}{2G} \quad (14)$$

(Gray 1993).

The following relationships hold between the Christoffel symbols of the second kind and coefficients of the first FUNDAMENTAL FORM,

$$\Gamma_{11}^1 E + \Gamma_{11}^2 F = \frac{1}{2} E_u \quad (15)$$

$$\Gamma_{12}^1 E + \Gamma_{12}^2 F = \frac{1}{2} E_v \quad (16)$$

$$\Gamma_{22}^1 E + \Gamma_{22}^2 F = F_v - \frac{1}{2} G_u \quad (17)$$

$$\Gamma_{11}^1 F + \Gamma_{11}^2 G = F_u - \frac{1}{2} E_v \quad (18)$$

$$\Gamma_{12}^1 F + \Gamma_{12}^2 G = \frac{1}{2} G_u \quad (19)$$

$$\Gamma_{22}^1 F + \Gamma_{22}^2 G = \frac{1}{2} G_v \quad (20)$$

$$\Gamma_{11}^1 + \Gamma_{12}^2 = (\ln \sqrt{EG - F^2})_u \quad (21)$$

$$\Gamma_{12}^1 + \Gamma_{22}^2 = (\ln \sqrt{EG - F^2})_v \quad (22)$$

(Gray 1993).

For a surface given in MONGE'S FORM  $z = F(x, y)$ ,

$$\Gamma_{ij}^k = \frac{z_{ij} z_k}{1 + z_1^2 + z_2^2}. \quad (23)$$

## Chromatic Number

The fewest number of colors  $\gamma(G)$  necessary to color a GRAPH or surface. The chromatic number of a surface of GENUS  $g$  is given by the HEAWOOD CONJECTURE,

$$\gamma(g) = \left\lfloor \frac{1}{2}(7 + \sqrt{48g + 1}) \right\rfloor,$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION.  $\gamma(g)$  is sometimes also denoted  $\chi(g)$ . For  $g = 0, 1, \dots$ , the first few values of  $\chi(g)$  are 4, 7, 8, 9, 10, 11, 12, 12, 13, 13, 14, 15, 15, 16, ... (Sloane's A000934).

The fewest number of colors necessary to color each EDGE of a GRAPH so that no two EDGES incident on the same VERTEX have the same color is called the “EDGE chromatic number.”

## Chromatic Polynomial

A POLYNOMIAL  $P(z)$  of a graph  $g$  which counts the number of ways to color  $g$  with exactly  $z$  colors. Tutte (1970) showed that the chromatic POLYNOMIALS of planar triangular graphs possess a ROOT close to  $\phi^2 = 2.618033\dots$ , where  $\phi$  is the GOLDEN MEAN. More precisely, if  $n$  is the number of VERTICES of  $G$ , then

$$P_G(\phi^2) \leq \phi^{5-n}$$

(Le Lionnais 1983).

## Circle

A circle is the set of points equidistant from a given point  $O$ . The distance  $r$  from the CENTER is called the RADIUS, and the point  $O$  is called the CENTER. Twice the RADIUS is known as the DIAMETER  $d = 2r$ . The PERIMETER  $C$  of a circle is called the CIRCUMFERENCE, and is given by

$$C = \pi d = 2\pi r. \quad (1)$$

The circle is a CONIC SECTION obtained by the intersection of a CONE with a PLANE PERPENDICULAR to the CONE's symmetry axis. A circle is the degenerate case of an ELLIPSE with equal semimajor and semiminor axes (i.e., with ECCENTRICITY 0). The interior of a circle is called a DISK. The generalization of a circle to 3-D is called a SPHERE, and to  $n$ -D for  $n \geq 4$  a HYPERSPHERE.

The region of intersection of two circles is called a LENS. The region of intersection of three symmetrically placed circles (as in a VENN DIAGRAM), in the special case of the center of each being located at the intersection of the other two, is called a REULEAUX TRIANGLE.

The parametric equations for a circle of RADIUS  $a$  are

$$x = a \cos t \quad (2)$$

$$y = a \sin t. \quad (3)$$

For a body moving uniformly around the circle,

$$x' = -a \sin t \quad (4)$$

$$y' = a \cos t, \quad (5)$$

and

$$x'' = -a \cos t \quad (6)$$

$$y'' = -a \sin t. \quad (7)$$

When normalized, the former gives the equation for the unit TANGENT VECTOR of the circle,  $(-\sin t, \cos t)$ . The circle can also be parameterized by the rational functions

$$x = \frac{1-t^2}{t(1+t)} \quad (8)$$

$$y = \frac{2t}{1+t^2}, \quad (9)$$

but an ELLIPTIC CURVE cannot. The following plots show a sequence of NORMAL and TANGENT VECTORS for the circle.

The ARC LENGTH  $s$ , CURVATURE  $\kappa$ , and TANGENTIAL ANGLE  $\phi$  of the circle are

$$s(t) = \int ds = \int \sqrt{x'^2 + y'^2} dt = at \quad (10)$$

$$\kappa(t) = \frac{x'y'' - y'x''}{(x'^2 + y'^2)^{3/2}} = \frac{1}{a} \quad (11)$$

$$\phi(t) = \int \kappa(t) dt = \frac{t}{a}. \quad (12)$$

The CESÀRO EQUATION is

$$\kappa = \frac{1}{a}. \quad (13)$$

In POLAR COORDINATES, the equation of the circle has a particularly simple form.

$$r = a \quad (14)$$

is a circle of RADIUS  $a$  centered at ORIGIN,

$$r = 2a \cos \theta \quad (15)$$

is circle of RADIUS  $a$  centered at  $(a, 0)$ , and

$$r = 2a \sin \theta \quad (16)$$

is a circle of RADIUS  $a$  centered on  $(0, a)$ . In CARTESIAN COORDINATES, the equation of a circle of RADIUS  $a$  centered on  $(x_0, y_0)$  is

$$(x - x_0)^2 + (y - y_0)^2 = a^2. \quad (17)$$

In PEDAL COORDINATES with the PEDAL POINT at the center, the equation is

$$pa = r^2. \quad (18)$$

The circle having  $P_1P_2$  as a diameter is given by

$$(x - x_1)(x - x_2) + (y - y_1)(y - y_2) = 0. \quad (19)$$

The equation of a circle passing through the three points  $(x_i, y_i)$  for  $i = 1, 2, 3$  (the CIRCUMCIRCLE of the TRIANGLE determined by the points) is

$$\begin{vmatrix} x^2 + y^2 & x & y & 1 \\ x_1^2 + y_1^2 & x_1 & y_1 & 1 \\ x_2^2 + y_2^2 & x_2 & y_2 & 1 \\ x_3^2 + y_3^2 & x_3 & y_3 & 1 \end{vmatrix} = 0. \quad (20)$$

The CENTER and RADIUS of this circle can be identified by assigning coefficients of a QUADRATIC CURVE

$$ax^2 + cy^2 + dx + ey + f = 0, \quad (21)$$

where  $a = c$  and  $b = 0$  (since there is no  $xy$  cross term). COMPLETING THE SQUARE gives

$$a \left( x + \frac{d}{2a} \right)^2 + a \left( y + \frac{e}{2a} \right)^2 + f - \frac{d^2 + e^2}{4a} = 0. \quad (22)$$

The CENTER can then be identified as

$$x_0 = -\frac{d}{2a} \quad (23)$$

$$y_0 = -\frac{e}{2a} \quad (24)$$

and the RADIUS as

$$r = \sqrt{\frac{d^2 + e^2}{4a^2} - \frac{f}{a}}, \quad (25)$$

where

$$a = \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} \quad (26)$$

$$d = - \begin{vmatrix} x_1^2 + y_1^2 & y_1 & 1 \\ x_2^2 + y_2^2 & y_2 & 1 \\ x_3^2 + y_3^2 & y_3 & 1 \end{vmatrix} \quad (27)$$

$$e = \begin{vmatrix} x_1^2 + y_1^2 & x_1 & 1 \\ x_2^2 + y_2^2 & x_2 & 1 \\ x_3^2 + y_3^2 & x_3 & 1 \end{vmatrix} \quad (28)$$

$$f = - \begin{vmatrix} x_1^2 + y_1^2 & x_1 & y_1 \\ x_2^2 + y_2^2 & x_2 & y_2 \\ x_3^2 + y_3^2 & x_3 & y_3 \end{vmatrix}. \quad (29)$$

Four or more points which lie on a circle are said to be CONCYCLIC. Three points are trivially concyclic since three noncollinear points determine a circle.

The CIRCUMFERENCE-to-DIAMETER ratio  $C/d$  for a circle is constant as the size of the circle is changed (as it must be since scaling a plane figure by a factor  $s$  increases its PERIMETER by  $s$ ), and  $d$  also scales by  $s$ . This ratio is denoted  $\pi$  (Pi), and has been proved TRANSCENDENTAL. With  $d$  the DIAMETER and  $r$  the RADIUS,

$$C = \pi d = 2\pi r. \quad (30)$$

Knowing  $C/d$ , we can then compute the AREA of the circle either geometrically or using CALCULUS. From CALCULUS,

$$A = \int_0^{2\pi} d\theta \int_0^r r dr = (2\pi) \left( \frac{1}{2} r^2 \right) = \pi r^2. \quad (31)$$

Now for a few geometrical derivations. Using concentric strips, we have

As the number of strips increases to infinity, we are left with a TRIANGLE on the right, so

$$A = \frac{1}{2} (2\pi r) r = \pi r^2. \quad (32)$$

This derivation was first recorded by Archimedes in *Measurement of a Circle* (ca. 225 BC). If we cut the circle instead into wedges,

As the number of wedges increases to infinity, we are left with a RECTANGLE, so

$$A = (\pi r) r = \pi r^2. \quad (33)$$

### Circles-and-Squares Fractal

A FRACTAL produced by iteration of the equation

$$z_{n+1} = z_n^2 \pmod{m}$$

which results in a MÛIRÉ-like pattern.

see also FRACTAL, MÛIRÉ PATTERN

### Circle Caustic

Consider a point light source located at a point  $(\mu, 0)$ . The CATACAUSTIC of a unit CIRCLE for the light at  $\mu = \infty$  is the NEPHROID

$$x = \frac{1}{4}[3 \cos t - \cos(3t)] \quad (1)$$

$$y = \frac{1}{4}[3 \sin t - \sin(3t)]. \quad (2)$$

The CATACAUSTIC for the light at a finite distance  $\mu > 1$  is the curve

$$x = \frac{\mu(1 - 3\mu \cos t + 2\mu \cos^3 t)}{-(1 + 2\mu^2) + 3\mu \cos t} \quad (3)$$

$$y = \frac{2\mu^2 \sin^3 t}{1 + 2\mu^2 - 3\mu \cos t}, \quad (4)$$

and for the light on the CIRCUMFERENCE of the CIRCLE  $\mu = 1$  is the CARDIROID

$$x = \frac{2}{3} \cos t(1 + \cos t) - \frac{1}{3} \quad (5)$$

$$y = \frac{2}{3} \sin t(1 + \cos t). \quad (6)$$

If the point is inside the circle, the catacaustic is a discontinuous two-part curve. These four cases are illustrated below.

The CATACAUSTIC for PARALLEL rays crossing a CIRCLE is a CARDIROID.

see also CATACAUSTIC, CAUSTIC

### Circle-Circle Intersection

Let two CIRCLES of RADII  $R$  and  $r$  and centered at  $(0, 0)$  and  $(d, 0)$  intersect in a LENS-shaped region. The equations of the two circles are

$$x^2 + y^2 = R^2 \quad (1)$$

$$(x - d)^2 + y^2 = r^2. \quad (2)$$

Combining (1) and (2) gives

$$(x - d)^2 + (R^2 - x^2) = r^2. \quad (3)$$

Multiplying through and rearranging gives

$$x^2 - 2dx + d^2 - x^2 = r^2 - R^2. \quad (4)$$

Solving for  $x$  results in

$$x = \frac{d^2 - r^2 + R^2}{2d}. \quad (5)$$

The line connecting the cusps of the LENS therefore has half-length given by plugging  $x$  back in to obtain

$$\begin{aligned} y^2 &= R^2 - x^2 = R^2 - \left( \frac{d^2 - r^2 + R^2}{2d} \right)^2 \\ &= \frac{4d^2 R^2 - (d^2 - r^2 + R^2)^2}{4d^2}, \end{aligned} \quad (6)$$

giving a length of

$$\begin{aligned} a &= \frac{1}{d} \sqrt{4d^2 R^2 - (d^2 - r^2 + R^2)^2} \\ &= \frac{1}{d} [(-d + r - R)(-d - r + R) \\ &\quad \times [(-d + r + R)(d + r + R)]^{1/2}. \end{aligned} \quad (7)$$

This same formulation applies directly to the SPHERE-SPHERE INTERSECTION problem.

To find the AREA of the asymmetric "LENS" in which the CIRCLES intersect, simply use the formula for the circular SEGMENT of radius  $R'$  and triangular height  $d'$

$$A(R', d') = R'^2 \cos^{-1} \left( \frac{d'}{R'} \right) - d' \sqrt{R'^2 - d'^2} \quad (8)$$

twice, one for each half of the "LENS." Noting that the heights of the two segment triangles are

$$d_1 = x = \frac{d^2 - r^2 + R^2}{2d} \quad (9)$$

$$d_2 = d - x = \frac{d^2 + r^2 - R^2}{2d}. \quad (10)$$

The result is

$$\begin{aligned} A &= A(R_1, d_1) + A(R_2, d_2) \\ &= r^2 \cos^{-1} \left( \frac{d^2 + r^2 - R^2}{2dr} \right) \\ &\quad + R^2 \cos^{-1} \left( \frac{d^2 + R^2 - r^2}{2dR} \right) \\ &\quad - \frac{1}{2} \sqrt{(d - r - R)(d + r - R)(d - r + R)(d + r + R)}. \end{aligned} \quad (11)$$

The limiting cases of this expression can be checked to give 0 when  $d = R + r$  and

$$A = 2R^2 \cos^{-1} \left( \frac{d}{2R} \right) - \frac{1}{2} d \sqrt{4R^2 - d^2} \quad (12)$$

$$= 2A(\frac{1}{2}d, R) \quad (13)$$

when  $r = R$ , as expected. In order for half the area of two UNIT DISKS ( $R = 1$ ) to overlap, set  $A = \pi R^2/2 = \pi/2$  in the above equation

$$\frac{1}{2}\pi = 2 \cos^{-1}(\frac{1}{2}d) - \frac{1}{2}d\sqrt{4 - d^2} \quad (14)$$

and solve numerically, yielding  $d \approx 0.807946$ .

see also LENS, SEGMENT, SPHERE-SPHERE INTERSECTION

### Circle Cutting

Determining the maximum number of pieces in which it is possible to divide a CIRCLE for a given number of cuts is called the circle cutting, or sometimes PANCAKE CUTTING, problem. The minimum number is always  $n + 1$ , where  $n$  is the number of cuts, and it is always possible to obtain any number of pieces between the minimum and maximum. The first cut creates 2 regions, and the  $n$ th cut creates  $n$  new regions, so

$$f(1) = 2 \quad (1)$$

$$f(2) = 2 + f(1) \quad (2)$$

$$f(n) = n + f(n - 1). \quad (3)$$

Therefore,

$$\begin{aligned} f(n) &= n + [(n - 1) + f(n - 2)] \\ &= n + (n - 1) + \dots + 2 + f(1) = \sum_{k=2}^n kf(1) \\ &= \sum_{k=1}^n k - 1 + f(1) = \frac{1}{2}n(n + 1) - 1 + 2 \\ &= \frac{1}{2}(n^2 + n + 2). \end{aligned} \quad (4)$$

Evaluating for  $n = 1, 2, \dots$  gives 2, 4, 7, 11, 16, 22, ... (Sloane's A000124).

A related problem, sometimes called MOSER'S CIRCLE PROBLEM, is to find the number of pieces into which a CIRCLE is divided if  $n$  points on its CIRCUMFERENCE

are joined by CHORDS with no three CONCURRENT. The answer is

$$g(n) = \binom{n}{4} + \binom{n}{2} + 1 \quad (5)$$

$$= \frac{1}{24}(n^4 - 6n^3 + 23n^2 - 18n + 24), \quad (6)$$

(Yaglom and Yaglom 1987, Guy 1988, Conway and Guy 1996, Noy 1996), where  $\binom{n}{m}$  is a BINOMIAL COEFFICIENT. The first few values are 1, 2, 4, 8, 16, 31, 57, 99, 163, 256, ... (Sloane's A000127). This sequence and problem are an example of the danger in making assumptions based on limited trials. While the series starts off like  $2^{n-1}$ , it begins differing from this GEOMETRIC SERIES at  $n = 6$ .

### Circle Evolute

$$x = \cos t \quad x' = -\sin t \quad x'' = -\cos t \quad (1)$$

$$y = \sin t \quad y' = \cos t \quad y'' = -\sin t, \quad (2)$$

so the RADIUS OF CURVATURE is

$$R = \frac{(x'^2 + y'^2)^{3/2}}{y''x' - x''y'} = \frac{(\sin^2 t + \cos^2 t)^{3/2}}{(-\sin t)(-\sin t) - (-\cos t)\cos t} = 1, \quad (3)$$

and the TANGENT VECTOR is

$$\hat{\mathbf{T}} = \begin{bmatrix} -\sin t \\ \cos t \end{bmatrix}. \quad (4)$$

Therefore,

$$\cos \tau = \hat{\mathbf{T}} \cdot \hat{\mathbf{x}} = -\sin t \quad (5)$$

$$\sin \tau = \hat{\mathbf{T}} \cdot \hat{\mathbf{y}} = \cos t, \quad (6)$$

so

$$\xi(t) = x - R \sin \tau = \cos t - 1 \cdot \cos t = 0 \quad (7)$$

$$\eta(t) = y + R \cos \tau = \sin t + 1 \cdot (-\sin t) = 0, \quad (8)$$

and the EVOLUTE degenerates to a POINT at the ORIGIN.

see also CIRCLE INVOLUTE

### Circle Inscribing

If  $r$  is the RADIUS of a CIRCLE inscribed in a RIGHT TRIANGLE with sides  $a$  and  $b$  and HYPOTENUSE  $c$ , then

$$r = \frac{1}{2}(a + b - c).$$

see INSCRIBED, POLYGON

### Circle Involute

First studied by Huygens when he was considering clocks without pendula for use on ships at sea. He used the circle involute in his first pendulum clock in an attempt to force the pendulum to swing in the path of a CYCLOID.

For a CIRCLE with  $a = 1$ , the parametric equations of the circle and their derivatives are given by

$$x = \cos t \quad x' = -\sin t \quad x'' = -\cos t \quad (1)$$

$$y = \sin t \quad y' = \cos t \quad y'' = -\sin t. \quad (2)$$

The TANGENT VECTOR is

$$\hat{\mathbf{T}} = \begin{bmatrix} -\sin t \\ \cos t \end{bmatrix} \quad (3)$$

and the ARC LENGTH along the circle is

$$s = \int \sqrt{x'^2 + y'^2} dt = \int dt = t, \quad (4)$$

so the involute is given by

$$\mathbf{r}_i = \mathbf{r} - s\hat{\mathbf{T}} = \begin{bmatrix} \cos t \\ \sin t \end{bmatrix} - t \begin{bmatrix} -\sin t \\ \cos t \end{bmatrix} = \begin{bmatrix} \cos t + t \sin t \\ \sin t - t \cos t \end{bmatrix}, \quad (5)$$

or

$$x = a(\cos t + t \sin t) \quad (6)$$

$$y = a(\sin t - t \cos t). \quad (7)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s = \int ds = \int \sqrt{x'^2 + y'^2} dt = \frac{1}{2}at^2 \quad (8)$$

$$\kappa = \frac{1}{at} \quad (9)$$

$$\phi = t. \quad (10)$$

The CESÀRO EQUATION is

$$\kappa = \frac{1}{\sqrt{as}}. \quad (11)$$

### Circle Involute Pedal Curve

The PEDAL CURVE of CIRCLE INVOLUTE

$$f = \cos t + t \sin t$$

$$g = \sin t - t \cos t$$

with the center as the PEDAL POINT is the ARCHIMEDES' SPIRAL

$$x = t \sin t$$

$$y = -t \cos t.$$

### Circle Lattice Points

For every POSITIVE INTEGER  $n$ , there exists a CIRCLE which contains exactly  $n$  lattice points in its interior. H. Steinhaus proved that for every POSITIVE INTEGER  $n$ , there exists a CIRCLE of AREA  $n$  which contains exactly  $n$  lattice points in its interior.

### Circle Lattice Points

SCHINZEL'S THEOREM shows that for every POSITIVE INTEGER  $n$ , there exists a CIRCLE in the PLANE having exactly  $n$  LATTICE POINTS on its CIRCUMFERENCE. The theorem also explicitly identifies such "SCHINZEL CIRCLES" as

$$\begin{cases} (x - \frac{1}{2})^2 + y^2 = \frac{1}{4}5^{k-1} & \text{for } n = 2k \\ (x - \frac{1}{3})^2 + y^2 = \frac{1}{9}5^{2k} & \text{for } n = 2k + 1. \end{cases} \quad (1)$$

Note, however, that these solutions do not necessarily have the smallest possible RADIUS. For example, while the SCHINZEL CIRCLE centered at  $(1/3, 0)$  and with RADIUS  $625/3$  has nine lattice points on its CIRCUMFERENCE, so does the CIRCLE centered at  $(1/3, 0)$  with RADIUS  $65/3$ .

Let  $r$  be the smallest INTEGER RADIUS of a CIRCLE centered at the ORIGIN  $(0, 0)$  with  $L(r)$  LATTICE POINTS. In order to find the number of lattice points of the CIRCLE, it is only necessary to find the number in the first octant, i.e., those with  $0 \leq y \leq \lfloor r/\sqrt{2} \rfloor$ , where  $\lfloor z \rfloor$  is the FLOOR FUNCTION. Calling this  $N(r)$ , then for  $r \geq 1$ ,  $L(r) = 8N(r) - 4$ , so  $L(r) \equiv 4 \pmod{8}$ . The multiplication by eight counts all octants, and the subtraction by four eliminates points on the axes which the multiplication counts twice. (Since  $\sqrt{2}$  is IRRATIONAL, the MIDPOINT of a arc is never a LATTICE POINT.)

GAUSS'S CIRCLE PROBLEM asks for the number of lattice points *within* a CIRCLE of RADIUS  $r$

$$N(r) = 1 + 4 \lfloor r \rfloor + 4 \sum_{i=1}^{\lfloor r \rfloor} \left\lfloor \sqrt{r^2 - i^2} \right\rfloor. \quad (2)$$

Gauss showed that

$$N(r) = \pi r^2 + E(r), \quad (3)$$

where

$$|E(r)| \leq 2\sqrt{2}\pi r. \quad (4)$$

The number of lattice points on the CIRCUMFERENCE of circles centered at  $(0, 0)$  with radii  $0, 1, 2, \dots$  are  $1, 4, 4, 4, 12, 4, 4, 4, 12, 4, 4, \dots$  (Sloane's A046109). The following table gives the smallest RADIUS  $r \leq 111,000$  for a circle centered at  $(0, 0)$  having a given number of LATTICE POINTS  $L(r)$ . Note that the high water mark radii are always multiples of five.

$L(r)$	$r$
1	0
4	1
12	5
20	25
28	125
36	65
44	3,125
52	15,625
60	325
68	$\leq 390,625$
76	$\leq 1,953,125$
84	1,625
92	$\leq 48,828,125$
100	4,225
108	1,105
132	40,625
140	21,125
180	5,525
252	27,625
300	71,825
324	32,045

If the CIRCLE is instead centered at  $(1/2, 0)$ , then the CIRCLES of RADII  $1/2, 3/2, 5/2, \dots$  have 2, 2, 6, 2, 2, 2, 6, 6, 2, 2, 2, 10, 2, ... (Sloane's A046110) on their CIRCUMFERENCES. If the CIRCLE is instead centered at  $(1/3, 0)$ , then the number of lattice points on the CIRCUMFERENCE of the CIRCLES of RADIUS  $1/3, 2/3, 4/3, 5/3, 7/3, 8/3, \dots$  are 1, 1, 1, 3, 1, 1, 3, 1, 3, 1, 1, 3, 1, 3, 1, 1, 5, 3, ... (Sloane's A046111).

Let

1.  $a_n$  be the RADIUS of the CIRCLE centered at  $(0, 0)$  having  $8n + 4$  lattice points on its CIRCUMFERENCE,
2.  $b_n/2$  be the RADIUS of the CIRCLE centered at  $(1/2, 0)$  having  $4n + 2$  lattice points on its CIRCUMFERENCE,
3.  $c_n/3$  be the RADIUS of CIRCLE centered at  $(1/3, 0)$  having  $2n + 1$  lattice points on its CIRCUMFERENCE.

Then the sequences  $\{a_n\}$ ,  $\{b_n\}$ , and  $\{c_n\}$  are equal, with the exception that  $b_n = 0$  if  $2|n$  and  $c_n = 0$  if  $3|n$ . However, the sequences of *smallest* radii having the above numbers of lattice points are equal in the three cases

and given by 1, 5, 25, 125, 65, 3125, 15625, 325, ... (Sloane's A046112).

KULIKOWSKI'S THEOREM states that for every POSITIVE INTEGER  $n$ , there exists a 3-D SPHERE which has exactly  $n$  LATTICE POINTS on its surface. The SPHERE is given by the equation

$$(x - a)^2 + (y - b)^2 + (z - \sqrt{2})^2 = c^2 + 2,$$

where  $a$  and  $b$  are the coordinates of the center of the so-called SCHINZEL CIRCLE and  $c$  is its RADIUS (Honsberger 1973).

see also CIRCLE, CIRCUMFERENCE, GAUSS'S CIRCLE PROBLEM, KULIKOWSKI'S THEOREM, LATTICE POINT, SCHINZEL CIRCLE, SCHINZEL'S THEOREM

#### Circle Lattice Theorem

see GAUSS'S CIRCLE PROBLEM

#### Circle Map

A 1-D MAP which maps a CIRCLE onto itself

$$\theta_{n+1} = \theta_n + \Omega - \frac{K}{2\pi} \sin(2\pi\theta_n), \quad (1)$$

where  $\theta_{n+1}$  is computed mod 1. Note that the circle map has two parameters:  $\Omega$  and  $K$ .  $\Omega$  can be interpreted as an externally applied frequency, and  $K$  as a strength of nonlinearity. The 1-D JACOBIAN is

$$\frac{\partial \theta_{n+1}}{\partial \theta_n} = 1 - K \cos(2\pi\theta_n), \quad (2)$$

so the circle map is not AREA-PRESERVING. It is related to the STANDARD MAP

$$I_{n+1} = I_n + \frac{K}{2\pi} \sin(2\pi\theta_n) \quad (3)$$

$$\theta_{n+1} = \theta_n + I_{n+1}, \quad (4)$$

for  $I$  and  $\theta$  computed mod 1. Writing  $\theta_{n+1}$  as

$$\theta_{n+1} = \theta_n + I_n + \frac{K}{2\pi} \sin(2\pi\theta_n) \quad (5)$$

gives the circle map with  $I_n = \Omega$  and  $K = -K$ . The unperturbed circle map has the form

$$\theta_{n+1} = \theta_n + \Omega. \quad (6)$$

If  $\Omega$  is RATIONAL, then it is known as the map WINDING NUMBER, defined by

$$\Omega = W \equiv \frac{p}{q}, \quad (7)$$

and implies a periodic trajectory, since  $\theta_n$  will return to the same point (at most) every  $q$  ORBITS. If  $\Omega$  is IRRATIONAL, then the motion is quasiperiodic. If  $K$  is NONZERO, then the motion may be periodic in some finite region surrounding each RATIONAL  $\Omega$ . This execution of periodic motion in response to an IRRATIONAL forcing is known as MODE LOCKING.

If a plot is made of  $K$  vs.  $\Omega$  with the regions of periodic MODE-LOCKED parameter space plotted around RATIONAL  $\Omega$  values (WINDING NUMBERS), then the regions are seen to widen upward from 0 at  $K = 0$  to some finite width at  $K = 1$ . The region surrounding each RATIONAL NUMBER is known as an ARNOLD TONGUE. At  $K = 0$ , the ARNOLD TONGUES are an isolated set of MEASURE zero. At  $K = 1$ , they form a CANTOR SET of DIMENSION  $d \approx 0.08700$ . For  $K > 1$ , the tongues overlap, and the circle map becomes noninvertible. The circle map has a FEIGENBAUM CONSTANT

$$\delta \equiv \lim_{n \rightarrow \infty} \frac{\theta_n - \theta_{n-1}}{\theta_{n+1} - \theta_n} = 2.833. \quad (8)$$

see also ARNOLD TONGUE, DEVIL'S STAIRCASE, MODE LOCKING, WINDING NUMBER (MAP)

### Circle Method

see PARTITION FUNCTION  $P$

### Circle Negative Pedal Curve

The NEGATIVE PEDAL CURVE of a circle is an ELLIPSE if the PEDAL POINT is inside the CIRCLE, and a HYPERBOLA if the PEDAL POINT is outside the CIRCLE.

### Circle Notation

A NOTATION for LARGE NUMBERS due to Steinhaus (1983) in which  $\textcircled{n}$  is defined in terms of STEINHAUS-MOSER NOTATION as  $n$  in  $n$  SQUARES. The particular number known as the MEGA is then defined as follows.

$$\textcircled{2} = \boxed{4} = \boxed{\triangle 2} = \boxed{\triangle 2^2} = \boxed{4^4} = \boxed{256}$$

see also MEGA, MEGISTRON, STEINHAUS-MOSER NOTATION

### References

Steinhaus, H. *Mathematical Snapshots*, 3rd American ed. New York: Oxford University Press, pp. 28–29, 1983.

### Circle Order

A POSET  $P$  is a circle order if it is ISOMORPHIC to a SET of DISKS ordered by containment.

see also ISOMORPHIC POSETS, PARTIALLY ORDERED SET

### Circle Orthotomic

The ORTHOTOMIC of the CIRCLE represented by

$$x = \cos t \quad (1)$$

$$y = \sin t \quad (2)$$

with a source at  $(x, y)$  is

$$x = x \cos(2t) - y \sin(2t) + 2 \sin t \quad (3)$$

$$y = -x \sin(2t) - y \cos(2t) + 2 \cos t. \quad (4)$$

### Circle Packing

The densest packing of spheres in the PLANE is the hexagonal lattice of the bee's honeycomb (illustrated above), which has a PACKING DENSITY of

$$\eta = \frac{\pi}{2\sqrt{3}} = 0.9068996821\dots$$

Gauss proved that the hexagonal lattice is the densest plane *lattice* packing, and in 1940, L. Fejes Tóth proved that the hexagonal lattice is indeed the densest of *all* possible plane packings.

Solutions for the smallest diameter CIRCLES into which  $n$  UNIT CIRCLES can be packed have been proved optimal for  $n = 1$  through 10 (Kravitz 1967). The best known results are summarized in the following table.

$n$	$d$ exact	$d$ approx.
1	1	1.00000
2	2	2.00000
3	$1 + \frac{2}{3}\sqrt{3}$	2.15470...
4	$1 + \sqrt{2}$	2.41421...
5	$1 + \sqrt{2(1 + 1/\sqrt{5})}$	2.70130...
6	3	3.00000
7	3	3.00000
8	$1 + \csc(\pi/7)$	3.30476...
9	$1 + \sqrt{2(2 + \sqrt{2})}$	3.61312...
10		3.82...
11		
12		4.02...

For CIRCLE packing inside a SQUARE, proofs are known only for  $n = 1$  to 9.

$n$	$d$ exact	$d$ approx.
1	1	1.000
2		0.58...
3		0.500...
4	$\frac{1}{2}$	0.500
5		0.41...
6		0.37...
7		0.348...
8		0.341...
9	$\frac{1}{3}$	0.333...
10		0.148204...

The smallest SQUARE into which two UNIT CIRCLES, one of which is split into two pieces by a chord, can be packed is not known (Goldberg 1968, Ogilvy 1990).

#### Circle Pedal Curve

The PEDAL CURVE of a CIRCLE is a CARDIOID if the PEDAL POINT is taken on the CIRCUMFERENCE,

and otherwise a LIMAÇON.

#### Circle-Point Midpoint Theorem

Taking the locus of MIDPOINTS from a fixed point to a circle of radius  $r$  results in a circle of radius  $r/2$ . This follows trivially from

$$\begin{aligned} \mathbf{r}(\theta) &= \begin{bmatrix} -x \\ 0 \end{bmatrix} + \frac{1}{2} \left( \begin{bmatrix} r \cos \theta \\ r \sin \theta \end{bmatrix} - \begin{bmatrix} -x \\ 0 \end{bmatrix} \right) \\ &= \begin{bmatrix} \frac{1}{2} r \cos \theta - \frac{1}{2} x \\ \frac{1}{2} r \sin \theta \end{bmatrix}. \end{aligned}$$

#### References

### Circle Radial Curve

The RADIAL CURVE of a unit CIRCLE from a RADIAL POINT  $(x, 0)$  is another CIRCLE with parametric equations

$$\begin{aligned}x(t) &= x - \cos t \\y(t) &= -\sin t.\end{aligned}$$

### Circle Squaring

Construct a SQUARE equal in AREA to a CIRCLE using only a STRAIGHTEDGE and COMPASS. This was one of the three GEOMETRIC PROBLEMS OF ANTIQUITY, and was perhaps first attempted by Anaxagoras. It was finally proved to be an impossible problem when PI was proven to be TRANSCENDENTAL by Lindemann in 1882.

However, approximations to circle squaring are given by constructing lengths close to  $\pi = 3.1415926\dots$  Ramanujan (1913–14) and Olds (1963) give geometric constructions for  $355/113 = 3.1415929\dots$  Gardner (1966, pp. 92–93) gives a geometric construction for  $3 + 16/113 = 3.1415929\dots$  Dixon (1991) gives constructions for  $6/5(1 + \phi) = 3.141640\dots$  and  $\sqrt{4 + [3 - \tan(30^\circ)]} = 3.141533\dots$

While the circle cannot be squared in EUCLIDEAN SPACE, it *can* in GAUSS-BOLYAI-LOBACHEVSKY SPACE (Gray 1989).

### Circle Strophoid

The STROPHOID of a CIRCLE with pole at the center and fixed point on the CIRCUMFERENCE is a FREETH’S NEPHROID.

### Circle Tangents

There are four CIRCLES that touch all the sides of a given TRIANGLE. These are all touched by the CIRCLE through the intersection of the ANGLE BISECTORS of the TRIANGLE, known as the NINE-POINT CIRCLE.

Given the above figure,  $GE = FH$ , since

$$\begin{aligned}AB &= AG + GB = GE + GF = GE + (GE + EF) \\&= 2G + EF\end{aligned}$$

$$\begin{aligned}CD &= CH + HD = EH + FH = FH + (FH + EF) \\&= EF + 2FH.\end{aligned}$$

Because  $AB = CD$ , it follows that  $GE = FH$ .

The line tangent to a CIRCLE of RADIUS  $a$  centered at  $(x, y)$

$$\begin{aligned}x' &= x + a \cos t \\y' &= y + a \sin t\end{aligned}$$

through  $(0, 0)$  can be found by solving the equation

$$\begin{bmatrix} x + a \cos t \\ y + a \sin t \end{bmatrix} \cdot \begin{bmatrix} a \cos t \\ a \sin t \end{bmatrix} = 0,$$

giving

$$t = \pm \cos^{-1} \left( \frac{-ax \pm y \sqrt{x^2 + y^2 - a^2}}{x^2 + y^2} \right).$$

Two of these four solutions give tangent lines, as illustrated above.

#### Circuit

see CYCLE (GRAPH)

#### Circuit Rank

Also known as the CYCLOMATIC NUMBER. The circuit rank is the smallest number of EDGES  $\gamma$  which must be removed from a GRAPH of  $N$  EDGES and  $n$  nodes such that no CIRCUIT remains.

$$\gamma = N - n + 1.$$

#### Circulant Determinant

Gradshteyn and Ryzhik (1970) define circulants by

$$\begin{vmatrix} x_1 & x_2 & x_3 & \cdots & x_n \\ x_n & x_1 & x_2 & \cdots & x_{n-1} \\ x_{n-1} & x_n & x_1 & \cdots & x_{n-2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ x_2 & x_3 & x_4 & \cdots & x_1 \end{vmatrix} = \prod_{j=1}^n (x_1 + x_2 \omega_j + x_3 \omega_j^2 + \cdots + x_n \omega_j^{n-1}), \quad (1)$$

where  $\omega_j$  is the  $n$ th ROOT OF UNITY. The second-order circulant determinant is

$$\begin{vmatrix} x_1 & x_2 \\ x_2 & x_1 \end{vmatrix} = (x_1 + x_2)(x_1 - x_2), \quad (2)$$

and the third order is

$$\begin{vmatrix} x_1 & x_2 & x_3 \\ x_3 & x_1 & x_2 \\ x_2 & x_3 & x_1 \end{vmatrix} = (x_1 + x_2 + x_3)(x_1 + \omega x_2 + \omega^2 x_3)(x_1 + \omega^2 x_2 + \omega x_3), \quad (3)$$

where  $\omega$  and  $\omega^2$  are the COMPLEX CUBE ROOTS of UNITY.

The EIGENVALUES  $\lambda$  of the corresponding  $n \times n$  circulant matrix are

$$\lambda_j = x_1 + x_2 \omega_j + x_3 \omega_j^2 + \cdots + x_n \omega_j^{n-1}. \quad (4)$$

see also CIRCULANT MATRIX

Vardi, I. *Computational Recreations in Mathematica*. Reading, MA: Addison-Wesley, p. 114, 1991.

#### Circulant Graph

A GRAPH of  $n$  VERTICES in which the  $i$ th VERTEX is adjacent to the  $(i + j)$ th and  $(i - j)$ th VERTICES for each  $j$  in a list  $l$ .

#### Circulant Matrix

An  $n \times n$  MATRIX  $C$  defined as follows,

$$C = \begin{bmatrix} 1 & \binom{n}{1} & \binom{n}{2} & \cdots & \binom{n}{n-1} \\ \binom{n}{n-1} & 1 & \binom{n}{1} & \cdots & \binom{n}{n-2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \binom{n}{1} & \binom{n}{2} & \binom{n}{3} & \cdots & 1 \end{bmatrix}$$

$$C = \prod_{j=0}^{n-1} [(1 + \omega_j)^n - 1],$$

where  $\omega_0 \equiv 1$ ,  $\omega_1, \dots, \omega_{n-1}$  are the  $n$ th ROOTS OF UNITY. Circulant matrices are examples of LATIN SQUARES.

see also CIRCULANT DETERMINANT

#### Circular Cylindrical Coordinates

see CYLINDRICAL COORDINATES

#### Circular Functions

The functions describing the horizontal and vertical positions of a point on a CIRCLE as a function of ANGLE (COSINE and SINE) and those functions derived from them:

$$\cot x \equiv \frac{1}{\tan x} = \frac{\cos x}{\sin x} \quad (1)$$

$$\csc x \equiv \frac{1}{\sin x} \quad (2)$$

$$\sec x \equiv \frac{1}{\cos x} \quad (3)$$

$$\tan x \equiv \frac{\sin x}{\cos x}. \quad (4)$$

The study of circular functions is called TRIGONOMETRY.

see also COSECANT, COSINE, COTANGENT, ELLIPTIC FUNCTION, GENERALIZED HYPERBOLIC FUNCTIONS, HYPERBOLIC FUNCTIONS, SECANT, SINE, TANGENT, TRIGONOMETRY

#### References

Abramowitz, M. and Stegun, C. A. (Eds.). "Circular Functions." §4.3 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, pp. 71-79, 1972.

### Circular Permutation

The number of ways to arrange  $n$  distinct objects along a CIRCLE is

$$P_n = (n-1)!.$$

The number is  $(n-1)!$  instead of the usual FACTORIAL  $n!$  since all CYCLIC PERMUTATIONS of objects are equivalent because the CIRCLE can be rotated.

see also PERMUTATION, PRIME CIRCLE

### Circumcenter

The center  $O$  of a TRIANGLE'S CIRCUMCIRCLE. It can be found as the intersection of the PERPENDICULAR BISECTORS. If the TRIANGLE is ACUTE, the circumcenter is in the interior of the TRIANGLE. In a RIGHT TRIANGLE, the circumcenter is the MIDPOINT of the HYPOTENUSE.

$$\overline{OO_1} + \overline{OO_2} + \overline{OO_3} = R + r, \quad (1)$$

where  $O_i$  are the MIDPOINTS of sides  $A_i$ ,  $R$  is the CIRCUMRADIUS, and  $r$  is the INRADIUS (Johnson 1929, p. 190). The TRILINEAR COORDINATES of the circumcenter are

$$\cos A : \cos B : \cos C, \quad (2)$$

and the exact trilinears are therefore

$$R \cos A : R \cos B : R \cos C. \quad (3)$$

The AREAL COORDINATES are

$$\left(\frac{1}{2}a \cot A, \frac{1}{2}b \cot B, \frac{1}{2}c \cot C\right). \quad (4)$$

The distance between the INCENTER and circumcenter is  $\sqrt{R(R-2r)}$ . Given an interior point, the distances to the VERTICES are equal IFF this point is the circumcenter. It lies on the BROCARD AXIS.

The circumcenter  $O$  and ORTHOCENTER  $H$  are ISOGONAL CONJUGATES.

The ORTHOCENTER  $H$  of the PEDAL TRIANGLE  $\triangle O_1O_2O_3$  formed by the CIRCUMCENTER  $O$  concurs with the circumcenter  $O$  itself, as illustrated above. The circumcenter also lies on the EULER LINE.

see also BROCARD DIAMETER, CARNOT'S THEOREM, CENTROID (TRIANGLE), CIRCLE, EULER LINE, INCENTER, ORTHOCENTER

### Circumcircle

A TRIANGLE's circumscribed circle. Its center  $O$  is called the CIRCUMCENTER, and its RADIUS  $R$  the CIRCUMRADIUS. The circumcircle can be specified using TRILINEAR COORDINATES as

$$\beta\gamma a + \gamma\alpha b + \alpha\beta c = 0. \quad (1)$$

The STEINER POINT  $S$  and TARRY POINT  $T$  lie on the circumcircle.

A GEOMETRIC CONSTRUCTION for the circumcircle is given by Pedoe (1995, pp. xii–xiii). The equation for the circumcircle of the TRIANGLE with VERTICES  $(x_i, y_i)$  for  $i = 1, 2, 3$  is

$$\begin{vmatrix} x^2 + y^2 & x & y & 1 \\ x_1^2 + y_1^2 & x_1 & y_1 & 1 \\ x_2^2 + y_2^2 & x_2 & y_2 & 1 \\ x_3^2 + y_3^2 & x_3 & y_3 & 1 \end{vmatrix} = 0. \quad (2)$$

Expanding the DETERMINANT,

$$a(x^2 + y^2) + 2dx + 2fy + g = 0, \quad (3)$$

where

$$a = \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} \quad (4)$$

$$d = -\frac{1}{2} \begin{vmatrix} x_1^2 + y_1^2 & y_1 & 1 \\ x_2^2 + y_2^2 & y_2 & 1 \\ x_3^2 + y_3^2 & y_3 & 1 \end{vmatrix} \quad (5)$$

$$f = \frac{1}{2} \begin{vmatrix} x_1^2 + y_1^2 & x_1 & 1 \\ x_2^2 + y_2^2 & x_2 & 1 \\ x_3^2 + y_3^2 & x_3 & 1 \end{vmatrix} \quad (6)$$

$$g = - \begin{vmatrix} x_1^2 + y_1^2 & x_1 & y_1 \\ x_2^2 + y_2^2 & x_2 & y_2 \\ x_3^2 + y_3^2 & x_3 & y_3 \end{vmatrix}. \quad (7)$$

COMPLETING THE SQUARE gives

$$a \left( x + \frac{d}{a} \right)^2 + a \left( y + \frac{f}{a} \right)^2 - \frac{d^2}{a} - \frac{f^2}{a} + g = 0 \quad (8)$$

which is a CIRCLE of the form

$$(x - x_0)^2 + (y - y_0)^2 = r^2, \quad (9)$$

with CIRCUMCENTER

$$x_0 = -\frac{d}{a} \quad (10)$$

$$y_0 = -\frac{f}{a} \quad (11)$$

and CIRCUMRADIUS

$$r = \sqrt{\frac{f^2 + d^2}{a^2} - \frac{g}{a}}. \quad (12)$$

see also CIRCLE, CIRCUMCENTER, CIRCUMRADIUS, EX-CIRCLE, INCIRCLE, PARRY POINT, PURSER'S THEOREM, STEINER POINTS, TARRY POINT

#### References

Pedoe, D. *Circles: A Mathematical View*, rev. ed. Washington, DC: Math. Assoc. Amer., 1995.

#### Circumference

The PERIMETER of a CIRCLE. For RADIUS  $r$  or DIAMETER  $d = 2r$ ,

$$C = 2\pi r = \pi d,$$

where  $\pi$  is PI.

see also CIRCLE, DIAMETER, PERIMETER, PI, RADIUS

#### Circuminscribed

Given two closed curves, the circuminscribed curve is simultaneously INSCRIBED in the outer one and CIRCUMSCRIBED on the inner one.

see also PONCELET'S CLOSURE THEOREM

#### Circumradius

The radius of a TRIANGLE's CIRCUMCIRCLE or of a POLYHEDRON's CIRCUMSPHERE, denoted  $R$ . For a TRIANGLE,

$$R = \frac{abc}{\sqrt{(a+b+c)(b+c-a)(c+a-b)(a+b-c)}}, \quad (1)$$

where the side lengths of the TRIANGLE are  $a$ ,  $b$ , and  $c$ .

This equation can also be expressed in terms of the RADII of the three mutually tangent CIRCLES centered at the TRIANGLE's VERTICES. Relabeling the diagram for the SODDY CIRCLES with VERTICES  $O_1$ ,  $O_2$ , and  $O_3$  and the radii  $r_1$ ,  $r_2$ , and  $r_3$ , and using

$$a = r_1 + r_2 \quad (2)$$

$$b = r_2 + r_3 \quad (3)$$

$$c = r_1 + r_3 \quad (4)$$

then gives

$$R = \frac{(r_1 + r_2)(r_1 + r_3)(r_2 + r_3)}{4\sqrt{r_1 r_2 r_3 (r_1 + r_2 + r_3)}}. \quad (5)$$

If  $O$  is the CIRCUMCENTER and  $M$  is the triangle CENTROID, then

$$\overline{OM}^2 = R^2 - \frac{1}{9}(a^2 + b^2 + c^2). \quad (6)$$

$$Rr = \frac{a_1 a_2 a_3}{4s} \quad (7)$$

$$\cos \alpha_1 + \cos \alpha_2 + \cos \alpha_3 = 1 + \frac{r}{R} \quad (8)$$

$$r = 2R \cos \alpha_1 \cos \alpha_2 \cos \alpha_3 \quad (9)$$

$$a_1^2 + a_2^2 + a_3^2 = 4rR + 8R^2 \quad (10)$$

(Johnson 1929, pp. 189–191). Let  $d$  be the distance between INRADIUS  $r$  and circumradius  $R$ ,  $d = \overline{rR}$ . Then

$$R^2 - d^2 = 2Rr \quad (11)$$

$$\frac{1}{R-d} + \frac{1}{R+d} = \frac{1}{r} \quad (12)$$

(Mackay 1886–87). These and many other identities are given in Johnson (1929, pp. 186–190).

For an ARCHIMEDEAN SOLID, expressing the circumradius in terms of the INRADIUS  $r$  and MIDRADIUS  $\rho$  gives

$$R = \frac{1}{2}(r + \sqrt{r^2 + a^2}) \quad (13)$$

$$= \sqrt{\rho^2 + \frac{1}{4}a^2} \quad (14)$$

for an ARCHIMEDEAN SOLID.

### Cissoïd of Diocles

A curve invented by Diocles in about 180 BC in connection with his attempt to duplicate the cube by geometrical methods. The name "cissoïd" first appears in the work of Geminus about 100 years later. Fermat and Roberval constructed the tangent in 1634. Huygens and Wallis found, in 1658, that the AREA between the curve and its asymptote was  $3a$  (MacTutor Archive). From a given point there are either one or three TANGENTS to the cissoïd.

Given an origin  $O$  and a point  $P$  on the curve, let  $S$  be the point where the extension of the line  $OP$  intersects the line  $x = 2a$  and  $R$  be the intersection of the CIRCLE of RADIUS  $a$  and center  $(a, 0)$  with the extension of  $OP$ . Then the cissoïd of Diocles is the curve which satisfies  $OP = RS$ .

The cissoïd of Diocles is the ROULETTE of the VERTEX of a PARABOLA rolling on an equal PARABOLA. Newton gave a method of drawing the cissoïd of Diocles using two line segments of equal length at RIGHT ANGLES. If they are moved so that one line always passes through a fixed point and the end of the other line segment slides along a straight line, then the MIDPOINT of the sliding line segment traces out a cissoïd of Diocles.

The cissoïd of Diocles is given by the parametric equations

$$x = 2a \sin^2 \theta \quad (1)$$

$$y = \frac{2a \sin^3 \theta}{\cos \theta}. \quad (2)$$

Converting these to POLAR COORDINATES gives

$$\begin{aligned} r^2 = x^2 + y^2 &= 4a^2 \left( \sin^4 \theta + \frac{\sin^6 \theta}{\cos^2 \theta} \right) \\ &= 4a^2 \sin^4 \theta (1 + \tan^2 \theta) = 4a^2 \sin^4 \theta \sec^2 \theta, \end{aligned} \quad (3)$$

so

$$r = 2a \sin^2 \theta \sec \theta = 2a \sin \theta \tan \theta. \quad (4)$$

In CARTESIAN COORDINATES,

$$\begin{aligned} \frac{x^3}{2a - x} &= \frac{8a^3 \sin^6 \theta}{2a - 2a \sin^2 \theta} = 4a^2 \frac{\sin^6 \theta}{1 - \sin^2 \theta} \\ &= 4a^2 \frac{\sin^6 \theta}{\cos^2 \theta} = y^2. \end{aligned} \quad (5)$$

An equivalent form is

$$x(x^2 + y^2) = 2ay^2. \quad (6)$$

Using the alternative parametric form

$$x(t) = \frac{2at^2}{1+t^2} \quad (7)$$

$$y(t) = \frac{2at^3}{1+t^2} \quad (8)$$

(Gray 1993), gives the CURVATURE as

$$\kappa(t) = \frac{3}{a|t|(t^2 + 4)^{3/2}}. \quad (9)$$

### Clark's Triangle

A NUMBER TRIANGLE created by setting the VERTEX equal to 0, filling one diagonal with 1s, the other diagonal with multiples of an INTEGER  $f$ , and filling in the remaining entries by summing the elements on either side from one row above. Call the first column  $n = 0$  and the last column  $m = n$  so that

$$c(m, 0) = fm \quad (1)$$

$$c(m, m) = 1, \quad (2)$$

then use the RECURRENCE RELATION

$$c(m, n) = c(m-1, n-1) + c(m-1, n) \quad (3)$$

to compute the rest of the entries. For  $n = 1$ , we have

$$c(m, 1) = c(m-1, 0) + c(m-1, 1) \quad (4)$$

$$c(m, 1) - c(m-1, 1) = c(m-1, 0) = f(m-1). \quad (5)$$

For arbitrary  $m$ , the value can be computed by SUMMING this RECURRENCE,

$$c(m, 1) = f \left( \sum_{k=1}^{m-1} k \right) + 1 = \frac{1}{2} fm(m-1) + 1. \quad (6)$$

Now, for  $n = 2$  we have

$$c(m, 2) = c(m-1, 1) + c(m-1, 2) \quad (7)$$

$$c(m, 2) - c(m-1, 2) = c(m-1, 1) = \frac{1}{2} f(m-1)m + 1, \quad (8)$$

so SUMMING the RECURRENCE gives

$$\begin{aligned} c(m, 2) &= \sum_{k=1}^m [\frac{1}{2} fk(k-1) + 1] = \sum_{k=1}^m (\frac{1}{2} fk^2 - \frac{1}{2} fk + 1) \\ &= \frac{1}{2} f[\frac{1}{6} m(m+1)(2m+1)] - \frac{1}{2} f[\frac{1}{2} m(m+1)] + m \\ &= \frac{1}{6} (m-1)(fm^2 - 2fm + 6). \end{aligned} \quad (9)$$

Similarly, for  $n = 3$  we have

$$\begin{aligned} c(m, 3) - c(m-1, 3) &= c(m-1, 2) \\ &= \frac{1}{6} fm^3 - fm^2 + (\frac{11}{6}f + 1)m - (f+2). \end{aligned} \quad (10)$$

Taking the SUM,

$$c(m, 3) = \sum_{k=2}^m \frac{1}{6} fk^3 - fk^2 + (\frac{11}{6}f + 1)k - (f+2). \quad (11)$$

Evaluating the SUM gives

$$c(m, 3) = \frac{1}{24} (m-1)(m-2)(fm^2 - 3fm + 12). \quad (12)$$

So far, this has just been relatively boring ALGEBRA. But the amazing part is that if  $f = 6$  is chosen as the INTEGER, then  $c(m, 2)$  and  $c(m, 3)$  simplify to

$$\begin{aligned} c(m, 2) &= \frac{1}{6} (m-1)(6m^2 - 12m + 6) \\ &= (m-1)^3 \end{aligned} \quad (13)$$

$$c(m, 3) = \frac{1}{4} (m-1)^2 (m-2)^2, \quad (14)$$

which are consecutive CUBES  $(m-1)^3$  and nonconsecutive SQUARES  $n^2 = [(m-1)(m-2)/2]^2$ .

#### Class (Map)

A MAP  $u: \mathbb{R}^n \rightarrow \mathbb{R}^n$  from a DOMAIN  $G$  is called a map of class  $C^r$  if each component of

$$u(x) = (u_1(x_1, \dots, x_n), \dots, u_m(x_1, \dots, x_n))$$

is of class  $C^r$  ( $0 \leq r \leq \infty$  or  $r = \omega$ ) in  $G$ , where  $C^d$  denotes a continuous function which is differentiable  $d$  times.

#### Class (Multiply Perfect Number)

The number  $k$  in the expression  $s(n) = kn$  for a MULTIPLY PERFECT NUMBER is called its class.

#### Class Number

For any IDEAL  $I$ , there is an IDEAL  $I_i$  such that

$$II_i = z, \quad (1)$$

where  $z$  is a PRINCIPAL IDEAL, (i.e., an IDEAL of rank 1). Moreover, there is a finite list of ideals  $I_i$  such that this equation may be satisfied for every  $I$ . The size of this list is known as the class number. When the class number is 1, the RING corresponding to a given IDEAL has unique factorization and, in a sense, the class

number is a measure of the failure of unique factorization in the original number ring.

A finite series giving exactly the class number of a RING is known as a CLASS NUMBER FORMULA. A CLASS NUMBER FORMULA is known for the full ring of cyclotomic integers, as well as for any subring of the cyclotomic integers. Finding the class number is a computationally difficult problem.

Let  $h(d)$  denote the class number of a quadratic ring, corresponding to the BINARY QUADRATIC FORM

$$ax^2 + bxy + cy^2, \quad (2)$$

with DISCRIMINANT

$$d \equiv b^2 - 4ac. \quad (3)$$

Then the class number  $h(d)$  for DISCRIMINANT  $d$  gives the number of possible factorizations of  $ax^2 + bxy + cy^2$  in the QUADRATIC FIELD  $\mathbb{Q}(\sqrt{d})$ . Here, the factors are of the form  $x + y\sqrt{d}$ , with  $x$  and  $y$  half INTEGERS.

Some fairly sophisticated mathematics shows that the class number for discriminant  $d$  can be given by the CLASS NUMBER FORMULA

$$h(d) \equiv \begin{cases} -\frac{1}{2 \ln \eta} \sum_{r=1}^{d-1} (d|r) \ln \sin\left(\frac{\pi r}{d}\right) & \text{for } d > 0 \\ -\frac{w(d)}{2|d|} \sum_{r=1}^{|d|-1} (d|r) r & \text{for } d < 0, \end{cases} \quad (4)$$

where  $(d|r)$  is the KRONECKER SYMBOL,  $\eta(d)$  is the FUNDAMENTAL UNIT,  $w(d)$  is the number of substitutions which leave the BINARY QUADRATIC FORM unchanged

$$w(d) = \begin{cases} 6 & \text{for } d = -3 \\ 4 & \text{for } d = -4 \\ 2 & \text{otherwise,} \end{cases} \quad (5)$$

and the sums are taken over all terms where the KRONECKER SYMBOL is defined (Cohn 1980). The class number for  $d > 0$  can also be written

$$\eta^{2h(d)} = \prod_{r=1}^{d-1} \sin^{-(d|r)}\left(\frac{\pi r}{d}\right) \quad (6)$$

for  $d > 0$ , where the PRODUCT is taken over terms for which the KRONECKER SYMBOL is defined.

The class number is related to the DIRICHLET  $L$ -SERIES by

$$h(d) = \frac{L_d(1)}{\kappa(d)}, \quad (7)$$

where  $\kappa(d)$  is the DIRICHLET STRUCTURE CONSTANT.

Wagner (1996) shows that class number  $h(-d)$  satisfies the INEQUALITY

$$h(-d) > \frac{1}{55} \prod_{p|d}^* \left(1 - \frac{|2\sqrt{p}|}{p+1}\right) \ln d, \quad (8)$$

for  $-d < 0$ , where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, the product is over PRIMES dividing  $d$ , and the  $*$  indicates that the GREATEST PRIME FACTOR of  $d$  is omitted from the product.

The *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL) function `NumberTheory`NumberTheoryFunctions`ClassNumber[n]` gives the class number  $h(d)$  for  $d$  a NEGATIVE SQUAREFREE number of the form  $4k+1$ .

GAUSS'S CLASS NUMBER PROBLEM asks to determine a complete list of fundamental DISCRIMINANTS  $-d$  such that the CLASS NUMBER is given by  $h(-d) = m$  for a given  $m$ . This problem has been solved for  $n \leq 7$  and ODD  $n \leq 23$ . Gauss conjectured that the class number  $h(-d)$  of an IMAGINARY quadratic field with DISCRIMINANT  $-d$  tends to infinity with  $d$ , an assertion now known as GAUSS'S CLASS NUMBER CONJECTURE.

The discriminants  $d$  having  $h(-d) = 1, 2, 3, 4, 5, \dots$  are Sloane's A014602 (Cohen 1993, p. 229; Cox 1997, p. 271), Sloane's A014603 (Cohen 1993, p. 229), Sloane's A006203 (Cohen 1993, p. 504), Sloane's A013658 (Cohen 1993, p. 229), Sloane's A046002, Sloane's A046003, .... The complete set of negative discriminants having class numbers 1–5 and ODD 7–23 are known. Buell (1977) gives the smallest and largest fundamental class numbers for  $d < 4,000,000$ , partitioned into EVEN discriminants, discriminants 1 (mod 8), and discriminants 5 (mod 8). Arno *et al.* (1993) give complete lists of values of  $d$  with  $h(-d) = k$  for ODD  $k = 5, 7, 9, \dots, 23$ . Wagner gives complete lists of values for  $k = 5, 6$ , and 7.

Lists of NEGATIVE discriminants corresponding to IMAGINARY QUADRATIC FIELDS  $\mathbb{Q}(\sqrt{-d(n)})$  having small class numbers  $h(-d)$  are given in the table below. In the table,  $N$  is the number of "fundamental" values of  $-d$  with a given class number  $h(-d)$ , where "fundamental" means that  $-d$  is not divisible by any SQUARE NUMBER  $s^2$  such that  $h(-d/s^2) < h(-d)$ . For example, although  $h(-63) = 2$ ,  $-63$  is not a fundamental discriminant since  $63 = 3^2 \cdot 7$  and  $h(-63/3^2) = h(-7) = 1 < h(-63)$ . EVEN values  $8 \leq h(-d) \leq 18$  have been computed by Weisstein. The number of negative discriminants having class number 1, 2, 3, ... are 9, 18, 16, 54, 25, 51, 31, ... (Sloane's A046125). The largest negative discriminants having class numbers 1, 2, 3, ... are 163, 427, 907, 1555, 2683, ... (Sloane's A038552).

The following table lists the numbers with small class numbers  $\leq 11$ . Lists including larger class numbers are given by Weisstein.

$h(-d)$	$N$	$d$
1	9	3, 4, 7, 8, 11, 19, 43, 67, 163
2	18	15, 20, 24, 35, 40, 51, 52, 88, 91, 115, 123, 148, 187, 232, 235, 267, 403, 427
3	16	23, 31, 59, 83, 107, 139, 211, 283, 307, 331, 379, 499, 547, 643, 883, 907

$h(-d)$	$N$	$d$
4	54	39, 55, 56, 68, 84, 120, 132, 136, 155, 168, 184, 195, 203, 219, 228, 259, 280, 291, 292, 312, 323, 328, 340, 355, 372, 388, 408, 435, 483, 520, 532, 555, 568, 595, 627, 667, 708, 715, 723, 760, 763, 772, 795, 955, 1003, 1012, 1027, 1227, 1243, 1387, 1411, 1435, 1507, 1555
5	25	47, 79, 103, 127, 131, 179, 227, 347, 443, 523, 571, 619, 683, 691, 739, 787, 947, 1051, 1123, 1723, 1747, 1867, 2203, 2347, 2683
6	51	87, 104, 116, 152, 212, 244, 247, 339, 411, 424, 436, 451, 472, 515, 628, 707, 771, 808, 835, 843, 856, 1048, 1059, 1099, 1108, 1147, 1192, 1203, 1219, 1267, 1315, 1347, 1363, 1432, 1563, 1588, 1603, 1843, 1915, 1963, 2227, 2283, 2443, 2515, 2563, 2787, 2923, 3235, 3427, 3523, 3763
7	31	71, 151, 223, 251, 463, 467, 487, 587, 811, 827, 859, 1163, 1171, 1483, 1523, 1627, 1787, 1987, 2011, 2083, 2179, 2251, 2467, 2707, 3019, 3067, 3187, 3907, 4603, 5107, 5923

### Class Number Formula

A class number formula is a finite series giving exactly the CLASS NUMBER of a RING. For a RING of quadratic integers, the class number is denoted  $h(d)$ , where  $d$  is the discriminant. A class number formula is known for the full ring of cyclotomic integers, as well as for any subring of the cyclotomic integers. This formula includes the quadratic case as well as many cubic and higher-order rings.

see also CLASS NUMBER

### Class Representative

A set of class representatives is a SUBSET of  $X$  which contains exactly one element from each EQUIVALENCE CLASS.

### Class (Set)

A class is a special kind of SET invented to get around RUSSELL'S PARADOX while retaining the arbitrary criteria for membership which leads to difficulty for SETS. The members of classes are SETS, but it is possible to have the class  $C$  of "all SETS which are not members of themselves" without producing a paradox (since  $C$  is a proper class (and not a SET), it is not a candidate for membership in  $C$ ).

see also AGGREGATE, RUSSELL'S PARADOX, SET

### Classical Groups

The four following types of GROUPS,

1. LINEAR GROUPS,
2. ORTHOGONAL GROUPS,
3. SYMPLECTIC GROUPS, and
4. UNITARY GROUPS,

which were studied before more exotic types of groups (such as the SPORADIC GROUPS) were discovered.

see also GROUP, LINEAR GROUP, ORTHOGONAL GROUP, SYMPLECTIC GROUP, UNITARY GROUP

### Classification

The classification of a collection of objects generally means that a list has been constructed with exactly one member from each ISOMORPHISM type among the objects, and that tools and techniques can effectively be used to identify any combinatorially given object with its unique representative in the list. Examples of mathematical objects which have been classified include the finite SIMPLE GROUPS and 2-MANIFOLDS but not, for example, KNOTS.

### Classification Theorem

The classification theorem of FINITE SIMPLE GROUPS, also known as the ENORMOUS THEOREM, which states that the FINITE SIMPLE GROUPS can be classified completely into

1. CYCLIC GROUPS  $\mathbb{Z}_p$  of PRIME ORDER,
2. ALTERNATING GROUPS  $A_n$  of degree at least five,
3. LIE-TYPE CHEVALLEY GROUPS  $PSL(n, q)$ ,  $PSU(n, q)$ ,  $PsP(2n, q)$ , and  $P\Omega^e(n, q)$ ,
4. LIE-TYPE (TWISTED CHEVALLEY GROUPS or the TITS GROUP)  ${}^3D_4(q)$ ,  $E_6(q)$ ,  $E_7(q)$ ,  $E_8(q)$ ,  $F_4(q)$ ,  ${}^2F_4(2^n)'$ ,  $G_2(q)$ ,  ${}^2G_2(3^n)$ ,  ${}^2B(2^n)$ ,
5. SPORADIC GROUPS  $M_{11}$ ,  $M_{12}$ ,  $M_{22}$ ,  $M_{23}$ ,  $M_{24}$ ,  $J_2 = HJ$ ,  $Suz$ ,  $HS$ ,  $McL$ ,  $Co_3$ ,  $Co_2$ ,  $Co_1$ ,  $He$ ,  $Fi_{22}$ ,  $Fi_{23}$ ,  $Fi'_{24}$ ,  $HN$ ,  $Th$ ,  $B$ ,  $M$ ,  $J_1$ ,  $O'N$ ,  $J_3$ ,  $Ly$ ,  $Ru$ ,  $J_4$ .

The "PROOF" of this theorem is spread throughout the mathematical literature and is estimated to be approximately 15,000 pages in length.

### Clausen Formula

Clausen's  ${}_4F_3$  identity

$${}_4F_3 \left[ \begin{matrix} a & b & c & d \\ e & f & g \end{matrix} ; 1 \right] = \frac{(2a)_{|d|} (a+b)_{|d|} (2b)_{|d|}}{(2a+2b)_{|d|} a_{|d|} b_{|d|}},$$

holds for  $a+b+c-d=1/2$ ,  $e=a+b+1/2$ ,  $a+f=d+1=b+g$ ,  $d$  a nonpositive integer, and  $(a)_n$  is the POCHHAMMER SYMBOL (Petkovšek *et al.* 1996).

Another identity ascribed to Clausen which involves the HYPERGEOMETRIC FUNCTION  ${}_2F_1(a, b; c; z)$  and the GENERALIZED HYPERGEOMETRIC FUNCTION  ${}_3F_2(a, b, c; d, e; z)$  is given by

$$\left[ {}_2F_1 \left( \begin{matrix} a, b \\ a+b+\frac{1}{2} \end{matrix} ; x \right) \right]^2 = {}_3F_2 \left( \begin{matrix} 2a, a+b, 2b \\ a+b+\frac{1}{2}, 2a+2b \end{matrix} ; x \right).$$

## Clausen Function

Define

$$S_n(x) \equiv \sum_{k=1}^{\infty} \frac{\sin(kx)}{k^n} \quad (1)$$

$$C_n(x) \equiv \sum_{k=1}^{\infty} \frac{\cos(kx)}{k^n}, \quad (2)$$

and write

$$\text{Cl}_n(x) \equiv \begin{cases} S_n(x) = \sum_{k=1}^{\infty} \frac{\sin(kx)}{k^n} & n \text{ even} \\ C_n(x) = \sum_{k=1}^{\infty} \frac{\cos(kx)}{k^n} & n \text{ odd.} \end{cases} \quad (3)$$

Then the Clausen function  $\text{Cl}_n(x)$  can be given symbolically in terms of the POLYLOGARITHM as

$$\text{Cl}_n(x) = \begin{cases} \frac{1}{2}i[\text{Li}_n(e^{-ix}) - \text{Li}_n(e^{ix})] & n \text{ even} \\ \frac{1}{2}[\text{Li}_n(e^{-ix}) + \text{Li}_n(e^{ix})] & n \text{ odd.} \end{cases}$$

For  $n = 1$ , the function takes on the special form

$$\text{Cl}_1(x) = C_1(x) = -\ln |2 \sin(\frac{1}{2}x)| \quad (4)$$

and for  $n = 2$ , it becomes CLAUSEN'S INTEGRAL

$$\text{Cl}_2(x) = S_2(x) = -\int_0^x \ln[2 \sin(\frac{1}{2}t)] dt. \quad (5)$$

The symbolic sums of opposite parity are summable symbolically, and the first few are given by

$$C_2(x) = \frac{1}{6}\pi^2 - \frac{1}{2}\pi x + \frac{1}{4}x^2 \quad (6)$$

$$C_4(x) = \frac{1}{90} - \frac{1}{12}\pi^2 x^2 + \frac{1}{12}\pi x^3 - \frac{1}{48}x^4 \quad (7)$$

$$S_1(x) = \frac{1}{2}(\pi - x) \quad (8)$$

$$S_3(x) = \frac{1}{6}\pi^2 x - \frac{1}{4}\pi x^2 + \frac{1}{12}x^3 \quad (9)$$

$$S_5(x) = \frac{1}{90}\pi^4 x - \frac{1}{36}\pi^2 x^3 + \frac{1}{48}\pi x^4 - \frac{1}{240}x^5 \quad (10)$$

for  $0 \leq x \leq 2\pi$  (Abramowitz and Stegun 1972).

## CLEAN Algorithm

An iterative algorithm which DECONVOLVES a sampling function (the "DIRTY BEAM") from an observed brightness ("DIRTY MAP") of a radio source. This algorithm is of fundamental importance in radio astronomy, where it is used to create images of astronomical sources which are observed using arrays of radio telescopes ("synthesis imaging"). As a result of the algorithm's importance to synthesis imaging, a great deal of effort has gone into optimizing and adjusting the ALGORITHM. CLEAN is a nonlinear algorithm, since linear DECONVOLUTION algorithms such as WIENER FILTERING and inverse filtering

are inapplicable to applications with invisible distributions (i.e., incomplete sampling of the spatial frequency plane) such as map obtained in synthesis imaging.

The basic CLEAN method was developed by Högbom (1974). It was originally designed for point sources, but it has been found to work well for extended sources as well when given a reasonable starting model. The Högbom CLEAN constructs discrete approximations  $I_n$  to the CLEAN MAP in the  $(\xi, \eta)$  plane from the CONVOLUTION equation

$$b' * I = I', \quad (1)$$

where  $b'$  is the DIRTY BEAM,  $I'$  is the DIRTY MAP (both in the  $(\xi, \eta)$  PLANE), and  $f * g$  denotes a CONVOLUTION.

The CLEAN algorithm starts with an initial approximation  $I_0 = 0$ . At the  $n$ th iteration, it then searches for the largest value in the residual map

$$I_n = I' - b' * I_{n-1}. \quad (2)$$

A DELTA FUNCTION is then centered at the location of the largest residual flux and given an amplitude  $\mu$  (the so-called "LOOP GAIN") times this value. An antenna's response to the DELTA FUNCTION, the DIRTY BEAM, is then subtracted from  $I_{n-1}$  to yield  $I_n$ . Iteration continues until a specified iteration limit  $N$  is reached, or until the peak residual or ROOT-MEAN-SQUARE residual decreases to some level. The resulting final map is denoted  $I_N$ , and the position of each DELTA FUNCTION is saved in a "CLEAN component" table in the CLEAN MAP file. At the point where component subtraction is stopped, it is assumed that the residual brightness distribution consists mainly of NOISE.

To diminish high spatial frequency features which may be spuriously extrapolated from the measured data, each CLEAN component is convolved with the so-called CLEAN BEAM  $b$ , which is simply a suitably smoothed version of the sampling function ("DIRTY BEAM"). Usually, a GAUSSIAN is used. A good CLEAN BEAM should:

1. Have a unity FOURIER TRANSFORM inside the sampled region of  $(u, v)$  space,
2. Have a FOURIER TRANSFORM which tends to 0 outside the sampled  $(u, v)$  region as quickly as possible, and
3. Not have any effects produced by NEGATIVE side-lobes larger than the NOISE level.

A CLEAN MAP is produced when the final residual map is added to the approximate solution,

$$[\text{clean map}] = I_N * b + [I' - b' * I_N] \quad (3)$$

in order to include the NOISE.

CLEAN will always converge to one (of possibly many) solutions if the following three conditions are satisfied (Schwarz 1978):

1. The beam must be symmetric.
2. The FOURIER TRANSFORM of the DIRTY BEAM is NONNEGATIVE (positive definite or positive semidefinite).
3. There must be no spatial frequencies present in the dirty image which are not also present in the DIRTY BEAM.

These conditions are almost always satisfied in practice. If the number of CLEAN components does not exceed the number of independent  $(u, v)$  points, CLEAN converges to a solution which is the least squares fit of the FOURIER TRANSFORMS of the DELTA FUNCTION components to the measured visibility (Thompson *et al.* 1986, p. 347). Schwarz claims that the CLEAN algorithm is equivalent to a least squares fitting of cosine and sine parts in the  $(u, v)$  plane of the visibility data. Schwab has produced a NOISE analysis of the CLEAN algorithm in the case of least squares minimization of a noiseless image which involves an  $N \times M$  MATRIX. However, no NOISE analysis has been performed for a REAL image.

Poor modulation of short spacings results in an underestimation of the flux, which is manifested in a bowl of negative surface brightness surrounding an object. Providing an estimate of the "zero spacing" flux (the total flux of the source, which cannot be directly measured by an interferometer) can considerably reduce this effect. Modulations or stripes can occur at spatial frequencies corresponding to undersampled parts of the  $(u, v)$  plane. This can result in a golf ball-like mottling for disk sources such as planets, or a corrugated pattern of parallel lines of peaks and troughs ("stripes"). A more accurate model can be used to suppress the "golf ball" modulations, but may not eliminate the corrugations. A tapering function which deemphasizes data near  $(u, v) = (0, 0)$  can also be used. Stripes can sometimes be eliminated using the Cornwell smoothness-stabilized CLEAN (a.k.a. Prussian helmet algorithm; Thompson *et al.* 1986). CLEANing part way, then restarting the CLEAN also seems to eliminate the stripes, although this fact is more disturbing than reassuring. Stability of the CLEAN algorithm is discussed by Tan (1986).

In order to CLEAN a map of a given dimension, it is necessary to have a beam pattern twice as large so a point source can be subtracted from any point in the map. Because the CLEAN algorithm uses a FAST FOURIER TRANSFORM, the size must also be a POWER of 2.

There are many variants of the basic Högbom CLEAN which extend the method to achieve greater speed and produce more realistic maps. Alternate nonlinear DECONVOLUTION methods, such as the MAXIMUM ENTROPY METHOD, may also be used, but are generally slower than the CLEAN technique. The Astronomical Image Processing Software (AIPS) of the National Radio Astronomical Observatory includes 2-D

DECONVOLUTION algorithms in the tasks DCONV and UVMAP. Among the variants of the basic Högbom CLEAN are Clark, Cornwell smoothness stabilized (Prussian helmet), Cotton-Schwab, Gerchberg-Saxton (Fienup), Steer, Steer-Dewdney-Ito, and van Cittert iteration.

In the Clark (1980) modification, CLEAN picks out only the largest residual points, and subtracts approximate point source responses in the  $(\xi, \eta)$  plane during minor (Högbom CLEAN) cycles. It only occasionally (during major cycles) computes the full  $I_n$  residual map by subtracting the identified point source responses in the  $(u, v)$  plane using a FAST FOURIER TRANSFORM for the CONVOLUTION. The ALGORITHM then returns to a minor cycle. This algorithm modifies the Högbom method to take advantage of the array processor (although it also works without one). It is therefore a factor of 2–10 faster than the simple Högbom routine. It is implemented as the AIPS task **APCLN**.

The Cornwell smoothness stabilized variant was developed because, when dealing with two-dimensional extended structures, CLEAN can produce artifacts in the form of low-level high frequency stripes running through the brighter structure. These stripes derive from poor interpolations into unsampled or poorly sampled regions of the  $(u, v)$  plane. When dealing with quasi-one-dimensional sources (i.e., jets), the artifacts resemble knots (which may not be so readily recognized as spurious). **APCLN** can invoke a modification of CLEAN that is intended to bias it toward generating smoother solutions to the deconvolution problem while preserving the requirement that the transform of the CLEAN components list fits the data. The mechanism for introducing this bias is the addition to the DIRTY BEAM of a DELTA FUNCTION (or “spike”) of small amplitude (**PHAT**) while searching for the CLEAN components. The beam used for the deconvolution resembles the helmet worn by German military officers in World War I, hence the name “Prussian helmet” CLEAN.

The theory underlying the Cornwell smoothness stabilized algorithm is given by Cornwell (1982, 1983), where it is described as the smoothness stabilized CLEAN. It is implemented in the AIPS tasks **APCLN** and **MX**. The spike performs a NEGATIVE feedback into the dirty image, thus suppressing features not required by the data. Spike heights of a few percent and lower than usual loop gains are usually needed. Also according to the **MX** documentation,

$$\text{PHAT} \approx \frac{(\text{noise})^2}{2(\text{signal})^2} = \frac{1}{2(\text{SNR})^2}.$$

Unfortunately, the addition of a Prussian helmet generally has “limited success,” so resorting to another deconvolution method such as the MAXIMUM ENTROPY METHOD is sometimes required.

The Cotton-Schwab uses the Clark method, but the major cycle subtractions of CLEAN components are performed on ungridded visibility data. The Cotton-Schwab technique is often faster than the Clark variant. It is also capable of including the  $w$  baseline term, thus removing distortions from noncoplanar baselines. It is often faster than the Clark method. The Cotton-Schwab technique is implemented as the AIPS task **MX**.

The Gerchberg-Saxton variant, also called the Fienup variant, is a technique originally introduced for solving the phase problem in electron microscopy. It was subsequently adapted for visibility amplitude measurements only. A Gerchberg-Saxton map is constrained to be NONZERO, and positive. Data and image plane constraints are imposed alternately while transforming to and from the image plane. If the boxes to CLEAN are chosen to surround the source snugly, then the algorithm will converge faster and will have more chance of finding a unique image. The algorithm is slow, but should be comparable to the Clark technique (**APCLN**) if the map contains many picture elements. However, the resolution is data dependent and varies across the map. It is implemented as the AIPS task **APGS** (Pearson 1984).

The Steer variant is a modification of the Clark variant (Cornwell 1982). It is slow, but should be comparable to the Clark algorithm if the map contains many picture elements. The algorithm used in the program is due to David Steer. The principle is similar to Barry Clark’s CLEAN except that in the minor cycle only points above the (trim level)  $\times$  (peak in the residual map) are selected. In the major cycle these are removed using a FAST FOURIER TRANSFORM. If boxes are chosen to surround the source snugly, then the algorithm will converge faster and will have more chance of finding a unique image. It is implemented in AIPS as the experimental program **STEER** and as the Steer-Dewdney-Ito variant combined with the Clark algorithm as **SDCLN**.

The Steer-Dewdney-Ito variant is similar to the Clark variant, but the components are taken as all pixels having residual flux greater than a cutoff value times the current peak residual. This method should avoid the “ripples” produced by the standard CLEAN on extended emission. The AIPS task **SDCLN** does an AP-based CLEAN of the the Clark type, but differs from **APCLN** in that it offers the option to switch to the Steer-Dewdney-Ito method.

Finally, van Cittert iteration consists of two steps:

1. Estimate a correction to add to the current map estimate by multiplying the residuals by some weight. In the classical van Cittert algorithm, this weight is a constant, where as in CLEAN the weight is zero everywhere except at the peak of the residuals.
2. Add the step to the current estimate, and subtract the estimate, convolved with the DIRTY BEAM, from the residuals.

Though it is a simple algorithm, it works well (if slowly) for cases where the DIRTY BEAM is positive semidefinite (as it is in astronomical observations). The basic idea is that the DIRTY MAP is a reasonably good estimate of the deconvolved map. The different iterations vary only in the weight to apply to each residual in determining the correction step. van Cittert iteration is implemented as the AIPS task **APVC**, which is a rather experimental and ad hoc procedure. In some limiting cases, it reduces to the standard CLEAN algorithm (though it would be impractically slow).

### CLEAN Beam

An ELLIPTICAL GAUSSIAN fit to the DIRTY BEAM in order to remove sidelobes. The CLEAN beam is convolved with the final CLEAN iteration to diminish spurious high spatial frequencies.

see also CLEAN ALGORITHM, CLEAN MAP, DECONVOLUTION, DIRTY BEAM, DIRTY MAP

### CLEAN Map

The deconvolved map extracted from a finitely sampled DIRTY MAP by the CLEAN ALGORITHM, MAXIMUM ENTROPY METHOD, or any other DECONVOLUTION procedure.

see also CLEAN ALGORITHM, CLEAN BEAM, DECONVOLUTION, DIRTY BEAM, DIRTY MAP

### Clebsch-Aronhold Notation

A notation used to describe curves. The fundamental principle of Clebsch-Aronhold notation states that if each of a number of forms be replaced by a POWER of a linear form in the same number of variables equal to the order of the given form, and if a sufficient number of equivalent symbols are introduced by the ARONHOLD PROCESS so that no actual COEFFICIENT appears except to the first degree, then every identical relation holding for the new specialized forms holds for the general ones.

### References

- Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 79, 1959.

### Clebsch Diagonal Cubic

A CUBIC ALGEBRAIC SURFACE given by the equation

$$x_0^3 + x_1^3 + x_2^3 + x_3^3 + x_4^3 = 0, \quad (1)$$

with the added constraint

$$x_0 + x_1 + x_2 + x_3 + x_4 = 0. \quad (2)$$

The implicit equation obtained by taking the plane at infinity as  $x_0 + x_1 + x_2 + x_3/2$  is

$$\begin{aligned} 81(x^3 + y^3 + z^3) - 189(x^2y + x^2z + y^2x + y^2z + z^2x + z^2y) \\ + 54xyz + 126(xy + xz + yz) - 9(x^2 + y^2 + z^2) \\ - 9(x + y + z) + 1 = 0 \end{aligned} \quad (3)$$

(Hunt, Nordstrand). On Clebsch's diagonal surface, all 27 of the complex lines (SOLOMON'S SEAL LINES) present on a general smooth CUBIC SURFACE are real. In addition, there are 10 points on the surface where 3 of the 27 lines meet. These points are called ECKARDT POINTS (Fischer 1986, Hunt), and the Clebsch diagonal surface is the unique CUBIC SURFACE containing 10 such points (Hunt).

If one of the variables describing Clebsch's diagonal surface is dropped, leaving the equations

$$x_0^3 + x_1^3 + x_2^3 + x_3^3 = 0, \quad (4)$$

$$x_0 + x_1 + x_2 + x_3 = 0, \quad (5)$$

the equations degenerate into two intersecting PLANES given by the equation

$$(x + y)(x + z)(y + z) = 0. \quad (6)$$

see also CUBIC SURFACE, ECKARDT POINT

### Clebsch-Gordon Coefficient

A mathematical symbol used to integrate products of three SPHERICAL HARMONICS. Clebsch-Gordon coefficients commonly arise in applications involving the addition of angular momentum in quantum mechanics. If products of more than three SPHERICAL HARMONICS are desired, then a generalization known as WIGNER 6j-SYMBOLS or WIGNER 9j-SYMBOLS is used. The Clebsch-Gordon coefficients are written

$$C_{m_1 m_2}^j = (j_1 j_2 m_1 m_2 | j_1 j_2 j m) \quad (1)$$

and are defined by

$$\Psi_{JM} = \sum_{M=M_1+M_2} C_{M_1 M_2}^J \Psi_{M_1 M_2}, \quad (2)$$

where  $J \equiv J_1 + J_2$ . The Clebsch-Gordon coefficients are sometimes expressed using the related RACAH V-COEFFICIENTS

$$V(j_1 j_2 j; m_1 m_2 m) \quad (3)$$

or WIGNER 3j-SYMBOLS. Connections among the three are

$$(j_1 j_2 m_1 m_2 | j_1 j_2 j m) = (-1)^{-j_1+j_2-m} \sqrt{2j+1} \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} \quad (4)$$

$$(j_1 j_2 m_1 m_2 | j_1 j_2 j m) = (-1)^{j+m} \sqrt{2j+1} V(j_1 j_2 j; m_1 m_2 -m) \quad (5)$$

$$V(j_1 j_2 j; m_1 m_2 m) = (-1)^{-j_1+j_2+j} \begin{pmatrix} j_1 & j_2 & j_1 \\ m_2 & m_1 & m_2 \end{pmatrix}. \quad (6)$$

They have the symmetry

$$(j_1 j_2 m_1 m_2 | j_1 j_2 j m) = (-1)^{j_1+j_2-j} (j_2 j_1 m_2 m_1 | j_2 j_1 j m), \quad (7)$$

and obey the orthogonality relationships

$$\sum_{j,m} (j_1 j_2 m_1 m_2 | j_1 j_2 j m) (j_1 j_2 j m | j_1 j_2 m'_1 m'_2) = \delta_{m_1 m'_1} \delta_{m_2 m'_2} \quad (8)$$

$$\sum_{m_1, m_2} (j_1 j_2 m_1 m_2 | j_1 j_2 j m) (j_1 j_2 j' m' | j_1 j_2 m_1 m_2) = \delta_{jj'} \delta_{mm'}. \quad (9)$$

### Clement Matrix

see KAC MATRIX

### Clenshaw Recurrence Formula

The downward Clenshaw recurrence formula evaluates a sum of products of indexed COEFFICIENTS by functions which obey a recurrence relation. If

$$f(x) = \sum_{k=0}^N c_k F_k(x)$$

and

$$F_{n+1}(x) = \alpha(n, x) F_n(x) + \beta(n, x) F_{n-1}(x),$$

where the  $c_k$ s are known, then define

$$y_{N+2} = y_{N+1} = 0$$

$$y_k = \alpha(k, x)y_{k+1} + \beta(k+1, x)y_{k+2} + c_k$$

for  $k = N, N-1, \dots$  and solve backwards to obtain  $y_2$  and  $y_1$ .

$$c_k = y_k - \alpha(k, x)y_{k+1} - \beta(k+1, x)y_{k+2}$$

$$f(x) = \sum_{k=0}^N c_k F_k(x)$$

$$= c_0 F_0(x) + [y_1 - \alpha(1, x)y_2 - \beta(2, x)y_3]F_1(x)$$

$$+ [y_2 - \alpha(2, x)y_3 - \beta(3, x)y_4]F_2(x)$$

$$+ [y_3 - \alpha(3, x)y_4 - \beta(4, x)y_5]F_3(x)$$

$$+ [y_4 - \alpha(4, x)y_5 - \beta(5, x)y_6]F_4(x) + \dots$$

$$= c_0 F_0(x) + y_1 F_1(x) + y_2 [F_2(x) - \alpha(1, x)F_1(x)]$$

$$+ y_3 [F_3(x) - \alpha(2, x)F_2(x) - \beta(2, x)]$$

$$+ y_4 [F_4(x) - \alpha(3, x)F_3(x) - \beta(3, x)] + \dots$$

$$= c_0 F_0(x) + y_2 [\{\alpha(1, x)F_1(x) + \beta(1, x)F_0(x)\}$$

$$- \alpha(1, x)F_1(x)] + y_1 F_1(x)$$

$$= c_0 F_0(x) + y_1 F_1(x) + \beta(1, x)F_0(x)y_2.$$

The upward Clenshaw recurrence formula is

$$y_{-2} = y_{-1} = 0$$

$$y_k = \frac{1}{\beta(k+1, x)} [y_{k-2} - \alpha(k, x)y_{k-1} - c_k]$$

for  $k = 0, 1, \dots, N-1$ .

$$f(x) = c_N F_N(x) - \beta(N, x)F_{N-1}(x)y_{N-1} - F_N(x)y_{N-2}.$$

### Clifford's Circle Theorem

Let  $C_1, C_2, C_3$ , and  $C_4$  be four CIRCLES of GENERAL POSITION through a point  $P$ . Let  $P_{ij}$  be the second intersection of the CIRCLES  $C_i$  and  $C_j$ . Let  $C_{ijk}$  be the CIRCLE  $P_{ij}P_{ik}P_{jk}$ . Then the four CIRCLES  $P_{234}, P_{134}, P_{124}$ , and  $P_{123}$  all pass through the point  $P_{1234}$ . Similarly, let  $C_5$  be a fifth CIRCLE through  $P$ . Then the five points  $P_{2345}, P_{1345}, P_{1245}, P_{1235}$  and  $P_{1234}$  all lie on one CIRCLE  $C_{12345}$ . And so on.

see also CIRCLE, COX'S THEOREM

### Clifford's Curve Theorem

The dimension of a special series can never exceed half its order.

### References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 263, 1959.

### Clique

In a GRAPH of  $N$  VERTICES, a subset of pairwise adjacent VERTICES is known as a clique. A clique is a fully connected subgraph of a given graph. The problem of finding the size of a clique for a given GRAPH is an NP-COMplete PROBLEM. The number of graphs on  $n$  nodes having 3 cliques are 0, 0, 1, 4, 12, 31, 67, ... (Sloane's A005289).

**Close Packing**

see SPHERE PACKING

**Closed Curve**

*closed curves*

*open curves*

A CURVE with no endpoints which completely encloses an AREA. A closed curve is formally defined as the continuous IMAGE of a CLOSED SET.

see also SIMPLE CURVE

**Closed Curve Problem**

Find NECESSARY and SUFFICIENT conditions that determine when the integral curve of two periodic functions  $\kappa(s)$  and  $\tau(s)$  with the same period  $L$  is a CLOSED CURVE.

**Closed Disk**

An  $n$ -D closed disk of RADIUS  $r$  is the collection of points of distance  $\leq r$  from a fixed point in EUCLIDEAN  $n$ -space.

see also DISK, OPEN DISK

**Closed Form**

A discrete FUNCTION  $A(n, k)$  is called closed form (or sometimes “hypergeometric”) in two variables if the ratios  $A(n+1, k)/A(n, k)$  and  $A(n, k+1)/A(n, k)$  are both RATIONAL FUNCTIONS. A pair of closed form functions  $(F, G)$  is said to be a WILF-ZEILBERGER PAIR if

$$F(n+1, k) - F(n, k) = G(n, k+1) - G(n, k).$$

see also RATIONAL FUNCTION, WILF-ZEILBERGER PAIR

**References**

Petkovšek, M.; Wilf, H. S.; and Zeilberger, D. *A=B*. Wellesley, MA: A. K. Peters, p. 141, 1996.

**Closed Graph Theorem**

A linear OPERATOR between two BANACH SPACES is continuous IFF it has a “closed” GRAPH.

see also BANACH SPACE

**References**

Zeidler, E. *Applied Functional Analysis: Applications to Mathematical Physics*. New York: Springer-Verlag, 1995.

**Closed Interval**

An INTERVAL which includes its LIMIT POINTS. If the endpoints of the interval are FINITE numbers  $a$  and  $b$ , then the INTERVAL is denoted  $[a, b]$ . If one of the endpoints is  $\pm\infty$ , then the interval still contains all of its LIMIT POINTS, so  $[a, \infty)$  and  $(-\infty, b]$  are also closed intervals.

see also HALF-CLOSED INTERVAL, OPEN INTERVAL

**Closed Set**

There are several equivalent definitions of a closed SET. A SET  $S$  is closed if

1. The COMPLEMENT of  $S$  is an OPEN SET,
2.  $S$  is its own CLOSURE,
3. Sequences/nets/filters in  $S$  which converge do so within  $S$ ,
4. Every point outside  $S$  has a NEIGHBORHOOD disjoint from  $S$ .

The POINT-SET TOPOLOGICAL definition of a closed set is a set which contains all of its LIMIT POINTS. Therefore, a closed set  $C$  is one for which, whatever point  $x$  is picked outside of  $C$ ,  $x$  can always be isolated in some OPEN SET which doesn't touch  $C$ .

see also CLOSED INTERVAL

**Closure**

A SET  $S$  and a BINARY OPERATOR  $*$  are said to exhibit closure if applying the BINARY OPERATOR to two elements  $S$  returns a value which is itself a member of  $S$ .

The term “closure” is also used to refer to a “closed” version of a given set. The closure of a SET can be defined in several equivalent ways, including

1. The SET plus its LIMIT POINTS, also called “boundary” points, the union of which is also called the “frontier,”
2. The unique smallest CLOSED SET containing the given SET,
3. The COMPLEMENT of the interior of the COMPLEMENT of the set,
4. The collection of all points such that every NEIGHBORHOOD of them intersects the original SET in a nonempty SET.

In topologies where the T2-SEPARATION AXIOM is assumed, the closure of a finite SET  $S$  is  $S$  itself.

## Cluster Perimeter

The number of empty neighbors of a CLUSTER.

see also PERIMETER POLYNOMIAL

## Coanalytic Set

A DEFINABLE SET which is the complement of an ANALYTIC SET.

see also ANALYTIC SET

## Coastline Paradox

Determining the length of a country's coastline is not as simple as it first appears, as first considered by L. F. Richardson (1881–1953). In fact, the answer depends on the length of the RULER you use for the measurements. A shorter RULER measures more of the sinuosity of bays and inlets than a larger one, so the estimated length continues to increase as the RULER length decreases.

In fact, a coastline is an example of a FRACTAL, and plotting the length of the RULER versus the measured length of the coastline on a log-log plot gives a straight line, the slope of which is the FRACTAL DIMENSION of the coastline (and will be a number between 1 and 2).

**Cochleoid**

The cochleoid, whose name means “snail-form” in Latin, was first discussed by J. Peck in 1700 (MacTutor Archive). The points of contact of PARALLEL TANGENTS to the cochleoid lie on a STROPHOID.

In POLAR COORDINATES,

$$r = \frac{a \sin \theta}{\theta}. \quad (1)$$

In CARTESIAN COORDINATES,

$$(x^2 + y^2) \tan^{-1} \left( \frac{y}{x} \right) = ay. \quad (2)$$

The CURVATURE is

$$\kappa = \frac{2\sqrt{2} \theta^3 [2\theta - \sin(2\theta)]}{[1 + 2\theta^2 - \cos(2\theta) - 2\theta \sin(2\theta)]^{3/2}}. \quad (3)$$

### Cohomotopy Group

Cohomotopy groups are similar to HOMOTOPY GROUPS. A cohomotopy group is a GROUP related to the HOMOTOPY classes of MAPS from a SPACE  $X$  into a SPHERE  $S^n$ .

see also HOMOTOPY GROUP

### Coin

A flat disk which acts as a two-sided DIE.

see BERNOULLI TRIAL, CARDS, COIN PARADOX, COIN TOSSING, DICE, FELLER'S COIN-TOSSING CONSTANTS, FOUR COINS PROBLEM, GAMBLER'S RUIN

**Coin Problem**

Let there be  $n \geq 2$  INTEGERS  $0 < a_1 < \dots < a_n$  with  $(a_1, a_2, \dots, a_n) = 1$  (all RELATIVELY PRIME). For large enough  $N = \sum_{i=1}^n a_i x_i$ , there is a solution in NONNEGATIVE INTEGERS  $x_i$ . The greatest  $N = g(a_1, a_2, \dots, a_n)$  for which there is no solution is called the coin problem. Sylvester showed

$$g(a_1, a_2) = (a_1 - 1)(a_2 - 1) - 1,$$

and an explicit solution is known for  $n = 3$ , but no closed form solution is known for larger  $N$ .

**References**

Guy, R. K. "The Money-Changing Problem." §C7 in *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 113–114, 1994.

**Coin Tossing**

An idealized coin consists of a circular disk of zero thickness which, when thrown in the air and allowed to fall, will rest with either side face up ("heads" H or "tails" T) with equal probability. A coin is therefore a two-sided DIE. A coin toss corresponds to a BERNOULLI DISTRIBUTION with  $p = 1/2$ . Despite slight differences between the sides and NONZERO thickness of actual coins, the distribution of their tosses makes a good approximation to a  $p = 1/2$  BERNOULLI DISTRIBUTION.

There are, however, some rather counterintuitive properties of coin tossing. For example, it is twice as likely that the triple *TTH* will be encountered before *THT* than after it, and three times as likely that *THH* will precede *HTT*. Furthermore, it is six times as likely that *HTT* will be the first of *HTT*, *TTH*, and *TTT* to occur (Honsberger 1979). More amazingly still, *spinning* a penny instead of tossing it results in heads only about 30% of the time (Paulos 1995).

Let  $w(n)$  be the probability that no RUN of three consecutive heads appears in  $n$  independent tosses of a COIN. The following table gives the first few values of  $w(n)$ .

$n$	$w(n)$
0	1
1	1
2	1
3	$\frac{7}{8}$
4	$\frac{13}{16}$
5	$\frac{9}{4}$

Feller (1968, pp. 278–279) proved that

$$\lim_{n \rightarrow \infty} w(n) \alpha^{n+1} = \beta, \quad (1)$$

where

$$\alpha = \frac{1}{3}[(136 + 24\sqrt{33})^{1/3} - 8(136 + 24\sqrt{33})^{-1/3} - 2] \\ = 1.087378025 \dots \quad (2)$$

and

$$\beta = \frac{2 - \alpha}{4 - 3\alpha} = 1.236839845 \dots \quad (3)$$

The corresponding constants for a RUN of  $k > 1$  heads are  $\alpha_k$ , the smallest POSITIVE ROOT of

$$1 - x + (\tfrac{1}{2}x)^{k+1} = 0, \quad (4)$$

and

$$\beta_k = \frac{2 - \alpha}{k + 1 - k\alpha_k}. \quad (5)$$

These are modified for unfair coins with  $P(H) = p$  and  $P(T) = q = 1 - p$  to  $\alpha'_k$ , the smallest POSITIVE ROOT of

$$1 - x + qp^k x^{k+1} = 0, \quad (6)$$

and

$$\beta'_k = \frac{1 - p\alpha'_k}{(k + 1 - k\alpha'_k)p} \quad (7)$$

(Feller 1968, pp. 322–325).

### Colatitude

The polar angle on a SPHERE measured from the North Pole instead of the equator. The angle  $\phi$  in SPHERICAL COORDINATES is the COLATITUDE. It is related to the LATITUDE  $\delta$  by  $\phi = 90^\circ - \delta$ .

see also LATITUDE, LONGITUDE, SPHERICAL COORDINATES

### Colinear

see COLLINEAR

### Collatz Problem

A problem posed by L. Collatz in 1937, also called the  $3x + 1$  MAPPING, HASSE'S ALGORITHM, KAKUTANI'S PROBLEM, SYRACUSE ALGORITHM, SYRACUSE PROBLEM, THWAITES CONJECTURE, and ULAM'S PROBLEM (Lagarias 1985). Thwaites (1996) has offered a £1000 reward for resolving the CONJECTURE. Let  $n$  be an INTEGER. Then the Collatz problem asks if iterating

$$f(n) = \begin{cases} \frac{1}{2}n & \text{for } n \text{ even} \\ 3n + 1 & \text{for } n \text{ odd} \end{cases} \quad (1)$$

always returns to 1 for POSITIVE  $n$ . This question has been tested and found to be true for all numbers  $< 5.6 \times 10^{13}$  (Leavens and Vermeulen 1992), and more recently,  $10^{15}$  (Vardi 1991, p. 129). The members of the SEQUENCE produced by the Collatz are sometimes known as HAILSTONE NUMBERS. Because of the difficulty in solving this problem, Erdős commented that "mathematics is not yet ready for such problems" (Lagarias 1985). If NEGATIVE numbers are included, there are four known cycles (excluding the trivial 0 cycle): (4,

2, 1), (−2, −1), (−5, −7, −10), and (−17, −25, −37, −55, −82, −41, −61, −91, −136, −68, −34). The number of tripling steps needed to reach 1 for  $n = 1, 2, \dots$  are 0, 0, 2, 0, 1, 2, 5, 0, 6,  $\dots$  (Sloane's A006667).

The Collatz problem was modified by Terras (1976, 1979), who asked if iterating

$$T(x) = \begin{cases} \frac{1}{2}x & \text{for } x \text{ even} \\ \frac{1}{2}(3x + 1) & \text{for } x \text{ odd} \end{cases} \quad (2)$$

always returns to 1. If NEGATIVE numbers are included, there are 4 known cycles: (1, 2), (−1), (−5, −7, −10), and (−17, −25, −37, −55, −82, −41, −61, −91, −136, −68, −34). It is a special case of the "generalized Collatz problem" with  $d = 2$ ,  $m_0 = 1$ ,  $m_1 = 3$ ,  $r_0 = 0$ , and  $r_1 = -1$ . Terras (1976, 1979) also proved that the set of INTEGERS  $S_k \equiv \{n : n \text{ has stopping time } \leq k\}$  has a limiting asymptotic density  $F(k)$ , so the limit

$$F(k) = \lim_{x \rightarrow \infty} \frac{1}{x}, \quad (3)$$

for  $\{n : n \leq x \text{ and } \sigma(n) \leq k\}$  exists. Furthermore,  $F(k) \rightarrow 1$  as  $k \rightarrow \infty$ , so almost all INTEGERS have a finite stopping time. Finally, for all  $k \geq 1$ ,

$$1 - F(k) = \lim_{x \rightarrow \infty} \frac{1}{x} \leq 2^{-\eta k}, \quad (4)$$

where

$$\eta = 1 - H(\theta) = 0.05004 \dots \quad (5)$$

$$H(x) = -x \lg x - (1 - x) \lg(1 - x) \quad (6)$$

$$\theta = \frac{1}{\lg 3} \quad (7)$$

(Lagarias 1985).

Conway proved that the original Collatz problem has no nontrivial cycles of length  $< 400$ . Lagarias (1985) showed that there are no nontrivial cycles with length  $< 275,000$ . Conway (1972) also proved that Collatz-type problems can be formally UNDECIDABLE.

A generalization of the COLLATZ PROBLEM lets  $d \geq 2$  be a POSITIVE INTEGER and  $m_0, \dots, m_{d-1}$  be NONZERO INTEGERS. Also let  $r_i \in \mathbb{Z}$  satisfy

$$r_i \equiv im_i \pmod{d}. \quad (8)$$

Then

$$T(x) = \frac{m_i x - r_i}{d} \quad (9)$$

for  $x \equiv i \pmod{d}$  defines a generalized Collatz mapping. An equivalent form is

$$T(x) = \left\lfloor \frac{m_i x}{d} \right\rfloor + X_i \quad (10)$$

for  $x \equiv i \pmod{d}$  where  $X_0, \dots, X_{d-1}$  are INTEGERS and  $\lfloor r \rfloor$  is the FLOOR FUNCTION. The problem is connected with ERGODIC THEORY and MARKOV CHAINS (Matthews 1995). Matthews (1995) obtained the following table for the mapping

$$T_k(x) = \begin{cases} \frac{1}{2}x & \text{for } x \equiv 0 \pmod{2} \\ \frac{1}{2}(3x + k) & \text{for } x \equiv 1 \pmod{2}, \end{cases} \quad (11)$$

where  $k = T_{5^k}$ .

$k$	# Cycles	Max. Cycle Length
0	5	27
1	10	34
2	13	118
3	17	118
4	19	118
5	21	165
6	23	433

Matthews and Watts (1984) proposed the following conjectures.

1. If  $|m_0 \dots m_{d-1}| < d^d$ , then all trajectories  $\{T^K(n)\}$  for  $n \in \mathbb{Z}$  eventually cycle.
2. If  $|m_0 \dots m_{d-1}| > d^d$ , then almost all trajectories  $\{T^K(n)\}$  for  $n \in \mathbb{Z}$  are divergent, except for an exceptional set of INTEGERS  $n$  satisfying

$$\#\{n \in S \mid -X \leq n < X\} = o(X).$$

3. The number of cycles is finite.
4. If the trajectory  $\{T^K(n)\}$  for  $n \in \mathbb{Z}$  is not eventually cyclic, then the iterates are uniformly distribution mod  $d^\alpha$  for each  $\alpha \geq 1$ , with

$$\lim_{N \rightarrow \infty} \frac{1}{N+1} \text{card}\{K \leq N \mid T^K(n) \equiv j \pmod{d^\alpha}\} = d^{-\alpha} \quad (12)$$

for  $0 \leq j \leq d^\alpha - 1$ .

Matthews believes that the map

$$T(x) = \begin{cases} 7x + 3 & \text{for } x \equiv 0 \pmod{3} \\ \frac{1}{3}(7x + 2) & \text{for } x \equiv 1 \pmod{3} \\ \frac{1}{3}(x - 2) & \text{for } x \equiv 2 \pmod{3} \end{cases} \quad (13)$$

will either reach  $0 \pmod{3}$  or will enter one of the cycles  $(-1)$  or  $(-2, -4)$ , and offers a \$100 (Australian?) prize for a proof.

#### Collinear

Three or more points  $P_1, P_2, P_3, \dots$ , are said to be collinear if they lie on a single straight LINE  $L$ . (Two points are always collinear.) This will be true IFF the ratios of distances satisfy

$$x_2 - x_1 : y_2 - y_1 : z_2 - z_1 = x_3 - x_1 : y_3 - y_1 : z_3 - z_1.$$

Two points are trivially collinear since two points determine a LINE.

see also CONCYCLIC, DIRECTED ANGLE, N-CLUSTER, SYLVESTER'S LINE PROBLEM

#### Collineation

A transformation of the plane which transforms COLLINEAR points into COLLINEAR points. A projective collineation transforms every 1-D form projectively, and a perspective collineation is a collineation which leaves all lines through a point and points through a line invariant. In an ELATION, the center and axis are incident; in

a HOMOLOGY they are not. For further discussion, see Coxeter (1969, p. 248).

see also AFFINITY, CORRELATION, ELATION, EQUI-AFFINITY, HOMOLOGY (GEOMETRY), PERSPECTIVE COLLINEATION, PROJECTIVE COLLINEATION

#### References

Coxeter, H. S. M. "Collineations and Correlations." §14.6 in *Introduction to Geometry*, 2nd ed. New York: Wiley, pp. 247–251, 1969.

### Cologarithm

The LOGARITHM of the RECIPROCAL of a number, equal to the NEGATIVE of the LOGARITHM of the number itself,

$$\text{colog } x \equiv \log \left( \frac{1}{x} \right) = -\log x.$$

see also ANTILOGARITHM, LOGARITHM

### Colon Product

Let **AB** and **CD** be DYADS. Their colon product is defined by

$$\mathbf{AB} : \mathbf{CD} \equiv \mathbf{C} \cdot \mathbf{AB} \cdot \mathbf{D} = (\mathbf{A} \cdot \mathbf{C})(\mathbf{B} \cdot \mathbf{D}).$$

### Colorable

Color each segment of a KNOT DIAGRAM using one of three colors. If

1. at any crossing, either the colors are all different or all the same, and
2. at least two colors are used,

then a KNOT is said to be colorable (or more specifically, THREE-COLORABLE). Colorability is invariant under REIDEMEISTER MOVES, and can be generalized. For instance, for five colors 0, 1, 2, 3, and 4, a KNOT is five-colorable if

1. at any crossing, three segments meet. If the overpass is numbered  $a$  and the two underpasses  $B$  and  $C$ , then  $2a \equiv b + c \pmod{5}$ , and
2. at least two colors are used.

Colorability cannot always distinguish HANDEDNESS. For instance, three-colorability can distinguish the mirror images of the TREFOIL KNOT but not the FIGURE-OF-EIGHT KNOT. Five-colorability, on the other hand, distinguishes the MIRROR IMAGES of the FIGURE-OF-EIGHT KNOT but not the TREFOIL KNOT.

see also COLORING, THREE-COLORABLE

### Coloring

A coloring of plane regions, LINK segments, etc., is an assignment of a distinct labelling (which could be a number, letter, color, etc.) to each component. Coloring problems generally involve TOPOLOGICAL considerations (i.e., they depend on the abstract study of the arrangement of objects), and theorems about colorings,

such as the famous FOUR-COLOR THEOREM, can be extremely difficult to prove.

**Combination Lock**

Let a combination of  $n$  buttons be a SEQUENCE of disjoint nonempty SUBSETS of the SET  $\{1, 2, \dots, n\}$ . If the number of possible combinations is denoted  $a_n$ , then  $a_n$  satisfies the RECURRENCE RELATION

$$a_n = \sum_{i=0}^{n-1} \binom{n}{n-i} a_i, \quad (1)$$

with  $a_0 = 1$ . This can also be written

$$a_n = \frac{d^n}{dx^n} \left( \frac{1}{2 - e^x} \right) \Big|_{x=0} = \frac{1}{2} \sum_{k=0}^{\infty} \frac{k^n}{2^k}, \quad (2)$$

where the definition  $0^0 = 1$  has been used. Furthermore,

$$a_n = \sum_{k=1}^n A_{n,k} 2^{n-k} = \sum_{k=1}^n A_{n,k} 2^{k-1}, \quad (3)$$

where  $A_{n,k}$  are EULERIAN NUMBERS. In terms of the STIRLING NUMBERS OF THE SECOND KIND  $s(n, k)$ ,

$$a_n = \sum_{k=1}^n k! s(n, k). \quad (4)$$

$a_n$  can also be given in closed form as

$$a_n = \frac{1}{2} \text{Li}_{-n}\left(\frac{1}{2}\right), \quad (5)$$

where  $\text{Li}_n(z)$  is the POLYLOGARITHM. The first few values of  $a_n$  for  $n = 1, 2, \dots$  are 1, 3, 13, 75, 541, 4683, 47293, 545835, 7087261, 102247563, ... (Sloane's A000670).

The quantity

$$b_n \equiv \frac{a_n}{n!} \quad (6)$$

satisfies the inequality

$$\frac{1}{2(\ln 2)^n} \leq b_n \leq \frac{1}{(\ln 2)^n}. \quad (7)$$

## Comma Derivative

$$A_{,k} \equiv \frac{\partial A}{\partial x^k} \equiv \partial_k A$$

$$A^k_{,k} \equiv \frac{1}{g_k} \frac{\partial A^k}{\partial x^k} \equiv \partial_k A^k.$$

see also COVARIANT DERIVATIVE, SEMICOLON DERIVATIVE

## Comma of Didymus

The musical interval by which four fifths exceed a seventeenth (i.e., two octaves and a major third),

$$\frac{\left(\frac{3}{2}\right)^4}{2^2\left(\frac{5}{4}\right)} = \frac{3^4}{2^4 \cdot 5} = \frac{81}{80} = 1.0125,$$

also called a SYNTONIC COMMA.

see also COMMA OF PYTHAGORAS, DIESIS, SCHISMA

## Comma of Pythagoras

The musical interval by which twelve fifths exceed seven octaves,

$$\frac{\left(\frac{3}{2}\right)^{12}}{2^7} = \frac{3^{12}}{2^{19}} = \frac{531441}{524288} = 1.013643265.$$

Successive CONTINUED FRACTION CONVERGENTS to  $\log 2 / \log(3/2)$  give increasingly close approximations  $m/n$  of  $m$  fifths by  $n$  octaves as 1, 2, 5/3, 12/7, 41/24, 53/31, 306/179, 665/389, ... (Sloane's A005664 and A046102; Jeans 1968, p. 188), shown in **bold** in the table below. All near-equalities of  $m$  fifths and  $n$  octaves having

$$R \equiv \frac{\left(\frac{3}{2}\right)^m}{2^n} = \frac{3^m}{2^{m+n}}$$

with  $|R - 1| < 0.02$  are given in the following table.

$m$	$n$	Ratio	$m$	$n$	Ratio
<b>12</b>	<b>7</b>	1.013643265	265	155	1.010495356

## Common Cycloid

see CYCLOID

## Common Residue

The value of  $b$ , where  $a \equiv b \pmod{m}$ , taken to be NON-NEGATIVE and smaller than  $m$ .

see also MINIMAL RESIDUE, RESIDUE (CONGRUENCE)

## Commutation Coefficient

A coefficient which gives the difference between partial derivatives of two coordinates with respect to the other coordinate,

$$c_{\alpha\beta}^{\mu} \vec{e}_{\mu} = [\vec{e}_{\alpha}, \vec{e}_{\beta}] = \nabla_{\alpha} \vec{e}_{\beta} - \nabla_{\beta} \vec{e}_{\alpha}.$$

see also CONNECTION COEFFICIENT

**Commutative**

Let  $A$  denote an  $\mathbb{R}$ -algebra, so that  $A$  is a VECTOR SPACE over  $\mathbb{R}$  and

$$\begin{aligned} A \times A &\rightarrow A \\ (x, y) &\mapsto x \cdot y. \end{aligned}$$

Now define

$$Z \equiv \{x \in A : x \cdot y \text{ for some } y \in A \neq 0\},$$

where  $0 \in Z$ . An ASSOCIATIVE  $\mathbb{R}$ -algebra is commutative if  $x \cdot y = y \cdot x$  for all  $x, y \in A$ . Similarly, a RING is commutative if the MULTIPLICATION operation is commutative, and a LIE ALGEBRA is commutative if the COMMUTATOR  $[A, B]$  is 0 for every  $A$  and  $B$  in the LIE ALGEBRA.

see also ABELIAN, ASSOCIATIVE, TRANSITIVE

Cox, D.; Little, J.; and O'Shea, D. *Ideals, Varieties, and Algorithms: An Introduction to Algebraic Geometry and Commutative Algebra*, 2nd ed. New York: Springer-Verlag, 1996.  
Samuel, P. and Zariski, O. *Commutative Algebra*, Vol. 2. New York: Springer-Verlag, 1997.

**Commutator**

Let  $\tilde{A}, \tilde{B}, \dots$  be OPERATORS. Then the commutator of  $\tilde{A}$  and  $\tilde{B}$  is defined as

$$[\tilde{A}, \tilde{B}] \equiv \tilde{A}\tilde{B} - \tilde{B}\tilde{A}. \quad (1)$$

Let  $a, b, \dots$  be constants. Identities include

$$[f(x), x] = 0 \quad (2)$$

$$[\tilde{A}, \tilde{A}] = 0 \quad (3)$$

$$[\tilde{A}, \tilde{B}] = -[\tilde{B}, \tilde{A}] \quad (4)$$

$$[\tilde{A}, \tilde{B}\tilde{C}] = [\tilde{A}, \tilde{B}]\tilde{C} + \tilde{B}[\tilde{A}, \tilde{C}] \quad (5)$$

$$[\tilde{A}\tilde{B}, \tilde{C}] = [\tilde{A}, \tilde{C}]\tilde{B} + \tilde{A}[\tilde{B}, \tilde{C}] \quad (6)$$

$$[a + \tilde{A}, b + \tilde{B}] = [\tilde{A}, \tilde{B}] \quad (7)$$

$$[\tilde{A} + \tilde{B}, \tilde{C} + \tilde{D}] = [\tilde{A}, \tilde{C}] + [\tilde{A}, \tilde{D}] + [\tilde{B}, \tilde{C}] + [\tilde{B}, \tilde{D}]. \quad (8)$$

The commutator can be interpreted as the "infinitesimal" of the commutator of a LIE GROUP.

Let  $A$  and  $B$  be TENSORS. Then

$$[A, B] \equiv \nabla_A B - \nabla_B A. \quad (9)$$

see also ANTICOMMUTATOR, JACOBI IDENTITIES

**Compact Group**

If the parameters of a LIE GROUP vary over a CLOSED INTERVAL, the GROUP is compact. Every representation of a compact group is equivalent to a UNITARY representation.

**Compact Manifold**

A MANIFOLD which can be "charted" with finitely many EUCLIDEAN SPACE charts. The CIRCLE is the only compact 1-D MANIFOLD. The SPHERE and  $n$ -TORUS are the only compact 2-D MANIFOLDS. It is an open question if the known compact MANIFOLDS in 3-D are complete, and it is not even known what a complete list in 4-D should look like. The following terse table therefore summarizes current knowledge about the number of compact manifolds  $N(D)$  of  $D$  dimensions.

$D$	$N(D)$
1	1
2	2

see also TYCHONOF COMPACTNESS THEOREM

**Compact Set**

The SET  $S$  is compact if, from any SEQUENCE of elements  $X_1, X_2, \dots$  of  $S$ , a subsequence can always be extracted which tends to some limit element  $X$  of  $S$ . Compact sets are therefore closed and bounded.

**Compact Space**

A TOPOLOGICAL SPACE is compact if every open cover of  $X$  has a finite subcover. In other words, if  $X$  is the union of a family of open sets, there is a finite subfamily whose union is  $X$ . A subset  $A$  of a TOPOLOGICAL SPACE  $X$  is compact if it is compact as a TOPOLOGICAL SPACE with the relative topology (i.e., every family of open sets of  $X$  whose union contains  $A$  has a finite subfamily whose union contains  $A$ ).

**Compact Surface**

A surface with a finite number of TRIANGLES in its TRIANGULATION. The SPHERE and TORUS are compact, but the PLANE and TORUS minus a DISK are not.

**Compactness Theorem**

Inside a BALL  $B$  in  $\mathbb{R}^3$ ,

$$\{ \text{rectifiable currents } S \text{ in } BL \text{ AREA } S \leq c, \text{ length } \partial S \leq c \}$$

is compact under the FLAT NORM.

**References**

- Morgan, F. "What Is a Surface?" *Amer. Math. Monthly* **103**, 369–376, 1996.

**Companion Knot**

Let  $K_1$  be a knot inside a TORUS. Now knot the TORUS in the shape of a second knot (called the companion knot)  $K_2$ . Then the new knot resulting from  $K_1$  is called the SATELLITE KNOT  $K_3$ .

References

Adams, C. C. *The Knot Book: An Elementary Introduction to the Mathematical Theory of Knots*. New York: W. H. Freeman, pp. 115–118, 1994.

**Comparability Graph**

The comparability graph of a POSET  $P = (X, \leq)$  is the GRAPH with vertex set  $X$  for which vertices  $x$  and  $y$  are adjacent IFF either  $x \leq y$  or  $y \leq x$  in  $P$ .

see also INTERVAL GRAPH, PARTIALLY ORDERED SET

**Comparison Test**

Let  $\sum a_k$  and  $\sum b_k$  be a SERIES with POSITIVE terms and suppose  $a_1 \leq b_1$ ,  $a_2 \leq b_2$ , ...

1. If the bigger series CONVERGES, then the smaller series also CONVERGES.
2. If the smaller series DIVERGES, then the bigger series also DIVERGES.

see also CONVERGENCE TESTS

References

Arfken, G. *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 280–281, 1985.

**Compass**

A tool with two arms joined at their ends which can be used to draw CIRCLES. In GEOMETRIC CONSTRUCTIONS, the classical Greek rules stipulate that the compass cannot be used to mark off distances, so it must “collapse” whenever one of its arms is removed from the page. This results in significant complication in the complexity of GEOMETRIC CONSTRUCTIONS.

see also CONSTRUCTIBLE POLYGON, GEOMETRIC CONSTRUCTION, GEOMETROGRAPHY, MASCHERONI CONSTRUCTION, PLANE GEOMETRY, POLYGON, PONCELET-STEINER THEOREM, RULER, SIMPLICITY, STEINER CONSTRUCTION, STRAIGHTEDGE

References

Dixon, R. “Compass Drawings.” Ch. 1 in *Mathographics*. New York: Dover, pp. 1–78, 1991.

**Compatible**

Let  $\|A\|$  be the MATRIX NORM associated with the MATRIX  $A$  and  $\|x\|$  be the VECTOR NORM associated with a VECTOR  $x$ . Let the product  $Ax$  be defined, then  $\|A\|$  and  $\|x\|$  are said to be compatible if

$$\|Ax\| \leq \|A\| \|x\|.$$

References

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products*, 5th ed. San Diego, CA: Academic Press, p. 1115, 1980.

**Complement Graph**

The complement GRAPH  $\bar{G}$  of  $G$  has the same VERTICES as  $G$  but contains precisely those two-element SUBSETS which are not in  $G$ .

**Complement Knot**

see KNOT COMPLEMENT

**Complement Set**

Given a set  $S$  with a subset  $E$ , the complement of  $E$  is defined as

$$E' \equiv \{F : F \in S, F \notin E\}. \quad (1)$$

If  $E = S$ , then

$$E' \equiv S' = \emptyset, \quad (2)$$

where  $\emptyset$  is the EMPTY SET. Given a single SET, the second PROBABILITY AXIOM gives

$$1 = P(S) = P(E \cup E'). \quad (3)$$

Using the fact that  $E \cap E' = \emptyset$ ,

$$1 = P(E) + P(E') \quad (4)$$

$$P(E') = 1 - P(E). \quad (5)$$

This demonstrates that

$$P(S') = P(\emptyset) = 1 - P(S) = 1 - 1 = 0. \quad (6)$$

Given two SETS,

$$P(E \cap F') = P(E) - P(E \cap F) \quad (7)$$

$$P(E' \cap F') = 1 - P(E) - P(F) + P(E \cap F). \quad (8)$$

**Complementary Angle**

Two ANGLES  $\alpha$  and  $\pi/2 - \alpha$  are said to be complementary.

see also ANGLE, SUPPLEMENTARY ANGLE

**Complete**

see COMPLETE AXIOMATIC THEORY, COMPLETE BGRAPH, COMPLETE FUNCTIONS, COMPLETE GRAPH, COMPLETE QUADRANGLE, COMPLETE QUADRILATERAL, COMPLETE SEQUENCE, COMPLETE SPACE, COMPLETENESS PROPERTY, WEAKLY COMPLETE SEQUENCE

**Complete Axiomatic Theory**

An axiomatic theory (such as a GEOMETRY) is said to be complete if each valid statement in the theory is capable of being proven true or false.

see also CONSISTENCY

## Complete Bigraph

see COMPLETE BIPARTITE GRAPH

## Complete Bipartite Graph

A BIPARTITE GRAPH (i.e., a set of VERTICES decomposed into two disjoint sets such that there are no two VERTICES within the same set are adjacent) such that every pair of VERTICES in the two sets are adjacent. If there are  $p$  and  $q$  VERTICES in the two sets, the complete bipartite graph (sometimes also called a COMPLETE BIGRAPH) is denoted  $K_{p,q}$ . The above figures show  $K_{3,2}$  and  $K_{2,5}$ .

see also BIPARTITE GRAPH, COMPLETE GRAPH, COMPLETE  $k$ -PARTITE GRAPH,  $k$ -PARTITE GRAPH, THOMASSEN GRAPH, UTILITY GRAPH

## References

Saaty, T. L. and Kainen, P. C. *The Four-Color Problem: Assaults and Conquest*. New York: Dover, p. 12, 1986.

## Complete Functions

A set of ORTHONORMAL FUNCTIONS  $\phi_n(x)$  is termed complete in the CLOSED INTERVAL  $x \in [a, b]$  if, for every piecewise CONTINUOUS FUNCTION  $f(x)$  in the interval, the minimum square error

$$E_n \equiv \|f - (c_1\phi_1 + \dots + c_n\phi_n)\|^2$$

(where  $\|$  denotes the NORM) converges to zero as  $n$  becomes infinite. Symbolically, a set of functions is complete if

$$\lim_{m \rightarrow \infty} \int_a^b \left[ f(x) - \sum_{n=0}^m a_n \phi_n(x) \right]^2 w(x) dx = 0,$$

where  $w(x)$  is a WEIGHTING FUNCTION and the above is a LEBESGUE INTEGRAL.

see also BESSEL'S INEQUALITY, HILBERT SPACE

## References

Arfken, G. "Completeness of Eigenfunctions." §9.4 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 523–538, 1985.

## Complete Graph

A GRAPH in which each pair of VERTICES is connected by an EDGE. The complete graph with  $n$  VERTICES is denoted  $K_n$ . In older literature, complete GRAPHS are called UNIVERSAL GRAPHS.

$K_4$  is the TETRAHEDRAL GRAPH and is therefore a PLANAR GRAPH.  $K_5$  is nonplanar. Conway and Gordon (1983) proved that every embedding of  $K_6$  is INTRINSICALLY LINKED with at least one pair of linked triangles. They also showed that any embedding of  $K_7$  contains a knotted HAMILTONIAN CYCLE.

The number of EDGES in  $K_v$  is  $v(v-1)/2$ , and the GENUS is  $(v-3)(v-4)/12$  for  $v \geq 3$ . The number of distinct variations for  $K_n$  (GRAPHS which cannot be transformed into each other without passing nodes through an EDGE or another node) for  $n = 1, 2, \dots$  are 1, 1, 1, 1, 6, 3, 411, 37, .... The ADJACENCY MATRIX of the complete graph takes the particularly simple form of all 1s with 0s on the diagonal.

It is not known in general if a set of TREES with 1, 2, ...,  $n-1$  EDGES can always be packed into  $K_n$ . However, if the choice of TREES is restricted to either the path or star from each family, then the packing can always be done (Zaks and Liu 1977, Honsberger 1985).

**Complete  $k$ -Partite Graph**

A  $k$ -PARTITE GRAPH (i.e., a set of VERTICES decomposed into  $k$  disjoint sets such that no two VERTICES within the same set are adjacent) such that every pair of VERTICES in the  $k$  sets are adjacent. If there are  $p, q, \dots, r$  VERTICES in the  $k$  sets, the complete  $k$ -partite graph is denoted  $K_{p,q,\dots,r}$ . The above figure shows  $K_{2,3,5}$ .

see also COMPLETE GRAPH, COMPLETE  $k$ -PARTITE GRAPH,  $k$ -PARTITE GRAPH

**References**

Saaty, T. L. and Kainen, P. C. *The Four-Color Problem: Assaults and Conquest*. New York: Dover, p. 12, 1986.

**Complete Metric Space**

A complete metric space is a METRIC SPACE in which every CAUCHY SEQUENCE is CONVERGENT. Examples include the REAL NUMBERS with the usual metric and the  $p$ -ADIC NUMBERS.

**Complete Permutation**

see DERANGEMENT

**Complete Quadrangle**

If the four points making up a QUADRILATERAL are joined pairwise by six distinct lines, a figure known as a complete quadrangle results. Note that a complete quadrilateral is defined differently from a COMPLETE QUADRANGLE.

The midpoints of the sides of any complete quadrangle and the three diagonal points all lie on a CONIC known as the NINE-POINT CONIC. If it is an ORTHOCENTRIC QUADRILATERAL, the CONIC reduces to a CIRCLE. The ORTHOCENTERS of the four TRIANGLES of a complete quadrangle are COLLINEAR on the RADICAL LINE of the CIRCLES on the diameters of a QUADRILATERAL.

Ogilvy, C. S. *Excursions in Geometry*. New York: Dover, pp. 101–104, 1990.

**Complete Quadrilateral**

The figure determined by four lines and their six points of intersection (Johnson 1929, pp. 61–62). Note that this is different from a COMPLETE QUADRANGLE. The midpoints of the diagonals of a complete quadrilateral are COLLINEAR (Johnson 1929, pp. 152–153).

A theorem due to Steiner (Mention 1862, Johnson 1929, Steiner 1971) states that in a complete quadrilateral, the bisectors of angles are CONCURRENT at 16 points which are the incenters and EXCENTERS of the four TRIANGLES. Furthermore, these points are the intersections of two sets of four CIRCLES each of which is a member of a conjugate coaxial system. The axes of these systems intersect at the point common to the CIRCUMCIRCLES of the quadrilateral.

Steiner, J. *Gesammelte Werke*, 2nd ed, Vol. 1. New York: Chelsea, p. 223, 1971.

**Complete Residue System**

A set of numbers  $a_0, a_1, \dots, a_{m-1} \pmod{m}$  form a complete set of residues if they satisfy

$$a_i \equiv i \pmod{m}$$

for  $i = 0, 1, \dots, m-1$ . In other words, a complete system of residues is formed by a base and a modulus if the residues  $r_i$  in  $b^i \equiv r_i \pmod{m}$  for  $i = 1, \dots, m-1$  run through the values  $1, 2, \dots, m-1$ .

see also HAUPT-EXPONENT

**Complete Sequence**

A SEQUENCE of numbers  $V = \{\nu_n\}$  is complete if every POSITIVE INTEGER  $n$  is the sum of some subsequence of  $V$ , i.e., there exist  $a_i = 0$  or  $1$  such that

$$n = \sum_{i=1}^{\infty} a_i \nu_i$$

(Honsberger 1985, pp. 123–126). The FIBONACCI NUMBERS are complete. In fact, dropping one number still

leaves a complete sequence, although dropping two numbers does not (Honsberger 1985, pp. 123 and 126). The SEQUENCE of PRIMES with the element {1} prepended,

$$\{1, 2, 3, 5, 7, 11, 13, 17, 19, 23, \dots\}$$

is complete, even if any number of PRIMES each  $> 7$  are dropped, as long as the dropped terms do not include two consecutive PRIMES (Honsberger 1985, pp. 127–128). This is a consequence of BERTRAND'S POSTULATE.

### Complete Space

A SPACE of COMPLETE FUNCTIONS.

see also COMPLETE METRIC SPACE

### Completely Regular Graph

A POLYHEDRAL GRAPH is completely regular if the DUAL GRAPH is also REGULAR. There are only five types. Let  $\rho$  be the number of EDGES at each node,  $\rho^*$  the number of EDGES at each node of the DUAL GRAPH,  $V$  the number of VERTICES,  $E$  the number of EDGES, and  $F$  the number of faces in the PLATONIC SOLID corresponding to the given graph. The following table summarizes the completely regular graphs.

Type	$\rho$	$\rho^*$	$V$	$E$	$F$
Tetrahedral	3	3	4	6	4
Cubical	3	4	8	12	6
Dodecahedral	3	5	20	39	12
Octahedral	4	3	6	12	8
Icosahedral	5	3	12	30	20

### Completeness Property

All lengths can be expressed as REAL NUMBERS.

### Completing the Square

The conversion of an equation of the form  $ax^2 + bx + c$  to the form

$$a \left( x + \frac{b}{2a} \right)^2 + \left( c - \frac{b^2}{4a} \right),$$

which, defining  $B \equiv b/2a$  and  $C \equiv c - b^2/4a$ , simplifies to

$$a(x + B)^2 + C.$$

### Complex

A finite SET of SIMPLEXES such that no two have a common point. A 1-D complex is called a GRAPH.

see also CW-COMPLEX, SIMPLICIAL COMPLEX

### Complex Analysis

The study of COMPLEX NUMBERS, their DERIVATIVES, manipulation, and other properties. Complex analysis is an extremely powerful tool with an unexpectedly large number of practical applications to the solution of physical problems. CONTOUR INTEGRATION, for example, provides a method of computing difficult INTEGRALS by investigating the singularities of the function in regions of the COMPLEX PLANE near and between the limits of integration.

The most fundamental result of complex analysis is the CAUCHY-RIEMANN EQUATIONS, which give the conditions a FUNCTION must satisfy in order for a complex generalization of the DERIVATIVE, the so-called COMPLEX DERIVATIVE, to exist. When the COMPLEX DERIVATIVE is defined "everywhere," the function is said to be ANALYTIC. A single example of the unexpected power of complex analysis is PICARD'S THEOREM, which states that an ANALYTIC FUNCTION assumes every COMPLEX NUMBER, with possibly one exception, infinitely often in any NEIGHBORHOOD of an ESSENTIAL SINGULARITY!

**Complex Conjugate**

The complex conjugate of a COMPLEX NUMBER  $z \equiv a+bi$  is defined to be  $z^* \equiv a-bi$ . The complex conjugate is ASSOCIATIVE,  $(z_1 + z_2)^* = z_1^* + z_2^*$ , since

$$\begin{aligned}(a_1 + b_1i)^* + (a_2 + b_2i)^* &= a_1 - ib_1 + a_2 - ib_2 \\ &= (a_1 - ib_1) + (a_2 - ib_2) \\ &= (a_1 + b_1)^* + (a_2 + b_2)^*,\end{aligned}$$

and DISTRIBUTIVE,  $(z_1 z_2)^* = z_1^* z_2^*$ , since

$$\begin{aligned}[(a_1 + b_1i)(a_2 + b_2i)]^* &= [(a_1 a_2 - b_1 b_2) + i(a_1 b_2 + a_2 b_1)]^* \\ &= (a_1 a_2 - b_1 b_2) - i(a_1 b_2 + a_2 b_1) \\ &= (a_1 - ib_1)(a_2 - ib_2) \\ &= (a_1 + ib_1)^*(a_2 + ib_2)^*.\end{aligned}$$

**References**

**Complex Derivative**

A DERIVATIVE of a COMPLEX function, which must satisfy the CAUCHY-RIEMANN EQUATIONS in order to be COMPLEX DIFFERENTIABLE.

see also CAUCHY-RIEMANN EQUATIONS, COMPLEX DIFFERENTIABLE, DERIVATIVE

**Complex Differentiable**

If the CAUCHY-RIEMANN EQUATIONS are satisfied for a function  $f(x) = u(x) + iv(x)$  and the PARTIAL DERIVATIVES of  $u(x)$  and  $v(x)$  are CONTINUOUS, then the COMPLEX DERIVATIVE  $df/dz$  exists.

see also ANALYTIC FUNCTION, CAUCHY-RIEMANN EQUATIONS, COMPLEX DERIVATIVE, PSEUDOANALYTIC FUNCTION

**Complex Function**

A FUNCTION whose RANGE is in the COMPLEX NUMBERS is said to be a complex function.

see also REAL FUNCTION, SCALAR FUNCTION, VECTOR FUNCTION

**Complex Matrix**

A MATRIX whose elements may contain COMPLEX NUMBERS. The MATRIX PRODUCT of two  $2 \times 2$  complex matrices is given by

$$\begin{bmatrix} x_{11} + y_{11}i & x_{12} + y_{12}i \\ x_{21} + y_{21}i & x_{22} + y_{22}i \end{bmatrix} \begin{bmatrix} u_{11} + v_{11}i & u_{12} + v_{12}i \\ u_{21} + v_{21}i & u_{22} + v_{22}i \end{bmatrix} \\ = \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} + i \begin{bmatrix} I_{11} & I_{12} \\ I_{21} & I_{22} \end{bmatrix},$$

where

$$\begin{aligned}R_{11} &= u_{11}x_{11} + u_{21}x_{12} - v_{11}y_{11} - v_{21}y_{12} \\ R_{12} &= u_{12}x_{11} + u_{22}x_{12} - v_{12}y_{11} - v_{22}y_{12} \\ R_{21} &= u_{11}x_{21} + u_{21}x_{22} - v_{11}y_{21} - v_{21}y_{22} \\ R_{22} &= u_{12}x_{21} + u_{22}x_{22} - v_{12}y_{21} - v_{22}y_{22} \\ I_{11} &= v_{11}x_{11} + v_{21}x_{12} + u_{11}y_{11} + u_{21}y_{12} \\ I_{12} &= v_{12}x_{11} + v_{22}x_{12} + u_{12}y_{11} + u_{22}y_{12} \\ I_{21} &= v_{11}x_{21} + v_{21}x_{22} + u_{11}y_{21} + u_{21}y_{22} \\ I_{22} &= v_{12}x_{21} + v_{22}x_{22} + u_{12}y_{21} + u_{22}y_{22}.\end{aligned}$$

see also REAL MATRIX

**Complex Multiplication**

TWO COMPLEX NUMBERS  $x = a + ib$  and  $y = c + id$  are multiplied as follows:

$$\begin{aligned}xy &= (a + ib)(c + id) = ac + ibc + iad - bd \\ &= (ac - bd) + i(ad + bc).\end{aligned}$$

However, the multiplication can be carried out using only three REAL multiplications,  $ac$ ,  $bd$ , and  $(a+b)(c+d)$  as

$$\begin{aligned}\Re[(a + ib)(c + id)] &= ac - bd \\ \Im[(a + ib)(c + id)] &= (a + b)(c + d) - ac - bd.\end{aligned}$$

Complex multiplication has a special meaning for ELLIPTIC CURVES.

see also COMPLEX NUMBER, ELLIPTIC CURVE, IMAGINARY PART, MULTIPLICATION, REAL PART

**References**

Cox, D. A. *Primes of the Form  $x^2 + ny^2$ : Fermat, Class Field Theory and Complex Multiplication*. New York: Wiley, 1997.

**Complex Number**

The complex numbers are the FIELD  $\mathbb{C}$  of numbers of the form  $x + iy$ , where  $x$  and  $y$  are REAL NUMBERS and  $i$  is the IMAGINARY NUMBER equal to  $\sqrt{-1}$ . When a single letter  $z = x + iy$  is used to denote a complex number, it is sometimes called an "AFFIX." The FIELD of complex numbers includes the FIELD of REAL NUMBERS as a SUBFIELD.

Through the EULER FORMULA, a complex number

$$z = x + iy \quad (1)$$

may be written in "PHASOR" form

$$z = |z|(\cos \theta + i \sin \theta) = |z|e^{i\theta}. \quad (2)$$

Here,  $|z|$  is known as the MODULUS and  $\theta$  is known as the ARGUMENT or PHASE. The ABSOLUTE SQUARE of

$z$  is defined by  $|z|^2 = zz^*$ , and the argument may be computed from

$$\arg(z) = \theta = \tan^{-1} \left( \frac{y}{x} \right). \quad (3)$$

DE MOIVRE'S IDENTITY relates POWERS of complex numbers

$$z^n = |z|^n [\cos(n\theta) + i \sin(n\theta)]. \quad (4)$$

Finally, the REAL  $\Re(z)$  and IMAGINARY PARTS  $\Im(z)$  are given by

$$\Re(z) = \frac{1}{2}(z + z^*) \quad (5)$$

$$\Im(z) = \frac{z - z^*}{2i} = -\frac{1}{2}i(z - z^*) = \frac{1}{2}i(z^* - z). \quad (6)$$

The POWERS of complex numbers can be written in closed form as follows:

$$z^n = \left[ x^n - \binom{n}{2} x^{n-2} y^2 + \binom{n}{4} x^{n-4} y^4 - \dots \right] + i \left[ \binom{n}{1} x^{n-1} y - \binom{n}{3} x^{n-3} y^3 + \dots \right]. \quad (7)$$

The first few are explicitly

$$z^2 = (x^2 - y^2) + i(2xy) \quad (8)$$

$$z^3 = (x^3 - 3xy^2) + i(3x^2y - y^3) \quad (9)$$

$$z^4 = (x^4 - 6x^2y^2 + y^4) + i(4x^3y - 4xy^3) \quad (10)$$

$$z^5 = (x^5 - 10x^3y^2 + 5xy^4) + i(5x^4y - 10x^2y^3 + y^5) \quad (11)$$

(Abramowitz and Stegun 1972).

### Complex Plane

The plane of COMPLEX NUMBERS spanned by the vectors  $1$  and  $i$ , where  $i$  is the IMAGINARY NUMBER. Every COMPLEX NUMBER corresponds to a unique POINT in the complex plane. The LINE in the plane with  $i = 0$  is the REAL LINE. The complex plane is sometimes called the ARGAND PLANE or GAUSS PLANE, and a plot of COMPLEX NUMBERS in the plane is sometimes called an ARGAND DIAGRAM.

see also AFFINE COMPLEX PLANE, ARGAND DIAGRAM, ARGAND PLANE, BERGMAN SPACE, COMPLEX PROJECTIVE PLANE

#### References

- Courant, R. and Robbins, H. "The Geometric Interpretation of Complex Numbers." §5.2 in *What is Mathematics?: An Elementary Approach to Ideas and Methods*, 2nd ed. Oxford, England: Oxford University Press, pp. 92–97, 1996.

### Complex Projective Plane

The set  $\mathbb{P}^2$  is the set of all EQUIVALENCE CLASSES  $[a, b, c]$  of ordered triples  $(a, b, c) \in \mathbb{C}^3 \setminus (0, 0, 0)$  under the equivalence relation  $(a, b, c) \sim (a', b', c')$  if  $(a, b, c) = (\lambda a', \lambda b', \lambda c')$  for some NONZERO COMPLEX NUMBER  $\lambda$ .

### Complex Representation

see PHASOR

### Complex Structure

The complex structure of a point  $\mathbf{x} = x_1, x_2$  in the PLANE is defined by the linear MAP  $J : \mathbb{R}^2 \rightarrow \mathbb{R}^2$

$$J(x_1, x_2) = (-x_2, x_1),$$

and corresponds to a clockwise rotation by  $\pi/2$ . This map satisfies

$$\begin{aligned} J^2 &= -I \\ (J\mathbf{x}) \cdot (J\mathbf{y}) &= \mathbf{x} \cdot \mathbf{y} \\ (J\mathbf{x}) \cdot \mathbf{x} &= 0, \end{aligned}$$

where  $I$  is the IDENTITY MAP.

More generally, if  $V$  is a 2-D VECTOR SPACE, a linear map  $J : V \rightarrow V$  such that  $J^2 = -I$  is called a complex structure on  $V$ . If  $V = \mathbb{R}^2$ , this collapses to the previous definition.

- Gray, A. *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 3 and 229, 1993.

**Complexity (Number)**

The number of 1s needed to represent an INTEGER using only additions, multiplications, and parentheses are called the integer's complexity. For example,

$$\begin{aligned}
 1 &= 1 \\
 2 &= 1 + 1 \\
 3 &= 1 + 1 + 1 \\
 4 &= (1 + 1)(1 + 1) = 1 + 1 + 1 + 1 \\
 5 &= (1 + 1)(1 + 1) + 1 = 1 + 1 + 1 + 1 + 1 \\
 6 &= (1 + 1)(1 + 1 + 1) \\
 7 &= (1 + 1)(1 + 1 + 1) + 1 \\
 8 &= (1 + 1)(1 + 1)(1 + 1) \\
 9 &= (1 + 1 + 1)(1 + 1 + 1) \\
 10 &= (1 + 1 + 1)(1 + 1 + 1) + 1 \\
 &= (1 + 1)(1 + 1 + 1 + 1 + 1)
 \end{aligned}$$

So, for the first few  $n$ , the complexity is 1, 2, 3, 4, 5, 6, 6, 6, 7, 8, 7, 8, ... (Sloane's A005245).

**Complexity (Sequence)**

see BLOCK GROWTH

**Complexity Theory**

Divides problems into "easy" and "hard" categories. A problem is easy and assigned to the P-PROBLEM (POLYNOMIAL time) class if the number of steps needed to solve it is bounded by some POWER of the problem's size. A problem is hard and assigned to the NP-PROBLEM (nondeterministic POLYNOMIAL time) class if the number of steps is not bounded and may grow exponentially.

However, if a solution is known to an NP-PROBLEM, it can be reduced to a single period verification. A problem is NP-COMPLETE if an ALGORITHM for solving it can be translated into one for solving any other NP-PROBLEM. Examples of NP-COMPLETE PROBLEMS include the HAMILTONIAN CYCLE and TRAVELING SALESMAN PROBLEMS. LINEAR PROGRAMMING, thought to be an NP-PROBLEM, was shown to actually be a P-PROBLEM by L. Khachian in 1979. It is not known if all apparently NP-PROBLEMS are actually P-PROBLEMS.

see also BIT COMPLEXITY, NP-COMPLETE PROBLEM, NP-PROBLEM, P-PROBLEM

**Component**

A GROUP  $L$  is a component of  $H$  if  $L$  is a QUASISIMPLE GROUP which is a SUBNORMAL SUBGROUP of  $H$ .

see also GROUP, QUASISIMPLE GROUP, SUBGROUP, SUBNORMAL

**Composite Knot**

A KNOT which is not a PRIME KNOT. Composite knots are special cases of SATELLITE KNOTS.

see also KNOT, PRIME KNOT, SATELLITE KNOT

**Composite Number**

A POSITIVE INTEGER which is not PRIME (i.e., which has FACTORS other than 1 and itself).

A composite number  $C$  can always be written as a PRODUCT in at least two ways (since  $1 \cdot C$  is always possible). Call these two products

$$C = ab = cd, \quad (1)$$

then it is obviously the case that  $C|ab$  ( $C$  divides  $ab$ ). Set

$$c = mn, \quad (2)$$

where  $m$  is the part of  $C$  which divides  $a$ , and  $n$  the part of  $C$  which divides  $n$ . Then there are  $p$  and  $q$  such that

$$a = mp \quad (3)$$

$$b = nq. \quad (4)$$

Solving  $ab = cd$  for  $d$  gives

$$d = \frac{ab}{c} = \frac{(mp)(nq)}{mn} = pq. \quad (5)$$

It then follows that

$$\begin{aligned} S &\equiv a^2 + b^2 + c^2 + d^2 \\ &= m^2 p^2 + n^2 q^2 + m^2 n^2 + p^2 q^2 \\ &= (m^2 + q^2)(n^2 + p^2). \end{aligned} \quad (6)$$

It therefore follows that  $a^2 + b^2 + c^2 + d^2$  is never PRIME! In fact, the more general result that

$$S \equiv a^k + b^k + c^k + d^k \quad (7)$$

is never PRIME for  $k$  an INTEGER  $\geq 0$  also holds (Honsberger 1991).

There are infinitely many integers of the form  $\lfloor (3/2)^n \rfloor$  and  $\lfloor (4/3)^n \rfloor$  which are composite, where  $\lfloor x \rfloor$  is the FLOOR FUNCTION (Forman and Shapiro, 1967; Guy 1994, p. 220). The first few composite  $\lfloor (3/2)^n \rfloor$  occur for  $n = 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 23, \dots$ , and the few composite  $\lfloor (4/3)^n \rfloor$  occur for  $n = 5, 8, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, \dots$

### Composite Runs

see PRIME GAPS

### Compositeness Certificate

A compositeness certificate is a piece of information which guarantees that a given number  $p$  is COMPOSITE. Possible certificates consist of a FACTOR of a number (which, in general, is much quicker to check by direct division than to determine initially), or of the determination that either

$$a^{p-1} \not\equiv 1 \pmod{p},$$

(i.e.,  $p$  violates FERMAT'S LITTLE THEOREM), or

$$a \not\equiv -1, 1 \text{ and } a^2 \equiv 1 \pmod{p}.$$

A quantity  $a$  satisfying either property is said to be a WITNESS to  $p$ 's compositeness.

see also ADLEMAN-POMERANCE-RUMELY PRIMALITY TEST, FERMAT'S LITTLE THEOREM, MILLER'S PRIMALITY TEST, PRIMALITY CERTIFICATE, WITNESS

### Compositeness Test

A test which always identifies PRIME numbers correctly, but may incorrectly identify a COMPOSITE NUMBER as a PRIME.

see also PRIMALITY TEST

### Composition

The combination of two FUNCTIONS to form a single new OPERATOR. The composition of two functions  $f$  and  $g$  is denoted  $f \circ g$  and is defined by

$$f \circ g = f(g(x))$$

when  $f$  and  $g$  are both functions of  $x$ .

An operation called composition is also defined on BINARY QUADRATIC FORMS. For two numbers represented by two forms, the product can then be represented by the composition. For example, the composition of the forms  $2x^2 + 15y^2$  and  $3x^2 + 10y^2$  is given by  $6x^2 + 5y^2$ , and in this case, the product of 17 and 13 would be represented as  $(6 \cdot 36 + 5 \cdot 1 = 221)$ . There are several algorithms for computing binary quadratic form composition, which is the basis for some factoring methods.

see also ADEM RELATIONS, BINARY OPERATOR, BINARY QUADRATIC FORM

### Composition Series

Every FINITE GROUP  $G$  of order greater than one possesses a finite series of SUBGROUPS, called a composition series, such that

$$I \subset H_s \subset \dots \subset H_2 \subset H_1 \subset G,$$

where  $H_{i+1}$  is a maximal subgroup of  $H_i$ . The QUOTIENT GROUPS  $G/H_1, H_1/H_2, \dots, H_{s-1}/H_s, H_s$  are called composition quotient groups.

see also FINITE GROUP, JORDAN-HÖLDER THEOREM, QUOTIENT GROUP, SUBGROUP

#### References

- Lomont, J. S. *Applications of Finite Groups*. New York: Dover, p. 26, 1993.

### Composition Theorem

Let

$$Q(x, y) \equiv x^2 + y^2.$$

Then

$$Q(x, y)Q(x', y') = Q(xx' - yy', x'y + xy'),$$

since

$$\begin{aligned} (x^2 + y^2)(x'^2 + y'^2) &= (xx' - yy')^2 + (x'y + x'y')^2 \\ &= x^2 x'^2 + y^2 y'^2 + x'^2 y^2 + x^2 y'^2. \end{aligned}$$

see also GENUS THEOREM

### Compound Interest

Let  $P$  be the PRINCIPAL (initial investment),  $r$  be the annual compounded rate,  $i^{(n)}$  the “nominal rate,”  $n$  be the number of times INTEREST is compounded per year (i.e., the year is divided into  $n$  CONVERSION PERIODS), and  $t$  be the number of years (the “term”). The INTEREST rate per CONVERSION PERIOD is then

$$r \equiv \frac{i^{(n)}}{n}. \quad (1)$$

If interest is compounded  $n$  times at an annual rate of  $r$  (where, for example, 10% corresponds to  $r = 0.10$ ), then the effective rate over  $1/n$  the time (what an investor would earn if he did not redeposit his interest after each compounding) is

$$(1 + r)^{1/n}. \quad (2)$$

The total amount of holdings  $A$  after a time  $t$  when interest is re-invested is then

$$A = P \left( 1 + \frac{i^{(n)}}{n} \right)^{nt} = P(1 + r)^{nt}. \quad (3)$$

Note that even if interest is compounded continuously, the return is still finite since

$$\lim_{n \rightarrow \infty} \left( 1 + \frac{1}{n} \right)^n = e, \quad (4)$$

where  $e$  is the base of the NATURAL LOGARITHM.

The time required for a given PRINCIPAL to double (assuming  $n = 1$  CONVERSION PERIOD) is given by solving

$$2P = P(1 + r)^t, \quad (5)$$

or

$$t = \frac{\ln 2}{\ln(1 + r)}, \quad (6)$$

where LN is the NATURAL LOGARITHM. This function can be approximated by the so-called RULE OF 72:

$$t \approx \frac{0.72}{r}. \quad (7)$$

see also  $e$ , INTEREST, LN, NATURAL LOGARITHM, PRINCIPAL, RULE OF 72, SIMPLE INTEREST

### Compound Polyhedron

see POLYHEDRON COMPOUND

### Computability

see COMPLEXITY THEORY

### Computable Function

Any computable function can be incorporated into a PROGRAM using while-loops (i.e., “while something is true, do something else”). For-loops (which have a fixed iteration limit) are a special case of while-loops, so computable functions could also be coded using a combination of for- and while-loops. The ACKERMANN FUNCTION is the simplest example of a well-defined TOTAL FUNCTION which is computable but not PRIMITIVE RECURSIVE, providing a counterexample to the belief in the early 1900s that every computable function was also primitive recursive (Dötzel 1991).

### Computational Complexity

see COMPLEXITY THEORY

### Concatenated Number Sequences

see CONSECUTIVE NUMBER SEQUENCES

### Concatenation

The concatenation of two strings  $a$  and  $b$  is the string  $ab$  formed by joining  $a$  and  $b$ . Thus the concatenation of the strings “book” and “case” is the string “bookcase”. The concatenation of two strings  $a$  and  $b$  is often denoted  $ab$ ,  $a||b$ , or (in *Mathematica*<sup>®</sup>)  $a <> b$ . Concatenation is an associative operation, so that the concatenation of three or more strings, for example  $abc$ ,  $abcd$ , etc., is well-defined.

The concatenation of two or more numbers is the number formed by concatenating their numerals. For example, the concatenation of 1, 234, and 5678 is 12345678. The value of the result depends on the numeric base, which is typically understood from context.

The formula for the concatenation of numbers  $p$  and  $q$  in base  $b$  is

$$p||q = pb^{l(q)} + q,$$

where

$$l(q) = \lfloor \log_b q \rfloor + 1$$

is the LENGTH of  $q$  in base  $b$  and  $\lfloor x \rfloor$  is the FLOOR FUNCTION.

see also CONSECUTIVE NUMBER SEQUENCES, LENGTH (NUMBER), SMARANDACHE SEQUENCES

### Concave

A SET in  $\mathbb{R}^d$  is concave if it *does not* contain all the LINE SEGMENTS connecting any pair of its points. If the SET *does* contain all the LINE SEGMENTS, it is called CONVEX.

see also CONNECTED SET, CONVEX FUNCTION, CONVEX HULL, CONVEX OPTIMIZATION THEORY, CONVEX POLYGON, DELAUNAY TRIANGULATION, SIMPLY CONNECTED

### Concave Function

A function  $f(x)$  is said to be concave on an interval  $[a, b]$  if, for any points  $x_1$  and  $x_2$  in  $[a, b]$ , the function  $-f(x)$  is CONVEX on that interval. If the second DERIVATIVE of  $f$

$$f''(x) > 0,$$

on an open interval  $(a, b)$  (where  $f''(x)$  is the second DERIVATIVE), then  $f$  is concave up on the interval. If

$$f''(x) < 0$$

on the interval, then  $f$  is concave down on it.

### Concentrated

Let  $\mu$  be a POSITIVE MEASURE on a SIGMA ALGEBRA  $M$ , and let  $\lambda$  be an arbitrary (real or complex) MEASURE on  $M$ . If there is a SET  $A \in M$  such that  $\lambda(E) = \lambda(A \cap E)$  for every  $E \in M$ , then  $\lambda$  is said to be concentrated on  $A$ . This is equivalent to requiring that  $\lambda(E) = 0$  whenever  $E \cap A = \emptyset$ .

see also ABSOLUTELY CONTINUOUS, MUTUALLY SINGULAR

#### References

Rudin, W. *Functional Analysis*. New York: McGraw-Hill, p. 121, 1991.

### Concentric

Two geometric figures are said to be concentric if their CENTERS coincide. The region between two concentric CIRCLES is called an ANNULUS.

see also ANNULUS, CONCENTRIC CIRCLES, CONCYCLIC, ECCENTRIC

### Concentric Circles

The region between two CONCENTRIC circles of different RADII is called an ANNULUS.

Given two concentric circles with RADII  $R$  and  $2R$ , what is the probability that a chord chosen at random from the outer circle will cut across the inner circle? Depending on how the "random" CHORD is chosen,  $1/2$ ,  $1/3$ , or  $1/4$  could all be correct answers.

1. Picking any two points on the outer circle and connecting them gives  $1/3$ .
2. Picking any random point on a diagonal and then picking the CHORD that perpendicularly bisects it gives  $1/2$ .
3. Picking any point on the large circle, drawing a line to the center, and then drawing the perpendicularly bisected CHORD gives  $1/4$ .

So some care is obviously needed in specifying what is meant by "random" in this problem.

Given an arbitrary CHORD  $BB'$  to the larger of two concentric CIRCLES centered on  $O$ , the distance between inner and outer intersections is equal on both sides ( $AB = A'B'$ ). To prove this, take the PERPENDICULAR to  $BB'$  passing through  $O$  and crossing at  $P$ . By symmetry, it must be true that  $PA$  and  $PA'$  are equal. Similarly,  $PB$  and  $PB'$  must be equal. Therefore,  $PB - PA = AB$  equals  $PB' - PA' = A'B'$ . Incidentally, this is also true for HOMEOWDS, but the proof is nontrivial.

see also ANNULUS

### Concho-Spiral

The SPACE CURVE with parametric equations

$$\begin{aligned} r &= \mu^u a \\ \theta &= u \\ z &= \mu^u c. \end{aligned}$$

see also CONICAL SPIRAL, SPIRAL

### Conchoid

A curve whose name means "shell form." Let  $C$  be a curve and  $O$  a fixed point. Let  $P$  and  $P'$  be points on a line from  $O$  to  $C$  meeting it at  $Q$ , where  $P'Q = QP = k$ , with  $k$  a given constant. For example, if  $C$  is a CIRCLE and  $O$  is on  $C$ , then the conchoid is a LIMAÇON, while in the special case that  $k$  is the DIAMETER of  $C$ ,

then the conchoid is a CARDIOID. The equation for a parametrically represented curve  $(f(t), g(t))$  with  $O = (x_0, y_0)$  is

$$x = f \pm \frac{k(f - x_0)}{\sqrt{(f - x_0)^2 + (g - y_0)^2}}$$

$$y = g \pm \frac{k(g - y_0)}{\sqrt{(f - x_0)^2 + (g - y_0)^2}}.$$

#### Conchoid of de Sluze

A curve first constructed by René de Sluze in 1662. In CARTESIAN COORDINATES,

$$a(x - a)(x^2 + y^2) = k^2 x^2,$$

and in POLAR COORDINATES,

$$r = \frac{k^2 \cos \theta}{a} + a \sec \theta.$$

The above curve has  $k^2/a = 1$ ,  $a = -0.5$ .

#### Conchoid of Nicomedes

A curve studied by the Greek mathematician Nicomedes in about 200 BC, also called the COCHLOID. It is the LOCUS of points a fixed distance away from a line as measured along a line from the FOCUS point (MacTutor Archive). Nicomedes recognized the three distinct forms

seen in this family. This curve was a favorite with 17th century mathematicians and could be used to solve the problems of CUBE DUPLICATION and ANGLE TRISECTION.

In POLAR COORDINATES,

$$r = b + a \sec \theta. \quad (1)$$

In CARTESIAN COORDINATES,

$$(x - a)^2(x^2 + y^2) = b^2 x^2. \quad (2)$$

The conchoid has  $x = a$  as an asymptote and the AREA between either branch and the ASYMPTOTE is infinite. The AREA of the loop is

$$A = a\sqrt{b^2 - a^2} - 2ab \ln \left( \frac{b + \sqrt{b^2 - a^2}}{a} \right) + b^2 \cos^{-1} \left( \frac{a}{b} \right). \quad (3)$$

see also CONCHOID

#### Concordant Form

A concordant form is an integer TRIPLE  $(a, b, N)$  where

$$\begin{cases} a^2 + b^2 = c^2 \\ a^2 + Nb^2 = d^2, \end{cases}$$

with  $c$  and  $d$  integers. Examples include

$$\begin{cases} 14663^2 + 111384^2 = 112345^2 \\ 14663^2 + 47 \cdot 111384^2 = 763751^2 \\ 1141^2 + 13260^2 = 13309^2 \\ 1141^2 + 53 \cdot 13260^2 = 96541^2 \\ 2873161^2 + 2401080^2 = 3744361^2 \\ 2873161^2 + 83 \cdot 2401080^2 = 22062761^2. \end{cases}$$

Dickson (1962) states that C. H. Brooks and S. Watson found in *The Ladies' and Gentlemen's Diary* (1857) that  $x^2 + y^2$  and  $x^2 + Ny^2$  can be simultaneously squares for  $N < 100$  only for 1, 7, 10, 11, 17, 20, 22, 23, 24, 27, 30, 31, 34, 41, 42, 45, 49, 50, 52, 57, 58, 59, 60, 61, 68, 71, 72, 74, 76, 77, 79, 82, 85, 86, 90, 92, 93, 94, 97,

99, and 100 (which evidently omits 47, 53, and 83 from above). The list of concordant primes less than 1000 is now complete with the possible exception of the 16 primes 103, 131, 191, 223, 271, 311, 431, 439, 443, 593, 607, 641, 743, 821, 929, and 971 (Brown).

### Concur

Two or more lines which intersect in a POINT are said to concur.

see also CONCURRENT

### Concurrent

Two or more LINES are said to be concurrent if they intersect in a single point. Two LINES concur if their TRILINEAR COORDINATES satisfy

$$\begin{vmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{vmatrix} = 0. \quad (1)$$

Three LINES concur if their TRILINEAR COORDINATES satisfy

$$l_1\alpha + m_1\beta + n_1\gamma = 0 \quad (2)$$

$$l_2\alpha + m_2\beta + n_2\gamma = 0 \quad (3)$$

$$l_3\alpha + m_3\beta + n_3\gamma = 0, \quad (4)$$

in which case the point is

$$m_2n_3 - n_2m_3 : n_2l_3 - l_2n_3 : l_2m_3 - m_2l_3. \quad (5)$$

Three lines

$$A_1x + B_1y + C_1 = 0 \quad (6)$$

$$A_2x + B_2y + C_2 = 0 \quad (7)$$

$$A_3x + B_3y + C_3 = 0. \quad (8)$$

are concurrent if their COEFFICIENTS satisfy

$$\begin{vmatrix} A_1 & B_1 & C_1 \\ A_2 & B_2 & C_2 \\ A_3 & B_3 & C_3 \end{vmatrix} = 0. \quad (9)$$

see also CONCYCLIC, POINT

### Concyclic

Four or more points  $P_1, P_2, P_3, P_4, \dots$  which lie on a CIRCLE  $C$  are said to be concyclic. Three points are trivially concyclic since three noncollinear points determine a CIRCLE. The number of the  $n^2$  LATTICE POINTS  $x, y \in [1, n]$  which can be picked with no four concyclic is  $\mathcal{O}(n^{2/3} - \epsilon)$  (Guy 1994).

A theorem states that if any four consecutive points of a POLYGON are not concyclic, then its AREA can be increased by making them concyclic. This fact arises in some PROOFS that the solution to the ISOPERIMETRIC PROBLEM is the CIRCLE.

### Condition

A requirement NECESSARY for a given statement or theorem to hold. Also called a CRITERION.

see also BOUNDARY CONDITIONS, CARMICHAEL CONDITION, CAUCHY BOUNDARY CONDITIONS, CONDITION NUMBER, DIRICHLET BOUNDARY CONDITIONS, DIVERSITY CONDITION, FELLER-LÉVY CONDITION, HÖLDER CONDITION, LICHNEROWICZ CONDITIONS, LINDBERGH CONDITION, LIPSCHITZ CONDITION, LYAPUNOV CONDITION, NEUMANN BOUNDARY CONDITIONS, ROBERTSON CONDITION, ROBIN BOUNDARY CONDITIONS, TAYLOR'S CONDITION, TRIANGLE CONDITION, WEIERSTRASS-ERDMAN CORNER CONDITION, WINKLER CONDITIONS

### Condition Number

The ratio of the largest to smallest SINGULAR VALUE of a system. A system is said to be singular if the condition number is INFINITE, and ill-conditioned if it is too large.

### Conditional Convergence

If the SERIES

$$\sum_{n=0}^{\infty} u_n$$

CONVERGES, but

$$\sum_{n=0}^{\infty} |u_n|$$

does not, where  $|x|$  is the ABSOLUTE VALUE, then the SERIES is said to be conditionally CONVERGENT.

see also ABSOLUTE CONVERGENCE, CONVERGENCE TESTS, RIEMANN SERIES THEOREM, SERIES

### Conditional Probability

The conditional probability of  $A$  given that  $B$  has occurred, denoted  $P(A|B)$ , equals

$$P(A|B) = \frac{P(A \cap B)}{P(B)}, \quad (1)$$

which can be proven directly using a VENN DIAGRAM. Multiplying through, this becomes

$$P(A|B)P(B) = P(A \cap B), \quad (2)$$

which can be generalized to

$$P(A \cup B \cup C) = P(A)P(B|A)P(C|A \cup B). \quad (3)$$

Rearranging (1) gives

$$P(B|A) = \frac{P(B \cap A)}{P(A)}. \quad (4)$$

Solving (4) for  $P(B \cap A) = P(A \cap B)$  and plugging in to (1) gives

$$P(A|B) = \frac{P(A)P(B|A)}{P(B)}. \quad (5)$$

see also BAYES' FORMULA

### Condom Problem

see GLOVE PROBLEM

### Condon-Shortley Phase

The  $(-1)^m$  phase factor in some definitions of the SPHERICAL HARMONICS and associated LEGENDRE POLYNOMIALS. Using the Condon-Shortley convention gives

$$Y_n^m(\theta, \phi) = (-1)^m \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} P_n^m(\cos \theta) e^{im\phi}.$$

see also LEGENDRE POLYNOMIAL, SPHERICAL HARMONIC

### Conductor

see  $j$ -CONDUCTOR

### Cone

A cone is a PYRAMID with a circular CROSS-SECTION. A right cone is a cone with its vertex above the center of its base. A right cone of height  $h$  can be described by the parametric equations

$$x = r(h - z) \cos \theta \quad (1)$$

$$y = r(h - z) \sin \theta \quad (2)$$

$$z = z \quad (3)$$

for  $z \in [0, h]$  and  $\theta \in [0, 2\pi)$ . The VOLUME of a cone is therefore

$$V = \frac{1}{3} A_b h, \quad (4)$$

where  $A_b$  is the base AREA and  $h$  is the height. If the base is circular, then

$$V = \frac{1}{3} \pi r^2 h. \quad (5)$$

This amazing fact was first discovered by Eudoxus, and other proofs were subsequently found by Archimedes in *On the Sphere and Cylinder* (ca. 225 BC) and Euclid in Proposition XII.10 of his *Elements* (Dunham 1990).

The CENTROID can be obtained by setting  $R_2 = 0$  in the equation for the centroid of the CONICAL FRUSTUM,

$$\bar{z} = \frac{\langle z \rangle}{V} = \frac{h(R_1^2 + R_1 R_2 + R_2^2)}{4(R_1^2 + 2R_1 R_2 + 3R_2^2)}, \quad (6)$$

(Beyer 1987, p. 133) yielding

$$\bar{z} = \frac{1}{4} h. \quad (7)$$

For a right circular cone, the SLANT HEIGHT  $s$  is

$$s = \sqrt{r^2 + h^2} \quad (8)$$

and the surface AREA (not including the base) is

$$S = \pi r s = \pi r \sqrt{r^2 + h^2}. \quad (9)$$

In discussions of CONIC SECTIONS, the word cone is often used to refer to two similar cones placed apex to apex. This allows the HYPERBOLA to be defined as the

intersection of a PLANE with both NAPPES (pieces) of the cone.

The LOCUS of the apex of a variable cone containing an ELLIPSE fixed in 3-space is a HYPERBOLA through the FOCI of the ELLIPSE. In addition, the LOCUS of the apex of a cone containing that HYPERBOLA is the original ELLIPSE. Furthermore, the ECCENTRICITIES of the ELLIPSE and HYPERBOLA are reciprocals.

### Cone Graph

A GRAPH  $C_n + \overline{K_m}$ , where  $C_n$  is a CYCLIC GRAPH and  $K_m$  is a COMPLETE GRAPH.

### Cone Net

The mapping of a grid of regularly ruled squares onto a CONE with no overlap or misalignment. Cone nets are possible for vertex angles of  $90^\circ$ ,  $180^\circ$ , and  $270^\circ$ , and are beautifully illustrated by Steinhaus (1983).

#### References

- Steinhaus, H. *Mathematical Snapshots*, 3rd American ed. New York: Oxford University Press, pp. 224–228, 1983.

### Cone (Space)

The JOIN of a TOPOLOGICAL SPACE  $X$  and a point  $P$ ,  $C(X) = X * P$ .

#### References

- Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, p. 6, 1976.

### Cone-Sphere Intersection

Let a CONE of opening parameter  $c$  and vertex at  $(0, 0, 0)$  intersect a SPHERE of RADIUS  $r$  centered at  $(x_0, y_0, z_0)$ , with the CONE oriented such that its axis does not pass through the center of the SPHERE. Then the equations of the curve of intersection are

$$\frac{x^2 + y^2}{c^2} = z^2 \quad (1)$$

$$(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2 = r^2. \quad (2)$$

Combining (1) and (2) gives

$$(x - x_0)^2 + (y - y_0)^2 + \frac{x^2 + y^2}{c^2} - \frac{2z_0}{c} \sqrt{x^2 + y^2} + z_0^2 = r^2 \quad (3)$$

$$x^2 \left(1 + \frac{1}{c^2}\right) - 2x_0x + y^2 \left(1 + \frac{1}{c^2}\right) - 2y_0y + (x_0^2 + y_0^2 + z_0^2 - r^2) - \frac{2z_0}{c} \sqrt{x^2 + y^2} = 0. \quad (4)$$

Therefore,  $x$  and  $y$  are connected by a complicated QUARTIC EQUATION, and  $x$ ,  $y$ , and  $z$  by a QUADRATIC EQUATION.

If the CONE-SPHERE intersection is *on-axis* so that a CONE of opening parameter  $c$  and vertex at  $(0, 0, z_0)$  is oriented with its AXIS along a radial of the SPHERE of radius  $r$  centered at  $(0, 0, 0)$ , then the equations of the curve of intersection are

$$(z - z_0)^2 = \frac{x^2 + y^2}{c^2} \quad (5)$$

$$x^2 + y^2 + z^2 = r^2. \quad (6)$$

Combining (5) and (6) gives

$$c^2(z - z_0)^2 + z^2 = r^2 \quad (7)$$

$$c^2(z^2 - 2z_0z + z_0^2) + z^2 = r^2 \quad (8)$$

$$z^2(c^2 + 1) - 2c^2z_0z + (z_0^2c^2 - r^2) = 0. \quad (9)$$

Using the QUADRATIC EQUATION gives

$$z = \frac{2c^2z_0 \pm \sqrt{4c^4z_0^2 - 4(c^2 + 1)(z_0^2c^2 - r^2)}}{2(c^2 + 1)} \\ = \frac{c^2z_0 \pm \sqrt{c^2(r^2 - z_0^2) + r^2}}{c^2 + 1}. \quad (10)$$

So the curve of intersection is planar. Plugging (10) into (5) shows that the curve is actually a CIRCLE, with RADIUS given by

$$a = \sqrt{r^2 - z^2}. \quad (11)$$

### Confidence Interval

The probability that a measurement will fall within a given CLOSED INTERVAL  $[a, b]$ . For a continuous distribution,

$$CI(a, b) \equiv \int_a^b P(x) dx, \quad (1)$$

where  $P(x)$  is the PROBABILITY DISTRIBUTION FUNCTION. Usually, the confidence interval of interest is symmetrically placed around the mean, so

$$CI(x) \equiv CI(\mu - x, \mu + x) = \int_{\mu-x}^{\mu+x} P(x) dx, \quad (2)$$

where  $\mu$  is the MEAN. For a GAUSSIAN DISTRIBUTION, the probability that a measurement falls within  $n\sigma$  of the mean  $\mu$  is

$$\begin{aligned} \text{CI}(n\sigma) &\equiv \frac{1}{\sigma\sqrt{2\pi}} \int_{\mu-n\sigma}^{\mu+n\sigma} e^{-(x-\mu)^2/2\sigma^2} dx \\ &= \frac{2}{\sigma\sqrt{2\pi}} \int_0^{\mu+n\sigma} e^{-(x-\mu)^2/2\sigma^2} dx. \end{aligned} \quad (3)$$

Now let  $u \equiv (x - \mu)/\sqrt{2}\sigma$ , so  $du = dx/\sqrt{2}\sigma$ . Then

$$\begin{aligned} \text{CI}(n\sigma) &= \frac{2}{\sigma\sqrt{2\pi}} \sqrt{2}\sigma \int_0^{n/\sqrt{2}} e^{-u^2} du \\ &= \frac{2}{\sqrt{\pi}} \int_0^{n/\sqrt{2}} e^{-u^2} du = \text{erf}\left(\frac{n}{\sqrt{2}}\right), \end{aligned} \quad (4)$$

where  $\text{erf}(x)$  is the so-called ERF function. The variate value producing a confidence interval CI is often denoted  $x_{\text{CI}}$ , so

$$x_{\text{CI}} = \sqrt{2} \text{erf}^{-1}(\text{CI}). \quad (5)$$

range	CI
$\sigma$	0.6826895
$2\sigma$	0.9544997
$3\sigma$	0.9973002
$4\sigma$	0.9999366
$5\sigma$	0.9999994

To find the standard deviation range corresponding to a given confidence interval, solve (4) for  $n$ .

$$n = \sqrt{2} \text{erf}^{-1}(\text{CI}) \quad (6)$$

CI	range
0.800	$\pm 1.28155\sigma$
0.900	$\pm 1.64485\sigma$
0.950	$\pm 1.95996\sigma$
0.990	$\pm 2.57583\sigma$

### Configuration

A finite collection of points  $p = (p_1, \dots, p_n)$ ,  $p_i \in \mathbb{R}^d$ , where  $\mathbb{R}^d$  is a EUCLIDEAN SPACE.

see also BAR (EDGE), EUCLIDEAN SPACE, FRAMEWORK, RIGID

### Confluent Hypergeometric Differential Equation

$$xy'' + (b-x)y' - ay = 0, \quad (1)$$

where  $y' \equiv dy/dx$  and with boundary conditions

$${}_1F_1(a; b; 0) = 1 \quad (2)$$

$$\left[ \frac{\partial}{\partial x} {}_1F_1(a; b; x) \right]_{x=0} = \frac{a}{b}. \quad (3)$$

The equation has a REGULAR SINGULAR POINT at 0 and an irregular singularity at  $\infty$ . The solutions are called CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST or SECOND KINDS. Solutions of the first kind are denoted  ${}_1F_1(a; b; x)$  or  $M(a, b, x)$ .

see also HYPERGEOMETRIC DIFFERENTIAL EQUATION, WHITTAKER DIFFERENTIAL EQUATION

### Confluent Hypergeometric Function

see CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND, CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND

### Confluent Hypergeometric Function of the First Kind

The confluent hypergeometric function a degenerate form the HYPERGEOMETRIC FUNCTION  ${}_2F_1(a, b; c; z)$  which arises as a solution the the CONFLUENT HYPERGEOMETRIC DIFFERENTIAL EQUATION. It is commonly denoted  ${}_1F_1(a; b; z)$ ,  $M(a, b, z)$ , or  $\Phi(a; b; z)$ , and is also known as KUMMER'S FUNCTION of the first kind. An alternate form of the solution to the Confluent Hypergeometric Differential Equation is known as the WHITTAKER FUNCTION.

The confluent hypergeometric function has a HYPERGEOMETRIC SERIES given by

$${}_1F_1(a; b; z) = 1 + \frac{a}{b}z + \frac{a(a+1)}{b(b+1)} \frac{z^2}{2!} + \dots = \sum_{k=0}^{\infty} \frac{(a)_k}{(b)_k} \frac{z^k}{k!}, \quad (1)$$

where  $(a)_k$  and  $(b)_k$  are POCHHAMMER SYMBOLS. If  $a$  and  $b$  are INTEGERS,  $a < 0$ , and either  $b > 0$  or  $b < a$ , then the series yields a POLYNOMIAL with a finite number of terms. If  $b$  is an INTEGER  $\leq 0$ , then  ${}_1F_1(a; b; z)$  is undefined. The confluent hypergeometric function also has an integral representation

$${}_1F_1(a; b; z) = \frac{\Gamma(b)}{\Gamma(b-a)\Gamma(a)} \int_0^1 e^{zt} t^{a-1} (1-t)^{b-a-1} dt \quad (2)$$

(Abramowitz and Stegun 1972, p. 505).

BESSEL FUNCTIONS, the ERROR FUNCTION, the incomplete GAMMA FUNCTION, HERMITE POLYNOMIAL, LAGUERRE POLYNOMIAL, as well as other are all special

cases of this function (Abramowitz and Stegun 1972, p. 509).

KUMMER'S SECOND FORMULA gives

$${}_1F_1\left(\frac{1}{2} + m; 2m + 1; z\right) = M_{0,m}(z) = z^{m+1/2} \times \left[ 1 + \sum_{p=1}^{\infty} \frac{z^{2p}}{2^{4p} p! (m+1)(m+2) \cdots (m+p)} \right], \quad (3)$$

where  ${}_1F_1$  is the CONFLUENT HYPERGEOMETRIC FUNCTION and  $m \neq -1/2, -1, -3/2, \dots$

### Confluent Hypergeometric Function of the Second Kind

Gives the second linearly independent solution to the CONFLUENT HYPERGEOMETRIC DIFFERENTIAL EQUATION. It is also known as the KUMMER'S FUNCTION of the second kind, the TRICOMI FUNCTION, or the GORDON FUNCTION. It is denoted  $U(a, b, z)$  and has an integral representation

$$U(a, b, z) = \frac{1}{\Gamma(a)} \int_0^\infty e^{-zt} t^{a-1} (1+t)^{b-a-1} dt$$

(Abramowitz and Stegun 1972, p. 505). The WHITTAKER FUNCTIONS give an alternative form of the solution. For small  $z$ , the function behaves as  $z^{1-b}$ .

### Confluent Hypergeometric Limit Function

$${}_0F_1(; a; z) \equiv \lim_{q \rightarrow \infty} {}_1F_1\left(q; a; \frac{z}{q}\right). \quad (1)$$

It has a series expansion

$${}_0F_1(; a; z) = \sum_{n=0}^{\infty} \frac{z^n}{(a)_n n!} \quad (2)$$

and satisfies

$$z \frac{d^2 y}{dz^2} + a \frac{dy}{dz} - y = 0. \quad (3)$$

A BESSEL FUNCTION OF THE FIRST KIND can be expressed in terms of this function by

$$J_n(x) = \frac{(\frac{1}{2}x)^n}{n!} {}_0F_1(; n+1; -\frac{1}{4}x^2) \quad (4)$$

(Petkovšek *et al.* 1996).

### Confocal Ellipsoidal Coordinates

The confocal ellipsoidal coordinates (called simply ellipsoidal coordinates by Morse and Feshbach 1953) are given by the equations

$$\frac{x^2}{a^2 + \xi} + \frac{y^2}{b^2 + \xi} + \frac{z^2}{c^2 + \xi} = 1 \quad (1)$$

$$\frac{x^2}{a^2 + \eta} + \frac{y^2}{b^2 + \eta} + \frac{z^2}{c^2 + \eta} = 1 \quad (2)$$

$$\frac{x^2}{a^2 + \zeta} + \frac{y^2}{b^2 + \zeta} + \frac{z^2}{c^2 + \zeta} = 1, \quad (3)$$

where  $-c^2 < \xi < \infty$ ,  $-b^2 < \eta < -c^2$ , and  $-a^2 < \zeta < -b^2$ . Surfaces of constant  $\xi$  are confocal ELLIPSOIDS, surfaces of constant  $\eta$  are one-sheeted HYPERBOLOIDS, and surfaces of constant  $\zeta$  are two-sheeted HYPERBOLOIDS. For every  $(x, y, z)$ , there is a unique set of ellipsoidal coordinates. However,  $(\xi, \eta, \zeta)$  specifies eight points symmetrically located in octants. Solving for  $x$ ,  $y$ , and  $z$  gives

$$x^2 = \frac{(a^2 + \xi)(a^2 + \eta)(a^2 + \zeta)}{(b^2 - a^2)(c^2 - a^2)} \quad (4)$$

$$y^2 = \frac{(b^2 + \xi)(b^2 + \eta)(b^2 + \zeta)}{(a^2 - b^2)(c^2 - b^2)} \quad (5)$$

$$z^2 = \frac{(c^2 + \xi)(c^2 + \eta)(c^2 + \zeta)}{(a^2 - c^2)(b^2 - c^2)}. \quad (6)$$

The LAPLACIAN is

$$\begin{aligned} \nabla^2 \Psi = & (\eta - \zeta) f(\xi) \frac{\partial}{\partial \xi} \left[ f(\xi) \frac{\partial \Psi}{\partial \xi} \right] \\ & + (\zeta - \xi) f(\eta) \frac{\partial}{\partial \eta} \left[ f(\eta) \frac{\partial \Psi}{\partial \eta} \right] + (\xi - \eta) f(\zeta) \frac{\partial}{\partial \zeta} \left[ f(\zeta) \frac{\partial \Psi}{\partial \zeta} \right], \end{aligned} \quad (7)$$

where

$$f(x) \equiv \sqrt{(x + a^2)(x + b^2)(x + c^2)}. \quad (8)$$

Another definition is

$$\frac{x^2}{a^2 - \lambda} + \frac{y^2}{b^2 - \lambda} + \frac{z^2}{c^2 - \lambda} = 1 \quad (9)$$

$$\frac{x^2}{a^2 - \mu} + \frac{y^2}{b^2 - \mu} + \frac{z^2}{c^2 - \mu} = 1 \quad (10)$$

$$\frac{x^2}{a^2 - \nu} + \frac{y^2}{b^2 - \nu} + \frac{z^2}{c^2 - \nu} = 1, \quad (11)$$

where

$$\lambda < c^2 < \mu < b^2 < \nu < a^2 \quad (12)$$

(Arfken 1970, pp. 117–118). Byerly (1959, p. 251) uses a slightly different definition in which the Greek variables are replaced by their squares, and  $a = 0$ . Equation (9) represents an ELLIPSOID, (10) represents a one-sheeted

HYPERBOLOID, and (11) represents a two-sheeted HYPERBOLOID. In terms of CARTESIAN COORDINATES,

$$x^2 = \frac{(a^2 - \lambda)(a^2 - \mu)(a^2 - \nu)}{(a^2 - b^2)(a^2 - c^2)} \quad (13)$$

$$y^2 = \frac{(b^2 - \lambda)(b^2 - \mu)(b^2 - \nu)}{(b^2 - a^2)(b^2 - c^2)} \quad (14)$$

$$z^2 = \frac{(c^2 - \lambda)(c^2 - \mu)(c^2 - \nu)}{(c^2 - a^2)(c^2 - b^2)}. \quad (15)$$

The SCALE FACTORS are

$$h_\lambda = \sqrt{\frac{(\mu - \lambda)(\nu - \lambda)}{4(a^2 - \lambda)(b^2 - \lambda)(c^2 - \lambda)}} \quad (16)$$

$$h_\mu = \sqrt{\frac{(\nu - \mu)(\lambda - \mu)}{4(a^2 - \mu)(b^2 - \mu)(c^2 - \mu)}} \quad (17)$$

$$h_\nu = \sqrt{\frac{(\lambda - \nu)(\mu - \nu)}{4(a^2 - \nu)(b^2 - \nu)(c^2 - \nu)}}. \quad (18)$$

The LAPLACIAN is

$$\begin{aligned} \nabla^2 = & 2 \frac{a^2 b^2 + a^2 c^2 + b^2 c^2 - 2\nu(a^2 + b^2 + c^2) + 3\nu^2}{(\mu - \nu)(\nu - \lambda)} \frac{\partial}{\partial \nu} \\ & + \frac{4(a^2 - \nu)(b^2 - \nu)(c^2 - \nu)}{(\mu - \nu)(\nu - \lambda)} \frac{\partial^2}{\partial \nu^2} \\ & + 2 \frac{a^2 b^2 + a^2 c^2 + b^2 c^2 - 2\mu(a^2 + b^2 + c^2) + 3\mu^2}{(\nu - \mu)(\mu - \lambda)} \frac{\partial}{\partial \mu} \\ & + \frac{4(a^2 - \mu)(b^2 - \mu)(c^2 - \mu)}{(\mu - \lambda)(\nu - \mu)} \frac{\partial^2}{\partial \mu^2} \\ & + 2 \frac{-(a^2 b^2 + a^2 c^2 + b^2 c^2) + 2\lambda(a^2 + b^2 + c^2) - 3\lambda^2}{(\mu - \lambda)(\nu - \lambda)} \frac{\partial}{\partial \lambda} \\ & + \frac{4(a^2 - \lambda)(b^2 - \lambda)(c^2 - \lambda)}{(\mu - \lambda)(\nu - \lambda)} \frac{\partial^2}{\partial \lambda^2}. \end{aligned} \quad (19)$$

Using the NOTATION of Byerly (1959, pp. 252–253), this can be reduced to

$$\nabla^2 = (\mu^2 - \nu^2) \frac{\partial^2}{\partial \alpha^2} + (\lambda^2 - \nu^2) \frac{\partial^2}{\partial \beta^2} + (\lambda^2 - \mu^2) \frac{\partial^2}{\partial \gamma^2}, \quad (20)$$

where

$$\begin{aligned} \alpha &= c \int_c^\lambda \frac{d\lambda}{\sqrt{(\lambda^2 - b^2)(\lambda^2 - c^2)}} \\ &= F\left(\frac{b}{c}, \frac{\pi}{2}\right) - F\left(\frac{b}{c}, \sin^{-1}\left(\frac{c}{\lambda}\right)\right) \end{aligned} \quad (21)$$

$$\begin{aligned} \beta &= c \int_b^\mu \frac{d\mu}{\sqrt{(c^2 - \mu^2)(\mu^2 - b^2)}} \\ &= F\left[\sqrt{1 - \frac{b^2}{c^2}}, \sin^{-1}\left(\sqrt{\frac{1 - \frac{b^2}{\mu^2}}{1 - \frac{b^2}{c^2}}}\right)\right] \end{aligned} \quad (22)$$

$$\begin{aligned} \gamma &= c \int_0^\nu \frac{d\nu}{\sqrt{(b^2 - \nu^2)(c^2 - \nu^2)}} \\ &= F\left(\frac{b}{c}, \sin^{-1}\left(\frac{\nu}{b}\right)\right). \end{aligned} \quad (23)$$

Here,  $F$  is an ELLIPTIC INTEGRAL OF THE FIRST KIND. In terms of  $\alpha$ ,  $\beta$ , and  $\gamma$ ,

$$\lambda = c \operatorname{dc} \left( \alpha, \frac{b}{c} \right) \quad (24)$$

$$\mu = b \operatorname{nd} \left( \beta, \sqrt{1 - \frac{b^2}{c^2}} \right) \quad (25)$$

$$\nu = b \operatorname{sn} \left( \gamma, \frac{b}{c} \right), \quad (26)$$

where  $\operatorname{dc}$ ,  $\operatorname{nd}$  and  $\operatorname{sn}$  are JACOBI ELLIPTIC FUNCTIONS. The HELMHOLTZ DIFFERENTIAL EQUATION is separable in confocal ellipsoidal coordinates.

#### Conformal Latitude

An AUXILIARY LATITUDE defined by

$$\begin{aligned} \chi & \equiv 2 \tan^{-1} \left\{ \tan\left(\frac{1}{4}\pi + \frac{1}{2}\phi\right) \left[ \frac{1 - e \sin \phi}{1 + e \sin \phi} \right]^{e/2} \right\} - \frac{1}{2}\pi \\ & = 2 \tan^{-1} \left[ \frac{1 + \sin \phi}{1 - \sin \phi} \left( \frac{1 - e \sin \phi}{1 + e \sin \phi} \right)^e \right]^{1/2} - \frac{1}{2}\pi \\ & = \phi - \left(\frac{1}{2}e^2 + \frac{5}{24}e^4 + \frac{3}{32}e^6 + \frac{281}{5760}e^8 + \dots\right) \sin(2\phi) \\ & \quad + \left(\frac{5}{48}e^4 + \frac{7}{80}e^6 + \frac{697}{11520}e^8 + \dots\right) \sin(4\phi) \\ & \quad - \left(\frac{13}{480}e^6 + \frac{461}{13440} + \dots\right) \sin(6\phi) \\ & \quad + \left(\frac{1237}{161280}e^8 + \dots\right) \sin(8\phi) + \dots \end{aligned}$$

The inverse is obtained by iterating the equation

$$\phi = 2 \tan^{-1} \left[ \tan\left(\frac{1}{4}\pi + \frac{1}{2}\chi\right) \left( \frac{1 + e \sin \phi}{1 - e \sin \phi} \right)^{e/2} \right] - \frac{1}{2}\pi$$

using  $\phi = \chi$  as the first trial. A series form is

$$\begin{aligned} \phi = \chi & + \left(\frac{1}{2}e^2 + \frac{5}{24}e^4 + \frac{1}{12}e^6 + \frac{13}{360}e^8 + \dots\right) \sin(2\chi) \\ & + \left(\frac{7}{48}e^4 + \frac{29}{240}e^6 + \frac{811}{11520}e^8 + \dots\right) \sin(4\chi) \\ & + \left(\frac{7}{120}e^6 + \frac{81}{1120}e^8 + \dots\right) \sin(6\chi) \\ & + \left(\frac{4279}{161280}e^8 + \dots\right) \sin(8\chi) + \dots \end{aligned}$$

The conformal latitude was called the ISOMETRIC LATITUDE by Adams (1921), but this term is now used to refer to a different quantity.

### Conformal Map

A TRANSFORMATION which preserves ANGLES is known as conformal. For a transformation to be conformal, it must be an ANALYTIC FUNCTION and have a NONZERO DERIVATIVE. Let  $\theta$  and  $\phi$  be the tangents to the curves  $\gamma$  and  $f(\gamma)$  at  $z_0$  and  $w_0$ ,

$$w - w_0 \equiv f(z) - f(z_0) = \frac{f(z) - f(z_0)}{z - z_0}(z - z_0) \quad (1)$$

$$\arg(w - w_0) = \arg \left[ \frac{f(z) - f(z_0)}{z - z_0} \right] + \arg(z - z_0). \quad (2)$$

Then as  $w \rightarrow w_0$  and  $z \rightarrow z_0$ ,

$$\phi = \arg f'(z_0) + \theta \quad (3)$$

$$|w| = |f'(z_0)| |z|. \quad (4)$$

### Conformal Solution

By letting  $w \equiv f(z)$ , the REAL and IMAGINARY PARTS of  $w$  must satisfy the CAUCHY-RIEMANN EQUATIONS and LAPLACE'S EQUATION, so they automatically provide a scalar POTENTIAL and a so-called stream function. If a physical problem can be found for which the solution is valid, we obtain a solution—which may have been very difficult to obtain directly—by working backwards. Let

$$Az^n = Ar^n e^{in\theta}, \quad (1)$$

the REAL and IMAGINARY PARTS then give

$$\phi = Ar^n \cos(n\theta) \quad (2)$$

$$\psi = Ar^n \sin(n\theta). \quad (3)$$

For  $n = -2$ ,

$$\phi = \frac{A}{r^2} \cos(2\theta) \quad (4)$$

$$\psi = -\frac{A}{r^2} \sin(2\theta), \quad (5)$$

which is a double system of LEMNISCATES (Lamb 1945, p. 69). For  $n = -1$ ,

$$\phi = \frac{A}{r} \cos \theta \quad (6)$$

$$\psi = -\frac{A}{r} \sin \theta. \quad (7)$$

This solution consists of two systems of CIRCLES, and  $\phi$  is the POTENTIAL FUNCTION for two PARALLEL opposite charged line charges (Feynman *et al.* 1989, §7-5; Lamb 1945, p. 69). For  $n = 1/2$ ,

$$\phi = Ar^{1/2} \cos\left(\frac{\theta}{2}\right) = A\sqrt{\frac{\sqrt{x^2 + y^2} + x}{2}} \quad (8)$$

$$\psi = Ar^{1/2} \sin\left(\frac{\theta}{2}\right) = A\sqrt{\frac{\sqrt{x^2 + y^2} - x}{2}}. \quad (9)$$

$\phi$  gives the field near the edge of a thin plate (Feynman *et al.* 1989, §7-5). For  $n = 1$ ,

$$\phi = Ar \cos \theta = Ax \quad (10)$$

$$\psi = Ar \sin \theta = Ay. \quad (11)$$

This is two straight lines (Lamb 1945, p. 68). For  $n = 3/2$ ,

$$w = Ar^{3/2} e^{3i\theta/2}. \quad (12)$$

$\phi$  gives the field near the outside of a rectangular corner (Feynman *et al.* 1989, §7-5). For  $n = 2$ ,

$$w = A(x + iy)^2 = A[(x^2 - y^2) + 2ixy] \quad (13)$$

$$\phi = A(x^2 - y^2) = Ar^2 \cos(2\theta) \quad (14)$$

$$\psi = 2Axy = Ar^2 \sin(2\theta). \quad (15)$$

These are two PERPENDICULAR HYPERBOLAS, and  $\phi$  is the POTENTIAL FUNCTION near the middle of two point charges or the field on the opening side of a charged RIGHT ANGLE conductor (Feynman 1989, §7-3).

see CONFORMAL MAP

**Congruence**

If  $b - c$  is integrally divisible by  $a$ , then  $b$  and  $c$  are said to be congruent with MODULUS  $a$ . This is written mathematically as  $b \equiv c \pmod{a}$ . If  $b - c$  is *not* divisible by  $a$ , then we say  $b \not\equiv c \pmod{a}$ . The  $\pmod{a}$  is sometimes omitted when the MODULUS  $a$  is understood for a given computation, so care must be taken not to confuse the symbol  $\equiv$  with that for an EQUIVALENCE. The quantity  $b$  is called the RESIDUE or REMAINDER. The COMMON RESIDUE is taken to be NONNEGATIVE and smaller than  $m$ , and the MINIMAL RESIDUE is  $b$  or  $b - m$ , whichever is smaller in ABSOLUTE VALUE. In many computer languages (such as FORTRAN or *Mathematica*<sup>®</sup>), the COMMON RESIDUE of  $c \pmod{a}$  is written  $\text{mod}(c, a)$ .

Congruence arithmetic is perhaps most familiar as a generalization of the arithmetic of the clock: 40 minutes past the hour plus 35 minutes gives  $40 + 35 \equiv 15 \pmod{60}$ , or 15 minutes past the hour, and 10 o'clock a.m. plus five hours gives  $10 + 5 \equiv 3 \pmod{12}$ , or 3 o'clock p.m. Congruences satisfy a number of important properties, and are extremely useful in many areas of NUMBER THEORY. Using congruences, simple DIVISIBILITY TESTS to check whether a given number is divisible by another number can sometimes be derived. For example, if the sum of a number's digits is divisible by 3 (9), then the original number is divisible by 3 (9).

Congruences also have their limitations. For example, if  $a \equiv b$  and  $c \equiv d \pmod{n}$ , then it follows that  $a^x \equiv b^x$ , but usually not that  $x^c \equiv x^d$  or  $a^c \equiv b^d$ . In addition, by "rolling over," congruences discard absolute information. For example, knowing the number of minutes past the hour is useful, but knowing the hour the minutes are past is often more useful still.

Let  $a \equiv a' \pmod{m}$  and  $b \equiv b' \pmod{m}$ , then important properties of congruences include the following, where  $\Rightarrow$  means "IMPLIES":

1. Equivalence:  $a \equiv b \pmod{0} \Rightarrow a = b$ .
2. Determination: either  $a \equiv b \pmod{m}$  or  $a \not\equiv b \pmod{m}$ .
3. Reflexivity:  $a \equiv a \pmod{m}$ .
4. Symmetry:  $a \equiv b \pmod{m} \Rightarrow b \equiv a \pmod{m}$ .
5. Transitivity:  $a \equiv b \pmod{m}$  and  $b \equiv c \pmod{m} \Rightarrow a \equiv c \pmod{m}$ .
6.  $a + b \equiv a' + b' \pmod{m}$ .
7.  $a - b \equiv a' - b' \pmod{m}$ .
8.  $ab \equiv a'b' \pmod{m}$ .
9.  $a \equiv b \pmod{m} \Rightarrow ka \equiv kb \pmod{m}$ .
10.  $a \equiv b \pmod{m} \Rightarrow a^n \equiv b^n \pmod{m}$ .
11.  $a \equiv b \pmod{m_1}$  and  $a \equiv b \pmod{m_2} \Rightarrow a \equiv b \pmod{[m_1, m_2]}$ , where  $[m_1, m_2]$  is the LEAST COMMON MULTIPLE.
12.  $ak \equiv bk \pmod{m} \Rightarrow a \equiv b \pmod{\frac{m}{(k, m)}}$ , where  $(k, m)$  is the GREATEST COMMON DIVISOR.

13. If  $a \equiv b \pmod{m}$ , then  $P(a) \equiv P(b) \pmod{m}$ , for  $P(x)$  a POLYNOMIAL.

Properties (6–8) can be proved simply by defining

$$a \equiv a' + rd \quad (1)$$

$$b \equiv b' + sd, \quad (2)$$

where  $r$  and  $s$  are INTEGERS. Then

$$a + b \equiv a' + b' + (r + s)d \quad (3)$$

$$a - b \equiv a' - b' + (r - s)d \quad (4)$$

$$ab \equiv a'b' + (a's + b'r + rsd)d, \quad (5)$$

so the properties are true.

Congruences also apply to FRACTIONS. For example, note that  $\pmod{7}$

$$2 \times 4 \equiv 1 \quad 3 \times 3 \equiv 2 \quad 6 \times 6 \equiv 1 \pmod{7}, \quad (6)$$

so

$$\frac{1}{2} \equiv 4 \quad \frac{1}{4} \equiv 2 \quad \frac{2}{3} \equiv 3 \quad \frac{1}{6} \equiv 6 \pmod{7}. \quad (7)$$

To find  $p/q \pmod{m}$ , use an ALGORITHM similar to the GREEDY ALGORITHM. Let  $q_0 \equiv q$  and find

$$p_0 = \left\lceil \frac{m}{q_0} \right\rceil, \quad (8)$$

where  $\lceil x \rceil$  is the CEILING FUNCTION, then compute

$$q_1 \equiv q_0 p_0 \pmod{m}. \quad (9)$$

Iterate until  $q_n = 1$ , then

$$\frac{p}{q} \equiv p \prod_{i=0}^{n-1} p_i \pmod{m}. \quad (10)$$

This method always works for  $m$  PRIME, and sometimes even for  $m$  COMPOSITE. However, for a COMPOSITE  $m$ , the method can fail by reaching 0 (Conway and Guy 1996).

**A LINEAR CONGRUENCE**

$$ax \equiv b \pmod{m} \quad (11)$$

is solvable IFF the congruence

$$b \equiv 0 \pmod{(a, m)} \quad (12)$$

is solvable, where  $d \equiv (a, m)$  is the GREATEST COMMON DIVISOR, in which case the solutions are  $x_0, x_0 + m/d, x_0 + 2m/d, \dots, x_0 + (d - 1)m/d$ , where  $x_0 < m/d$ . If  $d = 1$ , then there is only one solution.

A general QUADRATIC CONGRUENCE

$$a_2x^2 + a_1x + a_0 \equiv 0 \pmod{n} \quad (13)$$

can be reduced to the congruence

$$x^2 \equiv q \pmod{p} \quad (14)$$

and can be solved using EXCLUDENTS. Solution of the general polynomial congruence

$$a_mx^m + \dots + a_2x^2 + a_1x + a_0 \equiv 0 \pmod{n} \quad (15)$$

is intractable. Any polynomial congruence will give congruent results when congruent values are substituted.

Two simultaneous congruences

$$x \equiv a \pmod{m} \quad (16)$$

$$x \equiv b \pmod{n} \quad (17)$$

are solvable only when  $x \equiv b \pmod{(m,n)}$ , and the single solution is

$$x \equiv x_0 \pmod{[m,n]}, \quad (18)$$

where  $x_0 < m/d$ .

### Congruum

A number  $h$  which satisfies the conditions of the CONGRUUM PROBLEM:

$$x^2 + h = a^2$$

and

$$x^2 - h = b^2.$$

see also CONCORDANT FORM, CONGRUUM PROBLEM

### Congruum Problem

Find a SQUARE NUMBER  $x^2$  such that, when a given number  $h$  is added or subtracted, new SQUARE NUMBERS are obtained so that

$$x^2 + h = a^2 \quad (1)$$

and

$$x^2 - h = b^2. \quad (2)$$

This problem was posed by the mathematicians Théodore and Jean de Palerma in a mathematical tournament organized by Frederick II in Pisa in 1225. The solution (Ore 1988, pp. 188–191) is

$$x = m^2 + n^2 \quad (3)$$

$$h = 4mn(m^2 - n^2), \quad (4)$$

where  $m$  and  $n$  are INTEGERS. Fibonacci proved that all numbers  $h$  (the CONGRUA) are divisible by 24. FERMAT'S RIGHT TRIANGLE THEOREM is equivalent to the result that a congruum cannot be a SQUARE NUMBER. A table for small  $m$  and  $n$  is given in Ore (1988, p. 191), and a larger one (for  $h \leq 1000$ ) by Lagrange (1977).

$m$	$n$	$h$	$x$
2	1	24	5
3	1	96	10
3	2	120	13
4	1	240	17
4	3	336	25

## Conic Section

The conic sections are the nondegenerate curves generated by the intersections of a PLANE with one or two NAPPES of a CONE. For a PLANE parallel to a CROSS-SECTION, a CIRCLE is produced. The closed curve produced by the intersection of a single NAPPE with an inclined PLANE is an ELLIPSE or PARABOLA. The curve produced by a PLANE intersecting both NAPPES is a HYPERBOLA. The ELLIPSE and HYPERBOLA are known as CENTRAL CONICS.

Because of this simple geometric interpretation, the conic sections were studied by the Greeks long before their application to inverse square law orbits was known. Apollonius wrote the classic ancient work on the subject entitled *On Conics*. Kepler was the first to notice that planetary orbits were ELLIPSES, and Newton was then able to derive the shape of orbits mathematically using CALCULUS, under the assumption that gravitational force goes as the inverse square of distance. Depending on the energy of the orbiting body, orbit shapes which are any of the four types of conic sections are possible.

A conic section may more formally be defined as the locus of a point  $P$  that moves in the PLANE of a fixed point  $F$  called the FOCUS and a fixed line  $d$  called the

DIRECTRIX (with  $F$  not on  $d$ ) such that the ratio of the distance of  $P$  from  $F$  to its distance from  $d$  is a constant  $e$  called the ECCENTRICITY. For a FOCUS  $(0,0)$  and DIRECTRIX  $x = -a$ , the equation is

$$x^2 + y^2 = e^2(x + a)^2.$$

If  $e = 1$ , the conic is a PARABOLA, if  $e < 1$ , the conic is an ELLIPSE, and if  $e > 1$ , it is a HYPERBOLA.

In standard form, a conic section is written

$$y^2 = 2Rx - (1 - e^2)x^2,$$

where  $R$  is the RADIUS OF CURVATURE and  $e$  is the ECCENTRICITY. Five points in a plane determine a conic (Le Lionnais 1983, p. 56).

## Conic Section Tangent

Given a CONIC SECTION

$$x^2 + y^2 + 2gx + 2fy + c = 0,$$

the tangent at  $(x_1, y_1)$  is given by the equation

$$xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c = 0.$$

## Conical Coordinates

Arfken (1970) and Morse and Feshbach (1953) use slightly different definitions of these coordinates. The system used in *Mathematica*<sup>®</sup> (Wolfram Research, Inc., Champaign, Illinois) is

$$x = \frac{\lambda\mu\nu}{ab} \quad (1)$$

$$y = \frac{\lambda}{a} \sqrt{\frac{(\mu^2 - a^2)(\nu^2 - a^2)}{a^2 - b^2}} \quad (2)$$

$$z = \frac{\lambda}{b} \sqrt{\frac{(\mu^2 - b^2)(\nu^2 - b^2)}{b^2 - a^2}}, \quad (3)$$

where  $b^2 > \mu^2 > c^2 > \nu^2$ . The NOTATION of Byerly replaces  $\lambda$  with  $r$ , and  $a$  and  $b$  with  $b$  and  $c$ . The above equations give

$$x^2 + y^2 + z^2 = \lambda^2 \quad (4)$$

$$\frac{x^2}{\mu^2} + \frac{y^2}{\mu^2 - a^2} + \frac{z^2}{\mu^2 - b^2} = 0 \quad (5)$$

$$\frac{x^2}{\nu^2} + \frac{y^2}{\nu^2 - a^2} + \frac{z^2}{\nu^2 - b^2} = 0. \quad (6)$$

The SCALE FACTORS are

$$h_\lambda = 1 \quad (7)$$

$$h_\mu = \sqrt{\frac{\lambda^2(\mu^2 - \nu^2)}{(\mu^2 - a^2)(b^2 - \mu^2)}} \quad (8)$$

$$h_\nu = \sqrt{\frac{\lambda^2(\mu^2 - \nu^2)}{(\nu^2 - a^2)(\nu^2 - b^2)}}. \quad (9)$$

The LAPLACIAN is

$$\begin{aligned} \nabla^2 = & \frac{\nu(2\nu^2 - a^2 - b^2)}{(\mu - \nu)(\mu + \nu)\lambda^2} \frac{\partial}{\partial \nu} \\ & + \frac{(a - \nu)(a + \nu)(\nu - b)(\nu + b)}{(\nu - \mu)(\nu + \mu)\lambda^2} \frac{\partial^2}{\partial \nu^2} \\ & + \frac{\mu(2\mu^2 - a^2 - b^2)}{(\nu - \mu)(\nu + \mu)\lambda^2} \frac{\partial}{\partial \mu} \\ & + \frac{(\mu - b)(\mu + b)(\mu - a)(\mu + a)}{(\nu - \mu)(\nu + \mu)\lambda^2} \frac{\partial^2}{\partial \mu^2} \\ & + \frac{2}{\lambda} \frac{\partial}{\partial \lambda} + \frac{\partial^2}{\partial \lambda^2}. \end{aligned} \quad (10)$$

The HELMHOLTZ DIFFERENTIAL EQUATION is separable in conical coordinates.

see also HELMHOLTZ DIFFERENTIAL EQUATION—CONICAL COORDINATES

## Conical Frustum

A conical frustum is a FRUSTUM created by slicing the top off a CONE (with the cut made parallel to the base). For a right circular CONE, let  $s$  be the slant height and  $R_1$  and  $R_2$  the top and bottom RADII. Then

$$s = \sqrt{(R_1 - R_2)^2 + h^2}. \quad (1)$$

The SURFACE AREA, not including the top and bottom CIRCLES, is

$$A = \pi(R_1 + R_2)s = \pi(R_1 + R_2)\sqrt{(R_1 - R_2)^2 + h^2}. \quad (2)$$

The VOLUME of the frustum is given by

$$V = \pi \int_0^h [r(z)]^2 dz. \quad (3)$$

But

$$r(z) = R_1 + (R_2 - R_1)\frac{z}{h}, \quad (4)$$

so

$$\begin{aligned} V &= \pi \int_0^h \left[ R_1 + (R_2 - R_1)\frac{z}{h} \right]^2 dz \\ &= \frac{1}{3}\pi h(R_1^2 + R_1R_2 + R_2^2). \end{aligned} \quad (5)$$

This formula can be generalized to any PYRAMID by letting  $A_1$  be the base AREAS of the top and bottom of the frustum. Then the VOLUME can be written as

$$V = \frac{1}{3}h(A_1 + A_2 + \sqrt{A_1A_2}). \quad (6)$$

The weighted mean of  $z$  over the frustum is

$$\langle z \rangle = \pi \int_0^h z[r(z)]^2 dz = \frac{1}{12}h^2(R_1^2 + 2R_1R_2 + 3R_2^2). \quad (7)$$

The CENTROID is then given by

$$\bar{z} = \frac{\langle z \rangle}{V} = \frac{h(R_1^2 + R_1R_2 + R_2^2)}{4(R_1^2 + 2R_1R_2 + 3R_2^2)} \quad (8)$$

(Beyer 1987, p. 133). The special case of the CONE is given by taking  $R_2 = 0$ , yielding  $\bar{z} = h/4$ .

### Conical Function

Functions which can be expressed in terms of LEGENDRE FUNCTIONS OF THE FIRST and SECOND KINDS. See Abramowitz and Stegun (1972, p. 337).

$$P_{-1/2+ip}^{\mu}(\cos \theta) = 1 + \frac{4p^2 + 1^2}{2^2} \sin^2(\tfrac{1}{2}\theta) + \frac{(4p^2 + 1^2)(4p^2 + 3^2)}{2^2 4^2} \sin^4(\tfrac{1}{2}\theta) + \dots$$

$$= \frac{2}{\pi} \int_0^{\theta} \frac{\cosh(pt) dt}{\sqrt{2(\cos t - \cos \theta)}}$$

$$Q_{-1/2+ip}^{\mu}(\cos \theta) = \pm i \sinh(p\pi) \int_0^{\infty} \frac{\cos(pt) dt}{\sqrt{2(\cosh t + \cos \theta)}} + \int_0^{\infty} \frac{\cosh(pt) dt}{\sqrt{2(\cos t - \cos \theta)}}.$$

see also TOROIDAL FUNCTION

### Conical Spiral

A surface modeled after the shape of a SEASHELL. One parameterization (left figure) is given by

$$x = 2[1 - e^{u/(6\pi)}] \cos u \cos^2(\tfrac{1}{2}v) \quad (1)$$

$$y = 2[-1 + e^{u/(6\pi)}] \cos^2(\tfrac{1}{2}v) \sin u \quad (2)$$

$$z = 1 - e^{u/(3\pi)} - \sin v + e^{u/(6\pi)} \sin v, \quad (3)$$

where  $v \in [0, 2\pi)$ , and  $u \in [0, 6\pi)$  (Wolfram). Nordstrand gives the parameterization

$$x = \left[ \left( 1 - \frac{v}{2\pi} \right) (1 + \cos u) + c \right] \cos(nv) \quad (4)$$

$$y = \left[ \left( 1 - \frac{v}{2\pi} \right) (1 + \cos u) + c \right] \sin(nv) \quad (5)$$

$$z = \frac{bv}{2\pi} + a \sin u \left( 1 - \frac{v}{2\pi} \right) \quad (6)$$

for  $u, v \in [0, 2\pi]$  (right figure with  $a = 0.2$ ,  $b = 1$ ,  $c = 0.1$ , and  $n = 2$ ).

### Conjugacy Class

A complete set of mutually conjugate GROUP elements. Each element in a GROUP belongs to exactly one class, and the identity ( $I = 1$ ) element is always in its own class. The ORDERS of all classes must be integral FACTORS of the ORDER of the GROUP. From the last two statements, a GROUP of PRIME order has one class for each element. More generally, in an ABELIAN GROUP, each element is in a conjugacy class by itself. Two operations belong to the same class when one may be replaced by the other in a new COORDINATE SYSTEM which is accessible by a symmetry operation (Cotton 1990, p. 52). These sets correspond directly to the sets of equivalent operation.

Let  $G$  be a FINITE GROUP of ORDER  $|G|$ . If  $|G|$  is ODD, then

$$|G| \equiv s \pmod{16}$$

(Burnside 1955, p. 295). Furthermore, if every PRIME  $p_i$  DIVIDING  $|G|$  satisfies  $p_i \equiv 1 \pmod{4}$ , then

$$|G| \equiv s \pmod{32}$$

(Burnside 1955, p. 320). Poonen (1995) showed that if every PRIME  $p_i$  DIVIDING  $|G|$  satisfies  $p_i \equiv 1 \pmod{m}$  for  $m \geq 2$ , then

$$|G| \equiv s \pmod{2m^2}.$$

### Conjugate Element

Given a GROUP with elements  $A$  and  $X$ , there must be an element  $B$  which is a SIMILARITY TRANSFORMATION of  $A$ ,  $B = X^{-1}AX$  so  $A$  and  $B$  are conjugate with respect to  $X$ . Conjugate elements have the following properties:

1. Every element is conjugate with itself.
2. If  $A$  is conjugate with  $B$  with respect to  $X$ , then  $B$  is conjugate to  $A$  with respect to  $X$ .
3. If  $A$  is conjugate with  $B$  and  $C$ , then  $B$  and  $C$  are conjugate with each other.

see also CONJUGACY CLASS, CONJUGATE SUBGROUP

### Conjugate Gradient Method

An ALGORITHM for calculating the GRADIENT  $\nabla f(\mathbf{P})$  of a function at an  $n$ -D point  $\mathbf{P}$ . It is more robust than the simpler STEEPEST DESCENT METHOD.

### Conjugate Points

see HARMONIC CONJUGATE POINTS, ISOGONAL CONJUGATE, ISOTOMIC CONJUGATE POINT

### Conjugate Subgroup

A SUBGROUP  $H$  of an original GROUP  $G$  has elements  $h_i$ . Let  $x$  be a fixed element of the original GROUP  $G$  which is not a member of  $H$ . Then the transformation  $xh_ix^{-1}$ , ( $i = 1, 2, \dots$ ) generates a conjugate SUBGROUP  $xHx^{-1}$ . If, for all  $x$ ,  $xHx^{-1} = H$ , then  $H$  is a SELF-CONJUGATE (also called INVARIANT or NORMAL) SUBGROUP. All SUBGROUPS of an ABELIAN GROUP are invariant.

### Conjugation

A type I MARKOV MOVE.

see also MARKOV MOVES, STABILIZATION

### Conjunction

A product of ANDs, denoted

$$\bigwedge_{k=1}^n A_k.$$

see also AND, DISJUNCTION

### Connected Graph

A GRAPH which is connected (as a TOPOLOGICAL SPACE), i.e., there is a path from any point to any other point in the GRAPH. The number of  $n$ -VERTEX (unlabeled) connected graphs for  $n = 1, 2, \dots$  are 1, 1, 2, 6, 21, 112, 853, 11117, ... (Sloane's A001349).

#### References

- Chartrand, G. "Connected Graphs." §2.3 in *Introductory Graph Theory*. New York: Dover, pp. 41–45, 1985.  
 Sloane, N. J. A. Sequence A001349/M1657 in "An On-Line Version of the Encyclopedia of Integer Sequences."

### Connected Set

A connected set is a SET which cannot be partitioned into two nonempty SUBSETS which are open in the relative topology induced on the SET. Equivalently, it is a SET which cannot be partitioned into two nonempty SUBSETS such that each SUBSET has no points in common with the closure of the other.

The REAL NUMBERS are a connected set.

see also CLOSED SET, EMPTY SET, OPEN SET, SET, SUBSET

### Connected Space

A SPACE  $D$  is connected if any two points in  $D$  can be connected by a curve lying wholly within  $D$ . A SPACE is 0-connected (a.k.a. PATHWISE-CONNECTED) if every MAP from a 0-SPHERE to the SPACE extends continuously to the 1-DISK. Since the 0-SPHERE is the two endpoints of an interval (1-DISK), every two points have a path between them. A space is 1-connected (a.k.a. SIMPLY CONNECTED) if it is 0-connected and if every MAP from the 1-SPHERE to it extends continuously to a MAP from the 2-DISK. In other words, every loop in the SPACE is contractible. A SPACE is  $n$ -MULTIPLY CONNECTED if it is  $(n - 1)$ -connected and if every MAP from the  $n$ -SPHERE into it extends continuously over the  $(n + 1)$ -DISK.

A theorem of Whitehead says that a SPACE is infinitely connected IFF it is contractible.

see also CONNECTIVITY, LOCALLY PATHWISE-CONNECTED SPACE, MULTIPLY CONNECTED, PATHWISE-CONNECTED, SIMPLY CONNECTED

### Connected Sum

The connected sum  $M_1 \# M_2$  of  $n$ -manifolds  $M_1$  and  $M_2$  is formed by deleting the interiors of  $n$ -BALLS  $B_i^n$  in  $M_i^n$  and attaching the resulting punctured MANIFOLDS  $M_i - \dot{B}_i$  to each other by a HOMEOMORPHISM  $h : \partial B_2 \rightarrow \partial B_1$ , so

$$M_1 \# M_2 = (M_1 - \dot{B}_1) \bigcup_h (M_2 - \dot{B}_2).$$

$B_i$  is required to be interior to  $M_i$  and  $\partial B_i$  bicollared in  $M_i$  to ensure that the connected sum is a MANIFOLD.

The connected sum of two KNOTS is called a KNOT SUM. see also KNOT SUM

### Connected Sum Decomposition

Every COMPACT 3-MANIFOLD is the CONNECTED SUM of a unique collection of PRIME 3-MANIFOLDS.

see also JACO-SHALEN-JOHANNSSON TORUS DECOMPOSITION

### Connection

see CONNECTION COEFFICIENT, GAUSS-MANIN CONNECTION

### Connection Coefficient

A quantity also known as a CHRISTOFFEL SYMBOL OF THE SECOND KIND. Connection COEFFICIENTS are defined by

$$\Gamma_{\vec{e}_\beta \vec{e}_\gamma}^{\vec{e}_\alpha} \equiv \vec{e}^\alpha \cdot (\nabla_{\vec{e}_\gamma} \vec{e}_\beta) \quad (1)$$

(long form) or

$$\Gamma_{\beta\gamma}^\alpha \equiv \vec{e}^\alpha \cdot (\nabla_\gamma \vec{e}_\beta), \quad (2)$$

(abbreviated form), and satisfy

$$\nabla_{\vec{e}_\gamma} \vec{e}_\beta = \Gamma_{\vec{e}_\beta \vec{e}_\gamma}^{\vec{e}_\alpha} \vec{e}_\alpha \quad (3)$$

(long form) and

$$\nabla_\gamma \vec{e}_\beta = \Gamma_{\beta\gamma}^\alpha \vec{e}_\alpha \quad (4)$$

(abbreviated form).

Connection COEFFICIENTS are not TENSORS, but have TENSOR-like CONTRAVARIANT and COVARIANT indices. A fully COVARIANT connection COEFFICIENT is given by

$$\Gamma_{\alpha\beta\gamma} \equiv \frac{1}{2}(g_{\alpha\beta,\gamma} + g_{\alpha\gamma,\beta} + c_{\alpha\beta\gamma} + c_{\alpha\gamma\beta} - c_{\beta\gamma\alpha}), \quad (5)$$

where the  $g$ s are the METRIC TENSORS, the  $c$ s are COMMUTATION COEFFICIENTS, and the commas indicate the

COMMA DERIVATIVE. In an ORTHONORMAL BASIS,  $g_{\alpha\beta,\gamma} = 0$  and  $g_{\mu\gamma} = \delta_{\mu\gamma}$ , so

$$\Gamma_{\alpha\beta\gamma} = \Gamma_{\alpha\beta}^{\mu} g_{\mu\gamma} = \Gamma_{\alpha\beta}^{\mu} = \frac{1}{2}(c_{\alpha\beta\gamma} + c_{\alpha\gamma\beta} - c_{\beta\gamma\alpha}) \quad (6)$$

and

$$\Gamma_{ijk} = 0 \quad \text{for } i \neq j \neq k \quad (7)$$

$$\Gamma_{iik} = -\frac{1}{2} \frac{\partial g_{ii}}{\partial x^k} \quad \text{for } i \neq k \quad (8)$$

$$\Gamma_{iji} = \Gamma_{jii} = \frac{1}{2} \frac{\partial g_{ii}}{\partial x^j} \quad (9)$$

$$\Gamma_{ij}^k = 0 \quad \text{for } i \neq j \neq k \quad (10)$$

$$\Gamma_{ii}^k = -\frac{1}{2g_{kk}} \frac{\partial g_{ii}}{\partial x^k} \quad \text{for } i \neq k \quad (11)$$

$$\Gamma_{ij}^i = \Gamma_{jii}^i = \frac{1}{2g_{ii}} \frac{\partial g_{ii}}{\partial x^j} = \frac{1}{2} \frac{\partial \ln g_{ii}}{\partial x^j}. \quad (12)$$

For TENSORS of RANK 3, the connection COEFFICIENTS may be concisely summarized in MATRIX form:

$$\Gamma^{\theta} \equiv \begin{bmatrix} \Gamma_{rr}^{\theta} & \Gamma_{r\theta}^{\theta} & \Gamma_{r\phi}^{\theta} \\ \Gamma_{\theta r}^{\theta} & \Gamma_{\theta\theta}^{\theta} & \Gamma_{\theta\phi}^{\theta} \\ \Gamma_{\phi r}^{\theta} & \Gamma_{\phi\theta}^{\theta} & \Gamma_{\phi\phi}^{\theta} \end{bmatrix}. \quad (13)$$

Connection COEFFICIENTS arise in the computation of GEODESICS. The GEODESIC EQUATION of free motion is

$$d\tau^2 = -\eta_{\alpha\beta} d\xi^{\alpha} d\xi^{\beta}, \quad (14)$$

or

$$\frac{d^2 \xi^{\alpha}}{d\tau^2} = 0. \quad (15)$$

Expanding,

$$\frac{d}{d\tau} \left( \frac{\partial \xi^{\alpha}}{\partial x^{\mu}} \frac{dx^{\mu}}{d\tau} \right) = \frac{\partial \xi^{\alpha}}{\partial x^{\mu}} \frac{d^2 x^{\mu}}{d\tau^2} + \frac{\partial^2 \xi^{\alpha}}{\partial x^{\mu} \partial x^{\nu}} \frac{dx^{\mu}}{d\tau} \frac{dx^{\nu}}{d\tau} = 0 \quad (16)$$

$$\frac{\partial \xi^{\alpha}}{\partial x^{\mu}} \frac{d^2 x^{\mu}}{d\tau^2} \frac{\partial x^{\lambda}}{\partial \xi^{\alpha}} + \frac{\partial^2 \xi^{\alpha}}{\partial x^{\mu} \partial x^{\nu}} \frac{dx^{\mu}}{d\tau} \frac{dx^{\nu}}{d\tau} \frac{\partial x^{\lambda}}{\partial \xi^{\alpha}} = 0. \quad (17)$$

But

$$\frac{\partial \xi^{\alpha}}{\partial x^{\nu}} \frac{\partial x^{\lambda}}{\partial \xi^{\alpha}} = \delta_{\nu}^{\lambda}, \quad (18)$$

so

$$\begin{aligned} \delta_{\mu}^{\lambda} \frac{d^2 x^{\mu}}{d\tau^2} + \left[ \frac{\partial^2 \xi^{\alpha}}{\partial x^{\mu} \partial x^{\nu}} \frac{\partial x^{\lambda}}{\partial \xi^{\alpha}} \right] \frac{dx^{\mu}}{d\tau} \frac{dx^{\nu}}{d\tau} \\ = \frac{d^2 x^{\lambda}}{d\tau^2} + \Gamma_{\mu\nu}^{\lambda} \frac{dx^{\mu}}{d\tau} \frac{dx^{\nu}}{d\tau}, \end{aligned} \quad (19)$$

where

$$\Gamma_{\mu\nu}^{\lambda} \equiv \frac{\partial^2 \xi^{\alpha}}{\partial x^{\mu} \partial x^{\nu}} \frac{\partial x^{\lambda}}{\partial \xi^{\alpha}}. \quad (20)$$

see CONICAL WEDGE

## Conoid

see PLÜCKER'S CONOID, RIGHT CONOID

## Consecutive Number Sequences

Consecutive number sequences are sequences constructed by concatenating numbers of a given type. Many of these sequences were considered by Smarandache, so they are sometimes known as SMARANDACHE SEQUENCES.

The  $n$ th term of the consecutive integer sequence consists of the concatenation of the first  $n$  POSITIVE integers: 1, 12, 123, 1234, ... (Sloane's A007908; Smarandache 1993, Dumitrescu and Seleacu 1994, sequence 1; Mudge 1995; Stephen 1998). This sequence gives the digits of the CHAMPERNOWNE CONSTANT and contains no PRIMES in the first 4,470 terms (Weisstein). This is roughly consistent with simple arguments based on the distribution of prime which suggest that only a single prime is expected in the first 15,000 or so terms. The number of digits of the  $n$  term can be computed by noticing the pattern in the following table, where  $d = \lfloor \log_{10} n \rfloor + 1$  is the number of digits in  $n$ .

$d$	$n$ Range	Digits
1	1–9	$n$
2	10–99	$9 + 2(n - 9)$
3	100–999	$9 + 90 \cdot 2 + 3(n - 99)$
4	1000–9999	$9 + 90 \cdot 2 + 900 \cdot 3 + 4(n - 999)$

Therefore, the number of digits  $D(n)$  in the  $n$ th term can be written

$$\begin{aligned} D(n) &= d(n+1 - 10^{d-1}) + \sum_{k=1}^{d-1} 9k \cdot 10^{k-1} \\ &= (n+1)d - \frac{10^d - 1}{9}, \end{aligned}$$

where the second term is the REPUNIT  $R_d$ .

The  $n$ th term of the reverse integer sequence consists of the concatenation of the first  $n$  POSITIVE integers written backwards: 1, 21, 321, 4321, ... (Sloane's A000422; Smarandache 1993, Dumitrescu and Seleacu 1994, Stephen 1998). The only PRIME in the first 3,576 terms (Weisstein) of this sequence is the 82nd term 828180...321 (Stephen 1998), which has 155 digits. This is roughly consistent with simple arguments based on the distribution of prime which suggest that a single prime is expected in the first 15,000 or so terms. The terms of the reverse integer sequence have the same number of digits as do the consecutive integer sequence.

The concatenation of the first  $n$  PRIMES gives 2, 23, 235, 2357, 235711, ... (Sloane's A019518; Smith 1996, Mudge 1997). This sequence converges to the digits of the COPELAND-ERDŐS CONSTANT and is PRIME for terms 1, 2, 4, 128, 174, 342, 435, 1429, ... (Sloane's A046035; Ibstedt 1998, pp. 78–79), with no others less than 2,305 (Weisstein).

The concatenation of the first  $n$  ODD NUMBERS gives 1, 13, 135, 1357, 13579, ... (Sloane's A019519; Smith 1996, Marimutha 1997, Mudge 1997). This sequence is PRIME for terms 2, 10, 16, 34, 49, 2570, ... (Sloane's A046036; Weisstein, Ibstedt 1998, pp. 75–76), with no others less than 2,650 (Weisstein). The 2570th term, given by 1 3 5 7...5137 5139, has 9725 digits and was discovered by Weisstein in Aug. 1998.

The concatenation of the first  $n$  EVEN NUMBERS gives 2, 24, 246, 2468, 246810, ... (Sloane's A019520; Smith 1996; Marimutha 1997; Mudge 1997; Ibstedt 1998, pp. 77–78).

The concatenation of the first  $n$  SQUARE NUMBERS gives 1, 14, 149, 14916, ... (Sloane's A019521; Marimutha 1997). The only PRIME in the first 2,090 terms is the third term, 149, (Weisstein).

The concatenation of the first  $n$  CUBIC NUMBERS gives 1, 18, 1827, 182764, ... (Sloane's A019522; Marimutha 1997). There are no PRIMES in the first 1,830 terms (Weisstein).

see also CHAMPERNOWNE CONSTANT, CONCATENATION, COPELAND-ERDŐS CONSTANT, CUBIC NUMBER, DEMLO NUMBER, EVEN NUMBER, ODD NUMBER, SMARANDACHE SEQUENCES, SQUARE NUMBER

## Conservation of Number Principle

A generalization of Poncelet's PERMANENCE OF MATHEMATICAL RELATIONS PRINCIPLE made by H. Schubert in 1874–79. The conservation of number principle asserts that the number of solutions of any determinate algebraic problem in any number of parameters under variation of the parameters is invariant in such a manner that no solutions become INFINITE. Schubert called the application of this technique the CALCULUS of ENUMERATIVE GEOMETRY.

see also DUALITY PRINCIPLE, HILBERT'S PROBLEMS, PERMANENCE OF MATHEMATICAL RELATIONS PRINCIPLE

## References

## Conservative Field

The following conditions are equivalent for a conservative VECTOR FIELD:

1. For any oriented simple closed curve  $C$ , the LINE INTEGRAL  $\oint_C \mathbf{F} \cdot d\mathbf{s} = 0$ .
2. For any two oriented simple curves  $C_1$  and  $C_2$  with the same endpoints,  $\int_{C_1} \mathbf{F} \cdot d\mathbf{s} = \int_{C_2} \mathbf{F} \cdot d\mathbf{s}$ .
3. There exists a SCALAR POTENTIAL FUNCTION  $f$  such that  $\mathbf{F} = \nabla f$ , where  $\nabla$  is the GRADIENT.
4. The CURL  $\nabla \times \mathbf{F} = \mathbf{0}$ .

see also CURL, GRADIENT, LINE INTEGRAL, POTENTIAL FUNCTION, VECTOR FIELD

## Consistency

The absence of contradiction (i.e., the ability to prove that a statement and its NEGATIVE are both true) in an AXIOMATIC THEORY is known as consistency.

see also COMPLETE AXIOMATIC THEORY, CONSISTENCY STRENGTH

**Consistency Strength**

If the CONSISTENCY of one of two propositions implies the CONSISTENCY of the other, the first is said to have greater consistency strength.

**Constant**

Any REAL NUMBER which is “significant” (or interesting) in some way. In this work, the term “constant” is generally reserved for REAL nonintegral numbers of interest, while “NUMBER” is reserved for interesting INTEGERS (e.g., BRUN’S CONSTANT, but BEAST NUMBER).

Certain constants are known to many DECIMAL DIGITS and recur throughout many diverse areas of mathematics, often in unexpected and surprising places (e.g.,  $\pi$ ,  $e$ , and to some extent, the EULER-MASCHERONI CONSTANT  $\gamma$ ). Other constants are more specialized and may be known to only a few DIGITS. S. Plouffe maintains a site about the computation and identification of numerical constants. Plouffe’s site also contains a page giving the largest number of DIGITS computed for the most common constants. S. Finch maintains a delightful, more expository site containing detailed essays and references on constants both common and obscure.

**Constant Function**

A FUNCTION  $f(x) = c$  which does not change as its parameters vary. The GRAPH of a 1-D constant FUNCTION is a straight LINE. The DERIVATIVE of a constant FUNCTION  $c$  is

$$\frac{d}{dx} c = 0, \quad (1)$$

and the INTEGRAL is

$$\int c \, dx = cx. \quad (2)$$

The FOURIER TRANSFORM of the constant function  $f(x) = 1$  is given by

$$\mathcal{F}[1] = \int_{-\infty}^{\infty} e^{-2\pi i k x} \, dx = \delta(k), \quad (3)$$

where  $\delta(k)$  is the DELTA FUNCTION.

**Constant Problem**

Given an expression involving known constants, integration in finite terms, computation of limits, etc., determine if the expression is equal to ZERO. The constant problem is a very difficult unsolved problem in TRANSCENDENTAL NUMBER theory. However, it is known that the problem is UNDECIDABLE if the expression involves oscillatory functions such as SINE. However, the FERGUSON-FORCADE ALGORITHM is a practical algorithm for determining if there exist integers  $a_i$  for given real numbers  $x_i$  such that

$$a_1 x_1 + a_2 x_2 + \dots + a_n x_n = 0,$$

or else establish bounds within which no relation can exist (Bailey 1988).

**Constructible Number**

A number which can be represented by a FINITE number of ADDITIONS, SUBTRACTIONS, MULTIPLICATIONS, DIVISIONS, and FINITE SQUARE ROOT extractions of integers. Such numbers correspond to LINE SEGMENTS which can be constructed using only STRAIGHTEDGE and COMPASS.

All RATIONAL NUMBERS are constructible, and all constructible numbers are ALGEBRAIC NUMBERS (Courant and Robbins 1996, p. 133). If a CUBIC EQUATION with rational coefficients has no rational root, then none of its roots is constructible (Courant and Robbins, p. 136).

In particular, let  $F_0$  be the FIELD of RATIONAL NUMBERS. Now construct an extension field  $F_1$  of constructible numbers by the adjunction of  $\sqrt{k_0}$ , where  $k_0$  is in  $F_0$ , but  $\sqrt{k_0}$  is not, consisting of all numbers of the form  $a_0 + b_0 \sqrt{k_0}$ , where  $a_0, b_0 \in F_0$ . Next, construct an extension field  $F_2$  of  $F_1$  by the adjunction of  $\sqrt{k_1}$ , defined as the numbers  $a_1 + b_1 \sqrt{k_1}$ , where  $a_1, b_1 \in F_1$ , and  $k_1$  is a number in  $F_1$  for which  $\sqrt{k_1}$  does not lie in  $F_1$ . Continue the process  $n$  times. Then constructible numbers are precisely those which can be reached by such a sequence of extension fields  $F_n$ , where  $n$  is a measure of the "complexity" of the construction (Courant and Robbins 1996).

## Constructible Polygon

COMPASS and STRAIGHTEDGE constructions dating back to Euclid were capable of inscribing regular polygons of 3, 4, 5, 6, 8, 10, 12, 16, 20, 24, 32, 40, 48, 64, ..., sides. However, this listing is not a complete enumeration of "constructible" polygons. A regular  $n$ -gon ( $n \geq 3$ ) can be constructed by STRAIGHTEDGE and COMPASS IFF

$$n = 2^k p_1 p_2 \cdots p_s,$$

where  $k$  is in INTEGER  $\geq 0$  and the  $p_i$  are distinct FERMAT PRIMES. FERMAT NUMBERS are of the form

$$F_m = 2^{2^m} + 1,$$

where  $m$  is an INTEGER  $\geq 0$ . The only known PRIMES of this form are 3, 5, 17, 257, and 65537. The fact that this condition was SUFFICIENT was first proved by Gauss in 1796 when he was 19 years old. That this condition was also NECESSARY was not explicitly proven by Gauss, and the first proof of this fact is credited to Wantzel (1836).

## Construction

see GEOMETRIC CONSTRUCTION

## Constructive Dilemma

A formal argument in LOGIC in which it is stated that (1)  $P \Rightarrow Q$  and  $R \Rightarrow S$  (where  $\Rightarrow$  means "IMPLIES"), and (2) either  $P$  or  $R$  is true, from which two statements it follows that either  $Q$  or  $S$  is true.

see also DESTRUCTIVE DILEMMA, DILEMMA

## Contact Angle

The ANGLE  $\alpha$  between the normal vector of a SPHERE (or other geometric object) at a point where a PLANE is tangent to it and the normal vector of the plane. In the above figure,

$$\alpha = \cos^{-1} \left( \frac{a}{R} \right) \\ = \sin^{-1} \left( \frac{R-h}{R} \right).$$

see also SPHERICAL CAP

## Contact Number

see KISSING NUMBER

## Contact Triangle

The TRIANGLE formed by the points of intersection of a TRIANGLE  $T$ 's INCIRCLE with  $T$ . This is the PEDAL TRIANGLE of  $T$  with the INCENTER as the PEDAL POINT (c.f., TANGENTIAL TRIANGLE). The contact triangle

and TANGENTIAL TRIANGLE are perspective from the GERGONNE POINT.

#### Continued Fraction

A "general" continued fraction representation of a REAL NUMBER  $x$  is of the form

$$x = b_0 + \frac{a_1}{b_1 + \frac{a_2}{b_2 + \frac{a_3}{b_3 + \dots}}}, \quad (1)$$

which can be written

$$x = b_0 + \frac{a_1}{b_1 +} \frac{a_2}{b_2 +} \dots \quad (2)$$

The SIMPLE CONTINUED FRACTION representation of  $x$  (which is usually what is meant when the term "continued fraction" is used without qualification) of a number is given by

$$x = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \dots}}}, \quad (3)$$

which can be written in a compact abbreviated NOTATION as

$$x = [a_0, a_1, a_2, a_3, \dots]. \quad (4)$$

Here,

$$a_0 = [x] \quad (5)$$

is the integral part of  $\sigma$  (where  $[x]$  is the FLOOR FUNCTION),

$$a_1 = \left\lfloor \frac{1}{x - a_0} \right\rfloor \quad (6)$$

is the integral part of the RECIPROCAL of  $x - a_0$ ,  $a_2$  is the integral part of the reciprocal of the remainder, etc. The quantities  $a_i$  are called PARTIAL QUOTIENTS. An archaic word for a continued fraction is ANTHYPHAIRETIC RATIO.

Continued fractions provide, in some sense, a series of "best" estimates for an IRRATIONAL NUMBER. Functions can also be written as continued fractions, providing a series of better and better rational approximations. Continued fractions have also proved useful in the proof of certain properties of numbers such as  $e$  and  $\pi$  (PI). Because irrationals which are square roots of RATIONAL NUMBERS have periodic continued fractions, an exact representation for a tabulated numerical value (i.e., 1.414... for PYTHAGORAS'S CONSTANT,  $\sqrt{2}$ ) can sometimes be found.

Continued fractions are also useful for finding near commensurabilities between events with different periods. For example, the Metonic cycle used for calendrical purposes by the Greeks consists of 235 lunar months which very nearly equal 19 solar years, and  $235/19$  is the sixth CONVERGENT of the ratio of the lunar phase (synodic) period and solar period ( $365.2425/29.53059$ ). Continued fractions can also be used to calculate gear ratios, and were used for this purpose by the ancient Greeks (Guy 1990).

If only the first few terms of a continued fraction are kept, the result is called a CONVERGENT. Let  $P_n/Q_n$  be convergents of a nonsimple continued fraction. Then

$$P_{-1} \equiv 1 \quad Q_{-1} \equiv 0 \quad (7)$$

$$P_0 \equiv b_0 \quad Q_0 \equiv 1 \quad (8)$$

and subsequent terms are calculated from the RECURRENT RELATIONS

$$P_j = b_j P_{j-1} + a_j P_{j-2} \quad (9)$$

$$Q_j = b_j Q_{j-1} + a_j Q_{j-2} \quad (10)$$

for  $j = 1, 2, \dots, n$ . It is also true that

$$P_n Q_{n-1} - P_{n-1} Q_n = (-1)^{n-1} \prod_{k=1}^n a_k. \quad (11)$$

The error in approximating a number by a given CONVERGENT is roughly the MULTIPLICATIVE INVERSE of the square of the DENOMINATOR of the first neglected term.

A *finite simple* continued fraction representation terminates after a finite number of terms. To "round" a continued fraction, truncate the last term unless it is  $\pm 1$ ,

in which case it should be added to the previous term (Beeler *et al.* 1972, Item 101A). To take one over a continued fraction, add (or possibly delete) an initial 0 term. To negate, take the NEGATIVE of all terms, optionally using the identity

$$[-a, -b, -c, -d, \dots] = [-a - 1, 1, b - 1, c, d, \dots]. \quad (12)$$

A particularly beautiful identity involving the terms of the continued fraction is

$$\frac{[a_0, a_1, \dots, a_n]}{[a_0, a_1, \dots, a_{n-1}]} = \frac{[a_n, a_{n-1}, \dots, a_1, a_0]}{[a_n, a_{n-1}, \dots, a_1]}. \quad (13)$$

Finite simple fractions represent rational numbers and all rational numbers are represented by finite continued fractions. There are two possible representations for a finite simple fraction:

$$[a_1, \dots, a_n] = \begin{cases} [a_1, \dots, a_{n-1}, a_n - 1, 1] & \text{for } a_n > 1 \\ [a_1, \dots, a_{n-2}, a_{n-1} + 1] & \text{for } a_n = 1. \end{cases} \quad (14)$$

On the other hand, an infinite simple fraction represents a unique IRRATIONAL NUMBER, and each IRRATIONAL NUMBER has a unique infinite continued fraction.

Consider the CONVERGENTS  $p_n/q_n$  of a *simple* continued fraction, and define

$$p_{-1} \equiv 0 \quad q_{-1} \equiv 1 \quad (15)$$

$$p_0 \equiv 1 \quad q_0 \equiv 0 \quad (16)$$

$$p_1 \equiv a_1 \quad q_1 \equiv 1. \quad (17)$$

Then subsequent terms can be calculated from the RECURRENCE RELATIONS

$$p_i = a_i p_{i-1} + p_{i-2} \quad (18)$$

$$q_i = a_i q_{i-1} + q_{i-2}. \quad (19)$$

The CONTINUED FRACTION FUNDAMENTAL RECURRENCE RELATION for *simple* continued fractions is

$$p_n q_{n-1} - p_{n-1} q_n = (-1)^n. \quad (20)$$

It is also true that if  $a_1 \neq 0$ ,

$$\frac{p_n}{p_{n-1}} = [a_n, a_{n-1}, \dots, a_1] \quad (21)$$

$$\frac{q_n}{q_{n-1}} = [a_n, \dots, a_2]. \quad (22)$$

Furthermore,

$$\frac{p_n}{q_n} = \frac{p_{n+1} - p_{n-1}}{q_{n+1} - q_{n-1}} \quad (23)$$

$$p_n = (n-1)p_{n-1} + (n-1)p_{n-2} + (n-2)p_{n-3} + \dots + 3p_2 + 2p_1 + p_1 + 1. \quad (24)$$

Also, if  $p/q > 1$  and

$$\frac{p}{q} = [a_1, a_2, \dots, a_n], \quad (25)$$

then

$$\frac{q}{p} = [0, a_1, \dots, a_n]. \quad (26)$$

Similarly, if  $p/q < 1$  so

$$\frac{p}{q} = [0, a_1, \dots, a_n], \quad (27)$$

then

$$\frac{q}{p} = [a_1, \dots, a_n]. \quad (28)$$

The convergents also satisfy

$$c_n - c_{n-1} = \frac{(-1)^n}{q_n q_{n-1}} \quad (29)$$

$$c_n - c_{n-2} = \frac{a_n (-1)^{n-1}}{q_n q_{n-2}}. \quad (30)$$

The ODD convergents  $c_{2n+1}$  of an infinite simple continued fraction form an INCREASING SEQUENCE, and the EVEN convergents  $c_{2n}$  form a DECREASING SEQUENCE (so any ODD convergent is less than any EVEN convergent). Summarizing,

$$c_1 < c_3 < c_5 < \dots < c_{2n+1} < \dots < c_{2n} < \dots < c_6 < c_4 < c_2. \quad (31)$$

Furthermore, each convergent for  $n \geq 3$  lies between the two preceding ones. Each convergent is nearer to the value of the infinite continued fraction than the previous one. Let  $p_n/q_n$  be the  $n$ th continued fraction representation. Then

$$\frac{1}{(a_{n+1} + 2)q_n^2} < \left| \sigma - \frac{p_n}{q_n} \right| < \frac{1}{a_{n+1}q_n^2}. \quad (32)$$

The SQUARE ROOT of a SQUAREFREE INTEGER has a periodic continued fraction of the form

$$\sqrt{n} = [a_1, \overline{a_2, \dots, a_n, 2a_1}] \quad (33)$$

(Rose 1994, p. 130). Furthermore, if  $D$  is not a SQUARE NUMBER, then the terms of the continued fraction of  $\sqrt{D}$  satisfy

$$0 < a_n < 2\sqrt{D}. \quad (34)$$

In particular,

$$[\bar{a}] = \frac{a + \sqrt{a^2 + 4}}{2} \quad (35)$$

$$[1, \bar{a}] = \frac{-1 + \sqrt{1 + 4a}}{2} \quad (36)$$

$$[a, 2a] = \sqrt{a^2 + 1} \quad (37)$$

$$[\overline{ac}, \bar{a}] = \frac{b + \sqrt{b^2 + 4c}}{2} \quad (38)$$

$$\begin{aligned} & [a_1, \dots, a_n] \\ &= \frac{-(q_{n-1} - p_n) + \sqrt{(q_{n-1} - p_n)^2 + 4q_n p_{n-1}}}{2q_n} \end{aligned} \quad (39)$$

$$[a_1, \overline{b_1, \dots, b_n}] = a_1 + \frac{1}{[b_1, \dots, b_n]} \quad (40)$$

$$[\overline{b_1, \dots, b_n}] = \frac{[b_1, \dots, b_n]p_n + p_{n-1}}{[b_1, \dots, b_n]q_n + q_{n-1}}. \quad (41)$$

The first follows from

$$\begin{aligned} \alpha &= n + \frac{1}{n + \frac{1}{n + \frac{1}{n + \dots}}} \\ &= n + \frac{1}{n + \left( \frac{1}{n + \frac{1}{n + \dots}} \right)}. \end{aligned} \quad (42)$$

Therefore,

$$\alpha - n = \frac{1}{n + \frac{1}{n + \frac{1}{n + \dots}}}, \quad (43)$$

so plugging (43) into (42) gives

$$\alpha = n + \frac{1}{n + (\alpha - n)} = n + \frac{1}{\alpha}. \quad (44)$$

Expanding

$$\alpha^2 - n\alpha - 1 = 0, \quad (45)$$

and solving using the QUADRATIC FORMULA gives

$$\alpha = \frac{n + \sqrt{n^2 + 4}}{2}. \quad (46)$$

The analog of this treatment in the general case gives

$$\alpha = \frac{\alpha p_n + p_{n-1}}{\alpha q_n + q_{n-1}}. \quad (47)$$

The following table gives the repeating simple continued fractions for the square roots of the first few integers (excluding the trivial SQUARE NUMBERS).

$N$	$\alpha_{\sqrt{N}}$	$N$	$\alpha_{\sqrt{N}}$
2	$[1, \overline{2}]$	22	$[4, \overline{1, 2, 4, 2, 1, 8}]$
3	$[1, \overline{1, 2}]$	23	$[4, \overline{1, 3, 1, 8}]$
5	$[2, \overline{4}]$	24	$[4, \overline{1, 8}]$
6	$[2, \overline{2, 4}]$	26	$[5, \overline{10}]$
7	$[2, \overline{1, 1, 4}]$	27	$[5, \overline{5, 10}]$
8	$[2, \overline{1, 4}]$	28	$[5, \overline{3, 2, 3, 10}]$
10	$[3, \overline{6}]$	29	$[5, \overline{2, 1, 1, 2, 10}]$
11	$[3, \overline{3, 6}]$	30	$[5, \overline{2, 10}]$
12	$[3, \overline{2, 6}]$	31	$[5, \overline{1, 1, 3, 5, 3, 1, 1, 10}]$
13	$[3, \overline{1, 1, 1, 1, 6}]$	32	$[5, \overline{1, 1, 1, 10}]$
14	$[3, \overline{1, 2, 1, 6}]$	33	$[5, \overline{1, 2, 1, 10}]$
15	$[3, \overline{1, 6}]$	34	$[5, \overline{1, 4, 1, 10}]$
17	$[4, \overline{8}]$	35	$[5, \overline{1, 10}]$
18	$[4, \overline{4, 8}]$	37	$[6, \overline{12}]$
19	$[4, \overline{2, 1, 3, 1, 2, 8}]$	38	$[6, \overline{6, 12}]$
20	$[4, \overline{2, 8}]$	39	$[6, \overline{4, 12}]$
21	$[4, \overline{1, 1, 2, 1, 1, 8}]$	40	$[6, \overline{3, 12}]$

The periods of the continued fractions of the square roots of the first few nonsquare integers 2, 3, 5, 6, 7, 8, 10, 11, 12, 13, ... (Sloane's A000037) are 1, 2, 1, 2, 4, 2, 1, 2, 2, 5, ... (Sloane's A013943; Williams 1981, Jacobson *et al.* 1995). An upper bound for the length is roughly  $\mathcal{O}(\ln D\sqrt{D})$ .

An even stronger result is that a continued fraction is periodic IFF it is a ROOT of a quadratic POLYNOMIAL. Calling the portion of a number  $x$  remaining after a given convergent the "tail," it must be true that the relationship between the number  $x$  and terms in its tail is of the form

$$x = \frac{ax + b}{cd + d}, \quad (48)$$

which can only lead to a QUADRATIC EQUATION.

LOGARITHMS  $\log_{b_0} b_1$  can be computed by defining  $b_2$ , ... and the POSITIVE INTEGER  $n_1, \dots$  such that

$$b_1^{n_1} < b_0 < b_1^{n_1+1} \quad b_2 = \frac{b_0}{b_1^{n_1}} \quad (49)$$

$$b_2^{n_2} < b_1 < b_2^{n_2+1} \quad b_3 = \frac{b_1}{b_2^{n_2}} \quad (50)$$

and so on. Then

$$\log_{b_0} b_1 = [n_1, n_2, n_3, \dots]. \quad (51)$$

A geometric interpretation for a reduced FRACTION  $y/x$  consists of a string through a LATTICE of points with ends at  $(1, 0)$  and  $(x, y)$  (Klein 1907, 1932; Steinhaus 1983; Ball and Coxeter 1987, pp. 86–87; Davenport 1992). This interpretation is closely related to a similar one for the GREATEST COMMON DIVISOR. The pegs it presses against  $(x_i, y_i)$  give alternate CONVERGENTS  $y_i/x_i$ , while the other CONVERGENTS are obtained from the pegs it presses against with the initial end at  $(0, 1)$ . The above plot is for  $e - 2$ , which has convergents 0, 1, 2/3, 3/4, 5/7, ...

Let the continued fraction for  $x$  be written  $[a_1, a_2, \dots, a_n]$ . Then the limiting value is *almost always* KHINTCHINE'S CONSTANT

$$K \equiv \lim_{n \rightarrow \infty} (a_1 a_2 \cdots a_n)^{1/n} = 2.68545 \dots \quad (52)$$

Continued fractions can be used to express the POSITIVE ROOTS of any POLYNOMIAL equation. Continued fractions can also be used to solve linear DIOPHANTINE EQUATIONS and the PELL EQUATION. Euler showed that if a CONVERGENT SERIES can be written in the form

$$c_1 + c_1 c_2 + c_1 c_2 c_3 + \dots, \quad (53)$$

then it is equal to the continued fraction

$$1 - \frac{c_1}{1 - \frac{c_2}{1 + c_2 - \frac{c_3}{1 + c_3 - \dots}}} \quad (54)$$

Gosper has invented an ALGORITHM for performing analytic ADDITION, SUBTRACTION, MULTIPLICATION, and DIVISION using continued fractions. It requires keeping track of eight INTEGERS which are conceptually arranged at the VERTICES of a CUBE. The ALGORITHM has not, however, appeared in print (Gosper 1996).

An algorithm for computing the continued fraction for  $(ax + b)/(cx + d)$  from the continued fraction for  $x$  is given by Beeler *et al.* (1972, Item 101), Knuth (1981, Exercise 4.5.3.15, pp. 360 and 601), and Fowler (1991). (In line 9 of Knuth's solution,  $X_k \leftarrow \lfloor A/C \rfloor$  should be replaced by  $X_k \leftarrow \min(\lfloor A/C \rfloor, \lfloor (A+B)/(C+D) \rfloor)$ .) Beeler *et al.* (1972) and Knuth (1981) also mention the bivariate case  $(axy + bx + cy + d)/(Axy + Bx + Cy + D)$ . *see also* GAUSSIAN BRACKETS, HURWITZ'S IRRATIONAL NUMBER THEOREM, KHINTCHINE'S CONSTANT, LAGRANGE'S CONTINUED FRACTION THEOREM, LAMÉ'S THEOREM, LÉVY CONSTANT, PADÉ APPROXIMANT, PARTIAL QUOTIENT, PI, QUADRATIC IRRATIONAL NUMBER, QUOTIENT-DIFFERENCE ALGORITHM, SEGRE'S THEOREM

### Continued Fraction Constant

A continued fraction with partial quotients which increase in ARITHMETIC PROGRESSION is

$$[A + D, A + 2D, A + 3D, \dots] = \frac{I_{A/D} \left( \frac{2}{D} \right)}{I_{1+A/D} \left( \frac{2}{D} \right)},$$

where  $I_n(x)$  is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND (Beeler *et al.* 1972, Item 99). A special case is

$$C = 0 + \frac{1}{1 + \frac{1}{2 + \frac{1}{3 + \frac{1}{4 + \frac{1}{5 + \dots}}}}},$$

which has the value

$$C = \frac{I_1(2)}{I_0(2)} = 0.697774658 \dots$$

(Lehmer 1973, Rabinowitz 1990).

### Continued Fraction Factorization Algorithm

A PRIME FACTORIZATION ALGORITHM which uses RESIDUES produced in the CONTINUED FRACTION of  $\sqrt{mN}$  for some suitably chosen  $m$  to obtain a SQUARE NUMBER. The ALGORITHM solves

$$x^2 \equiv y^2 \pmod{n}$$

by finding an  $m$  for which  $m^2 \pmod{n}$  has the smallest upper bound. The method requires (by conjecture) about  $\exp(\sqrt{2 \log n \log \log n})$  steps, and was the fastest PRIME FACTORIZATION ALGORITHM in use before the

QUADRATIC SIEVE FACTORIZATION METHOD, which eliminates the 2 under the SQUARE ROOT (Pomerance 1996), was developed.

### Continued Fraction Fundamental

#### Recurrence Relation

For a SIMPLE CONTINUED FRACTION  $\sigma = [a_0, a_1, \dots]$  with CONVERGENTS  $p_n/q_n$ , the fundamental RECURRENCE RELATION is given by

$$p_n q_{n-1} - p_{n-1} q_n = (-1)^n.$$

### Continued Fraction Map

$$f(x) = \frac{1}{x} - \left\lfloor \frac{1}{x} \right\rfloor$$

for  $x \in [0, 1]$ , where  $\lfloor x \rfloor$  is the FLOOR FUNCTION. The INVARIANT DENSITY of the map is

$$\rho(y) = \frac{1}{(1+y) \ln 2}.$$

**Continuity Correction**

A correction to a discrete BINOMIAL DISTRIBUTION to approximate a continuous distribution.

$$P(a \leq X \leq b)$$

$$\approx P\left(\frac{a - \frac{1}{2} - np}{\sqrt{np(1-p)}} \leq z \leq \frac{b - \frac{1}{2} - np}{\sqrt{np(1-p)}}\right),$$

where

$$z \equiv \frac{(x - \mu)}{\sigma}$$

is a continuous variate with a NORMAL DISTRIBUTION and  $X$  is a variate of a BINOMIAL DISTRIBUTION.

see also BINOMIAL DISTRIBUTION, NORMAL DISTRIBUTION

**Continuity Principle**

see PERMANENCE OF MATHEMATICAL RELATIONS PRINCIPLE

**Continuous**

A general mathematical property obeyed by mathematical objects in which all elements are within a NEIGHBORHOOD of nearby points.

see also ABSOLUTELY CONTINUOUS, CONTINUOUS DISTRIBUTION, CONTINUOUS FUNCTION, CONTINUOUS SPACE, JUMP

**Continuous Distribution**

A DISTRIBUTION for which the variables may take on a continuous range of values. Abramowitz and Stegun (1972, p. 930) give a table of the parameters of most common discrete distributions.

## Continuous Function

A continuous function is a FUNCTION  $f: X \rightarrow Y$  where the pre-image of every OPEN SET in  $Y$  is OPEN in  $X$ . A function  $f(x)$  in a single variable  $x$  is said to be continuous at point  $x_0$  if

1.  $f(x_0)$  is defined, so  $x_0$  is the DOMAIN of  $f$ .
2.  $\lim_{x \rightarrow x_0} f(x)$  exists.
3.  $\lim_{x \rightarrow x_0} f(x) = f(x_0)$ ,

where  $\lim$  denotes a LIMIT. If  $f$  is DIFFERENTIABLE at point  $x_0$ , then it is also continuous at  $x_0$ . If  $f$  and  $g$  are continuous at  $x_0$ , then

1.  $f + g$  is continuous at  $x_0$ .
2.  $f - g$  is continuous at  $x_0$ .
3.  $f \times g$  is continuous at  $x_0$ .
4.  $f \div g$  is continuous at  $x_0$  if  $g(x_0) \neq 0$  and is discontinuous at  $x_0$  if  $g(x_0) = 0$ .
5.  $f \circ g$  is continuous, where  $\circ$  denotes using  $g$  as the argument to  $f$ .

see also CRITICAL POINT, DIFFERENTIABLE, LIMIT, NEIGHBORHOOD, STATIONARY POINT

## Continuous Space

A TOPOLOGICAL SPACE.

see also NET

## Continuum

The nondenumerable set of REAL NUMBERS, denoted  $C$ . It satisfies

$$\aleph_0 + C = C \quad (1)$$

and

$$C^r = C, \quad (2)$$

where  $\aleph_0$  is  $\aleph_0$  (ALEPH-0). It is also true that

$$\aleph_0^{\aleph_0} = C. \quad (3)$$

However,

$$C^C = F \quad (4)$$

is a SET larger than the continuum. Paradoxically, there are exactly as many points  $C$  on a LINE (or LINE SEGMENT) as in a PLANE, a 3-D SPACE, or finite HYPER-SPACE, since all these SETS can be put into a ONE-TO-ONE correspondence with each other.

The CONTINUUM HYPOTHESIS, first proposed by Georg Cantor, holds that the CARDINAL NUMBER of the continuum is the same as that of  $\aleph_1$ . The surprising truth is that this proposition is UNDECIDABLE, since neither it nor its converse contradicts the tenets of SET THEORY.

see also ALEPH-0 ( $\aleph_0$ ), ALEPH-1 ( $\aleph_1$ ), CONTINUUM HYPOTHESIS, DENUMERABLE SET

## Continuum Hypothesis

The proposal originally made by Georg Cantor that there is no infinite SET with a CARDINAL NUMBER between that of the "small" infinite SET of INTEGERS  $\aleph_0$  and the "large" infinite set of REAL NUMBERS  $C$  (the "CONTINUUM"). Symbolically, the continuum hypothesis is that  $\aleph_1 = C$ . Gödel showed that no contradiction would arise if the continuum hypothesis was added to conventional ZERMELO-FRAENKEL SET THEORY. However, using a technique called FORCING, Paul Cohen (1963, 1964) proved that no contradiction would arise if the *negation* of the continuum hypothesis was added to SET THEORY. Together, Gödel's and Cohen's results established that the validity of the continuum hypothesis depends on the version of SET THEORY being used, and is therefore UNDECIDABLE (assuming the ZERMELO-FRAENKEL AXIOMS together with the AXIOM OF CHOICE).

Conway and Guy (1996) give a generalized version of the Continuum Hypothesis which is also UNDECIDABLE: is  $2^{\aleph_\alpha} = \aleph_{\alpha+1}$  for every  $\alpha$ ?

see also ALEPH-0 ( $\aleph_0$ ), ALEPH-1 ( $\aleph_1$ ), AXIOM OF CHOICE, CARDINAL NUMBER, CONTINUUM, DENUMERABLE SET, FORCING, HILBERT'S PROBLEMS, LEBESGUE MEASURABILITY PROBLEM, UNDECIDABLE, ZERMELO-FRAENKEL AXIOMS, ZERMELO-FRAENKEL SET THEORY

## Contour

A path in the COMPLEX PLANE over which CONTOUR INTEGRATION is performed.

see also CONTOUR INTEGRATION

## Contour Integral

see CONTOUR INTEGRATION

## Contour Integration

Let  $P(x)$  and  $Q(x)$  be POLYNOMIALS of DEGREES  $n$  and  $m$  with COEFFICIENTS  $b_n, \dots, b_0$  and  $c_m, \dots, c_0$ . Take the contour in the upper half-plane, replace  $x$  by  $z$ , and write  $z \equiv Re^{i\theta}$ . Then

$$\int_{-\infty}^{\infty} \frac{P(z) dz}{Q(z)} = \lim_{R \rightarrow \infty} \int_{-R}^R \frac{P(z) dz}{Q(z)}. \quad (1)$$

Define a path  $\gamma_R$  which is straight along the REAL axis from  $-R$  to  $R$  and makes a circular arc to connect the two ends in the upper half of the COMPLEX PLANE. The RESIDUE THEOREM then gives

$$\begin{aligned} \lim_{R \rightarrow \infty} \int_{\gamma_R} \frac{P(z) dz}{Q(z)} \\ = \lim_{R \rightarrow \infty} \int_{-R}^R \frac{P(z) dz}{Q(z)} + \lim_{R \rightarrow \infty} \int_0^\pi \frac{P(Re^{i\theta})}{Q(Re^{i\theta})} iRe^{i\theta} d\theta \\ = 2\pi i \sum_{\Im[z]>0} \text{Res} \left[ \frac{P(z)}{Q(z)} \right], \quad (2) \end{aligned}$$

where Res denotes the RESIDUES. Solving,

$$\begin{aligned} \lim_{R \rightarrow \infty} \int_{-R}^R \frac{P(z) dz}{Q(z)} \\ = 2\pi i \sum_{\Im[z]>0} \text{Res} \frac{P(z)}{Q(z)} - \lim_{R \rightarrow \infty} \int_0^\pi \frac{P(Re^{i\theta})}{Q(Re^{i\theta})} iRe^{i\theta} d\theta. \quad (3) \end{aligned}$$

Define

$$\begin{aligned} I_r &\equiv \lim_{R \rightarrow \infty} \int_0^\pi \frac{P(Re^{i\theta})}{Q(Re^{i\theta})} iRe^{i\theta} d\theta \\ &= \lim_{R \rightarrow \infty} \int_0^\pi \frac{b_n(Re^{i\theta})^n + b_{n-1}(Re^{i\theta})^{n-1} + \dots + b_0}{c_m(Re^{i\theta})^m + c_{m-1}(Re^{i\theta})^{m-1} + \dots + c_0} iR d\theta \\ &= \lim_{R \rightarrow \infty} \int_0^\pi \frac{b_n}{c_m} (Re^{i\theta})^{n-m} iR d\theta \\ &= \lim_{R \rightarrow \infty} \int_0^\pi \frac{b_n}{c_m} R^{n+1-m} i(e^{i\theta})^{n-m} d\theta \quad (4) \end{aligned}$$

and set

$$\epsilon \equiv -(n+1-m), \quad (5)$$

then equation (4) becomes

$$I_r \equiv \lim_{R \rightarrow \infty} \frac{i}{R^\epsilon} \frac{b_n}{c_m} \int_0^\pi e^{i(n-m)\theta} d\theta. \quad (6)$$

Now,

$$\lim_{R \rightarrow \infty} R^{-\epsilon} = 0 \quad (7)$$

for  $\epsilon > 0$ . That means that for  $-n-1+m \geq 1$ , or  $m \geq n+2$ ,  $I_r = 0$ , so

$$\int_{-\infty}^{\infty} \frac{P(z) dz}{Q(z)} = 2\pi i \sum_{\Im[z]>0} \text{Res} \left[ \frac{P(z)}{Q(z)} \right] \quad (8)$$

for  $m \geq n+2$ . Apply JORDAN'S LEMMA with  $f(x) \equiv P(x)/Q(x)$ . We must have

$$\lim_{x \rightarrow \infty} f(x) = 0, \quad (9)$$

so we require  $m \geq n+1$ . Then

$$\int_{-\infty}^{\infty} \frac{P(z)}{Q(z)} e^{iaz} dz = 2\pi i \sum_{\Im[z]>0} \text{Res} \left[ \frac{P(z)}{Q(z)} e^{iaz} \right] \quad (10)$$

for  $m \geq n+1$ .

Since this must hold separately for REAL and IMAGINARY PARTS, this result can be extended to

$$\int_{-\infty}^{\infty} \frac{P(x)}{Q(x)} \cos(ax) dx = 2\pi \Re \left\{ \sum_{\Im[z]>0} \text{Res} \left[ \frac{P(z)}{Q(z)} e^{iaz} \right] \right\} \quad (11)$$

$$\int_{-\infty}^{\infty} \frac{P(x)}{Q(x)} \sin(ax) dx = 2\pi \Im \left\{ \sum_{\Im[z]>0} \text{Res} \left[ \frac{P(z)}{Q(z)} e^{iaz} \right] \right\}. \quad (12)$$

It is also true that

$$\int_{-\infty}^{\infty} \frac{P(z)}{Q(z)} \ln(az) dz = 0. \quad (13)$$

#### Contracted Cycloid

see CURTATE CYCLOID

#### Contraction

see DILATION

#### Contraction (Graph)

The merging of nodes in a GRAPH by eliminating segments between two nodes.

#### Contraction (Tensor)

The contraction of a TENSOR is obtained by setting unlike indices equal and summing according to the EINSTEIN SUMMATION convention. Contraction reduces the RANK of a TENSOR by 2. For a second RANK TENSOR,

$$\text{contr}(B_j^{i_i}) \equiv B_i^{i_i}$$

$$B_i^{i_i} = \frac{\partial x'_i}{\partial x_k} \frac{\partial x_l}{\partial x'_i} B_l^k = \frac{\partial x_l}{\partial x_k} B_l^k = \delta_k^l B_l^k = B_k^k.$$

Therefore, the contraction is invariant, and must be a SCALAR. In fact, this SCALAR is known as the TRACE of a MATRIX in MATRIX theory.

### Contradiction Law

No  $A$  is not- $A$ .

see also NOT

### Contravariant Tensor

A contravariant tensor is a TENSOR having specific transformation properties (c.f., a COVARIANT TENSOR). To examine the transformation properties of a contravariant tensor, first consider a TENSOR of RANK 1 (a VECTOR)

$$d\mathbf{r} = dx_1\hat{\mathbf{x}}_1 + dx_2\hat{\mathbf{x}}_2 + dx_3\hat{\mathbf{x}}_3, \quad (1)$$

for which

$$dx'_i = \frac{\partial x'_i}{\partial x_j} dx_j. \quad (2)$$

Now let  $A_i \equiv dx_i$ , then any set of quantities  $A_j$  which transform according to

$$A'_i = \frac{\partial x'_i}{\partial x_j} A_j, \quad (3)$$

or, defining

$$a_{ij} \equiv \frac{\partial x'_i}{\partial x_j}, \quad (4)$$

according to

$$A'_i = a_{ij} A_j \quad (5)$$

is a contravariant tensor. Contravariant tensors are indicated with raised indices, i.e.,  $a^\mu$ .

COVARIANT TENSORS are a type of TENSOR with differing transformation properties, denoted  $a_\nu$ . However, in 3-D CARTESIAN COORDINATES,

$$\frac{\partial x_j}{\partial x'_i} = \frac{\partial x'_i}{\partial x_j} \equiv a_{ij} \quad (6)$$

for  $i, j = 1, 2, 3$ , meaning that contravariant and covariant tensors are equivalent. The two types of tensors do differ in higher dimensions, however. Contravariant FOUR-VECTORS satisfy

$$a^\mu = \Lambda^\mu_\nu a^\nu, \quad (7)$$

where  $\Lambda$  is a LORENTZ TENSOR.

To turn a COVARIANT TENSOR into a contravariant tensor, use the METRIC TENSOR  $g^{\mu\nu}$  to write

$$a^\mu \equiv g^{\mu\nu} a_\nu. \quad (8)$$

Covariant and contravariant indices can be used simultaneously in a MIXED TENSOR.

#### References

- Zabczyk, J. *Mathematical Control Theory: An Introduction*. Boston, MA: Birkhäuser, 1993.

### Convective Acceleration

The acceleration of an element of fluid, given by the CONVECTIVE DERIVATIVE of the VELOCITY  $\mathbf{v}$ ,

$$\frac{D\mathbf{v}}{Dt} = \frac{\partial \mathbf{v}}{\partial t} + \mathbf{v} \cdot \nabla \mathbf{v},$$

where  $\nabla$  is the GRADIENT operator.

see also ACCELERATION, CONVECTIVE DERIVATIVE, CONVECTIVE OPERATOR

#### References

- Batchelor, G K. *An Introduction to Fluid Dynamics*. Cambridge, England: Cambridge University Press, p. 73, 1977.

### Convective Derivative

A DERIVATIVE taken with respect to a moving coordinate system, also called a LAGRANGIAN DERIVATIVE. It is given by

$$\frac{D}{Dt} = \frac{\partial}{\partial t} + \mathbf{v} \cdot \nabla,$$

where  $\nabla$  is the GRADIENT operator and  $\mathbf{v}$  is the VELOCITY of the fluid. This type of derivative is especially useful in the study of fluid mechanics. When applied to  $\mathbf{v}$ ,

$$\frac{D\mathbf{v}}{Dt} = \frac{\partial \mathbf{v}}{\partial t} + (\nabla \times \mathbf{v}) \times \mathbf{v} + \nabla(\frac{1}{2} \mathbf{v}^2).$$

see also CONVECTIVE OPERATOR, DERIVATIVE, VELOCITY

#### References

### Convective Operator

Defined for a VECTOR FIELD  $\mathbf{A}$  by  $(\mathbf{A} \cdot \nabla)$ , where  $\nabla$  is the GRADIENT operator.

Applied in arbitrary orthogonal 3-D coordinates to a VECTOR FIELD  $\mathbf{B}$ , the convective operator becomes

$$[(\mathbf{A} \cdot \nabla)\mathbf{B}]_j = \sum_{k=1}^3 \left[ \frac{A_k}{h_k} \frac{\partial B_j}{\partial q_k} + \frac{B_k}{h_k h_j} \left( A_j \frac{\partial h_j}{\partial q_k} - A_k \frac{\partial h_k}{\partial q_j} \right) \right], \quad (1)$$

where the  $h_i$ s are related to the METRIC TENSORS by  $h_i = \sqrt{g_{ii}}$ . In CARTESIAN COORDINATES,

$$\begin{aligned} (\mathbf{A} \cdot \nabla) \mathbf{B} = & \left( A_x \frac{\partial B_x}{\partial x} + A_y \frac{\partial B_x}{\partial y} + A_z \frac{\partial B_x}{\partial z} \right) \hat{\mathbf{x}} \\ & + \left( A_x \frac{\partial B_y}{\partial x} + A_y \frac{\partial B_y}{\partial y} + A_z \frac{\partial B_y}{\partial z} \right) \hat{\mathbf{y}} \\ & + \left( A_x \frac{\partial B_z}{\partial x} + A_y \frac{\partial B_z}{\partial y} + A_z \frac{\partial B_z}{\partial z} \right) \hat{\mathbf{z}}. \quad (2) \end{aligned}$$

In CYLINDRICAL COORDINATES,

$$\begin{aligned} (\mathbf{A} \cdot \nabla) \mathbf{B} = & \left( A_r \frac{\partial B_r}{\partial r} + \frac{A_\phi}{r} \frac{\partial B_r}{\partial \phi} + A_z \frac{\partial B_r}{\partial z} - \frac{A_\phi B_\phi}{r} \right) \hat{\mathbf{r}} \\ & + \left( A_r \frac{\partial B_\phi}{\partial r} + \frac{A_\phi}{r} \frac{\partial B_\phi}{\partial \phi} + A_z \frac{\partial B_\phi}{\partial z} + \frac{A_\phi B_r}{r} \right) \hat{\boldsymbol{\phi}} \\ & + \left( A_r \frac{\partial B_z}{\partial r} + \frac{A_\phi}{r} \frac{\partial B_z}{\partial \phi} + A_z \frac{\partial B_z}{\partial z} \right) \hat{\mathbf{z}}. \quad (3) \end{aligned}$$

In SPHERICAL COORDINATES,

$$\begin{aligned} (\mathbf{A} \cdot \nabla) \mathbf{B} = & \left( A_r \frac{\partial B_r}{\partial r} + \frac{A_\theta}{r} \frac{\partial B_r}{\partial \theta} + \frac{A_\phi}{r \sin \theta} \frac{\partial B_r}{\partial \phi} - \frac{A_\theta B_\theta + A_\phi B_\phi}{r} \right) \hat{\mathbf{r}} \\ & + \left( A_r \frac{\partial B_\theta}{\partial r} + \frac{A_\theta}{r} \frac{\partial B_\theta}{\partial \theta} + \frac{A_\phi}{r \sin \theta} \frac{\partial B_\theta}{\partial \phi} + \frac{A_\theta B_r}{r} - \frac{A_\phi B_\phi \cot \theta}{r} \right) \hat{\boldsymbol{\theta}} \\ & + \left( A_r \frac{\partial B_\phi}{\partial r} + \frac{A_\theta}{r} \frac{\partial B_\phi}{\partial \theta} + \frac{A_\phi}{r \sin \theta} \frac{\partial B_\phi}{\partial \phi} + \frac{A_\phi B_r}{r} + \frac{A_\theta B_\theta \cot \theta}{r} \right) \hat{\boldsymbol{\phi}}. \quad (4) \end{aligned}$$

see also CONVECTIVE ACCELERATION, CONVECTIVE DERIVATIVE, CURVILINEAR COORDINATES, GRADIENT

### Convergence Acceleration

see CONVERGENCE IMPROVEMENT

### Convergence Improvement

The improvement of the convergence properties of a SERIES, also called CONVERGENCE ACCELERATION, such that a SERIES reaches its limit to within some accuracy with fewer terms than required before. Convergence improvement can be effected by forming a linear combination with a SERIES whose sum is known. Useful sums include

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)} = 1 \quad (1)$$

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)(n+2)} = \frac{1}{4} \quad (2)$$

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)(n+2)(n+3)} = \frac{1}{18} \quad (3)$$

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1) \cdots (n+p)} = \frac{1}{p \cdot p!}. \quad (4)$$

Kummer's transformation takes a convergent series

$$s = \sum_{k=0}^{\infty} a_k \quad (5)$$

and another convergent series

$$c = \sum_{k=0}^{\infty} c_k \quad (6)$$

with known  $c$  such that

$$\lim_{k \rightarrow \infty} \frac{a_k}{c_k} = \lambda \neq 0. \quad (7)$$

Then a series with more rapid convergence to the same value is given by

$$s = \lambda c + \sum_{k=0}^{\infty} \left( 1 - \lambda \frac{c_k}{a_k} \right) a_k \quad (8)$$

(Abramowitz and Stegun 1972).

EULER'S TRANSFORM takes a convergent alternating series

$$\sum_{k=0}^{\infty} (-1)^k a_k = a_0 - a_1 + a_2 - \dots \quad (9)$$

into a series with more rapid convergence to the same value to

$$s = \sum_{k=0}^{\infty} \frac{(-1)^k \Delta^k a_0}{2^{k+1}}, \quad (10)$$

where

$$\Delta^k a_0 = \sum_{m=0}^k (-1)^m \binom{k}{m} a_{k-m} \quad (11)$$

(Abramowitz and Stegun 1972; Beeler *et al.* 1972, Item 120).

Given a series of the form

$$S = \sum_{n=1}^{\infty} f\left(\frac{1}{n}\right), \quad (12)$$

where  $f(z)$  is an ANALYTIC at 0 and on the closed unit DISK, and

$$f(z)|_{z \rightarrow 0} = \mathcal{O}(z^2), \quad (13)$$

then the series can be rearranged to

$$\begin{aligned} S &= \sum_{n=1}^{\infty} \sum_{m=2}^{\infty} f_m \left( \frac{1}{n} \right)^m \\ &= \sum_{m=2}^{\infty} \sum_{n=1}^{\infty} f_m \left( \frac{1}{n} \right)^m = \sum_{m=2}^{\infty} f_m \zeta(m), \quad (14) \end{aligned}$$

where

$$f(z) = \sum_{m=2}^{\infty} f_m z^m \quad (15)$$

is the MACLAURIN SERIES of  $f$  and  $\zeta(z)$  is the RIEMANN ZETA FUNCTION (Flajolet and Vardi 1996). The transformed series exhibits geometric convergence. Similarly, if  $f(z)$  is ANALYTIC in  $|z| \leq 1/n_0$  for some POSITIVE INTEGER  $n_0$ , then

$$S = \sum_{n=1}^{n_0-1} f\left(\frac{1}{n}\right) + \sum_{m=2}^{\infty} f_m \left[ \zeta(m) - \frac{1}{1^m} - \dots - \frac{1}{(n_0-1)^m} \right], \quad (16)$$

which converges geometrically (Flajolet and Vardi 1996). (16) can also be used to further accelerate the convergence of series (14).

### Convergent

The RATIONAL NUMBER obtained by keeping only a limited number of terms in a CONTINUED FRACTION is called a convergent. For example, in the SIMPLE CONTINUED FRACTION for the GOLDEN RATIO,

$$\phi = 1 + \frac{1}{1 + \frac{1}{1 + \dots}}$$

the convergents are

$$1, 1 + \frac{1}{1} = \frac{3}{2}, 1 + \frac{1}{1 + \frac{1}{1}} = \frac{5}{3}, \dots$$

The word convergent is also used to describe a CONVERGENT SEQUENCE or CONVERGENT SERIES.

see also CONTINUED FRACTION, CONVERGENT SEQUENCE, CONVERGENT SERIES, PARTIAL QUOTIENT, SIMPLE CONTINUED FRACTION

### Convergent Sequence

A SEQUENCE  $S_n$  converges to the limit  $S$

$$\lim_{n \rightarrow \infty} S_n = S$$

if, for any  $\epsilon > 0$ , there exists an  $N$  such that  $|S_n - S| < \epsilon$  for  $n > N$ . If  $S_n$  does not converge, it is said to DIVERGE. Every bounded MONOTONIC SEQUENCE converges. Every unbounded SEQUENCE diverges. This condition can also be written as

$$\overline{\lim}_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} S_n = S.$$

see also CONDITIONAL CONVERGENCE, STRONG CONVERGENCE, WEAK CONVERGENCE

### Convergent Series

The infinite SERIES  $\sum_{n=1}^{\infty} a_n$  is convergent if the SEQUENCE of partial sums

$$S_n = \sum_{k=1}^n a_k$$

is convergent. Conversely, a SERIES is divergent if the SEQUENCE of partial sums is divergent. If  $\sum u_k$  and  $\sum v_k$  are convergent SERIES, then  $\sum(u_k + v_k)$  and  $\sum(u_k - v_k)$  are convergent. If  $c \neq 0$ , then  $\sum u_k$  and  $c \sum u_k$  both converge or both diverge. Convergence and divergence are unaffected by deleting a finite number of terms from the beginning of a series. Constant terms in the denominator of a sequence can usually be deleted without affecting convergence. All but the highest POWER terms in POLYNOMIALS can usually be deleted in both NUMERATOR and DENOMINATOR of a SERIES without affecting convergence. If a SERIES converges absolutely, then it converges.

**Conversion Period**

The period of time between INTEREST payments.

see also COMPOUND INTEREST, INTEREST, SIMPLE INTEREST

**Convex**

A SET in EUCLIDEAN SPACE  $\mathbb{R}^d$  is convex if it contains *all* the LINE SEGMENTS connecting any pair of its points. If the SET does not contain all the LINE SEGMENTS, it is called CONCAVE.

see also CONNECTED SET, CONVEX FUNCTION, CONVEX HULL, CONVEX OPTIMIZATION THEORY, CONVEX POLYGON, DELAUNAY TRIANGULATION, MINKOWSKI CONVEX BODY THEOREM, SIMPLY CONNECTED

**References**

Croft, H. T.; Falconer, K. J.; and Guy, R. K. "Convexity." Ch. A in *Unsolved Problems in Geometry*. New York: Springer-Verlag, pp. 6–47, 1994.

**Convex Function**

A function whose value at the MIDPOINT of every INTERVAL in its DOMAIN does not exceed the AVERAGE of its values at the ends of the INTERVAL. In other words, a function  $f(x)$  is convex on an INTERVAL  $[a, b]$  if for any two points  $x_1$  and  $x_2$  in  $[a, b]$ ,

$$f\left[\frac{1}{2}(x_1 + x_2)\right] \leq \frac{1}{2}[f(x_1) + f(x_2)].$$

If  $f(x)$  has a second DERIVATIVE in  $[a, b]$ , then a NECESSARY and SUFFICIENT condition for it to be convex on that INTERVAL is that the second DERIVATIVE  $f''(x) > 0$  for all  $x$  in  $[a, b]$ .

**Convex Hull**

The convex hull of a set of points  $S$  is the INTERSECTION of all convex sets containing  $S$ . For  $N$  points  $p_1, \dots, p_N$ , the convex hull  $C$  is then given by the expression

$$C \equiv \left\{ \sum_{j=1}^N \lambda_j p_j : \lambda_j \geq 0 \text{ for all } j \text{ and } \sum_{j=1}^N \lambda_j = 1 \right\}.$$

**References**

Santaló, L. A. *Integral Geometry and Geometric Probability*. Reading, MA: Addison-Wesley, 1976.

**Convex Optimization Theory**

The problem of maximizing a linear function over a convex polyhedron, also known as OPERATIONS RESEARCH or OPTIMIZATION THEORY. The general problem of convex optimization is to find the minimum of a convex (or quasiconvex) function  $f$  on a FINITE-dimensional convex body  $A$ . Methods of solution include Levin's algorithm and the method of circumscribed ELLIPSOIDS, also called the Nemirovsky-Yudin-Shor method.

**References**

Tokhomirov, V. M. "The Evolution of Methods of Convex Optimization." *Amer. Math. Monthly* **103**, 65–71, 1996.

**Convex Polygon**

A POLYGON is CONVEX if it contains *all* the LINE SEGMENTS connecting any pair of its points. Let  $f(n)$  be the smallest number such that when  $W$  is a set of more than  $f(n)$  points in GENERAL POSITION (with no three points COLLINEAR) in the plane, all of the VERTICES of some convex  $n$ -gon are contained in  $W$ . The answers for  $n = 2, 3$ , and  $4$  are 2, 4, and 8. It is conjectured that  $f(n) = 2^{n-2}$ , but only proven that

$$2^{n-2} \leq f(n) \leq \binom{2n-4}{n-2},$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT.

**Convex Polyhedron**

A POLYHEDRON for which a line connecting any two (noncoplanar) points on the surface always lies in the interior of the polyhedron. The 92 convex polyhedra having only REGULAR POLYGONS as faces are called the JOHNSON SOLIDS, which include the PLATONIC SOLIDS and ARCHIMEDEAN SOLIDS. No method is known for computing the VOLUME of a general convex polyhedron (Ogilvy 1990, p. 173).

see also ARCHIMEDEAN SOLID, DELTAHEDRON, JOHNSON SOLID, KEPLER-POINOT SOLID, PLATONIC SOLID, REGULAR POLYGON

Ogilvy, C. S. *Excursions in Geometry*. New York: Dover, 1990.

### Convolution

A convolution is an integral which expresses the amount of overlap of one function  $g(t)$  as it is shifted over another function  $f(t)$ . It therefore “blends” one function with another. For example, in synthesis imaging, the measured DIRTY MAP is a convolution of the “true” CLEAN MAP with the DIRTY BEAM (the FOURIER TRANSFORM of the sampling distribution). The convolution is sometimes also known by its German name, FALTUNG (“folding”). A convolution over a finite range  $[0, t]$  is given by

$$f(t) * g(t) \equiv \int_0^t f(\tau)g(t-\tau) d\tau, \quad (1)$$

where the symbol  $f * g$  (occasionally also written as  $f \otimes g$ ) denotes convolution of  $f$  and  $g$ . Convolution is more often taken over an infinite range,

$$f(t) * g(t) \equiv \int_{-\infty}^{\infty} f(\tau)g(t-\tau) d\tau = \int_{-\infty}^{\infty} g(\tau)f(t-\tau) d\tau. \quad (2)$$

Let  $f$ ,  $g$ , and  $h$  be arbitrary functions and  $a$  a constant. Convolution has the following properties:

$$f * g = g * f \quad (3)$$

$$f * (g * h) = (f * g) * h \quad (4)$$

$$f * (g + h) = (f * g) + (f * h) \quad (5)$$

$$a(f * g) = (af) * g = f * (ag). \quad (6)$$

The INTEGRAL identity

$$\int_a^x \int_a^x f(t) dt dx = \int_a^x (x-t)f(t) dt \quad (7)$$

also gives a convolution. Taking the DERIVATIVE of a convolution gives

$$\frac{d}{dx}(f * g) = \frac{df}{dx} * g = f * \frac{dg}{dx}. \quad (8)$$

The AREA under a convolution is the product of areas under the factors,

$$\begin{aligned} \int_{-\infty}^{\infty} (f * g) dx &= \int_{-\infty}^{\infty} \left[ \int_{-\infty}^{\infty} f(u)g(x-u) du \right] dx \\ &= \int_{-\infty}^{\infty} f(u) \left[ \int_{-\infty}^{\infty} g(x-u) dx \right] du \\ &= \left[ \int_{-\infty}^{\infty} f(u) du \right] \left[ \int_{-\infty}^{\infty} g(x) dx \right]. \quad (9) \end{aligned}$$

The horizontal CENTROIDS add

$$\int_{-\infty}^{\infty} \langle x(f * g) \rangle dx = \langle xf \rangle + \langle xg \rangle, \quad (10)$$

as do the VARIANCES

$$\int_{-\infty}^{\infty} \langle x^2(f * g) \rangle dx = \langle x^2 f \rangle + \langle x^2 g \rangle, \quad (11)$$

where

$$\langle x^n f \rangle \equiv \frac{\int_{-\infty}^{\infty} x^n f(x) dx}{\int_{-\infty}^{\infty} f(x) dx}. \quad (12)$$

see also AUTOCORRELATION, CONVOLUTION THEOREM, CROSS-CORRELATION, WIENER-KHINTCHINE THEOREM

### Convolution Theorem

Let  $f(t)$  and  $f(t)$  be arbitrary functions of time  $t$  with FOURIER TRANSFORMS. Take

$$f(t) = \mathcal{F}^{-1}[F(\nu)] = \int_{-\infty}^{\infty} F(\nu)e^{2\pi i \nu t} d\nu \quad (1)$$

$$g(t) = \mathcal{F}^{-1}[G(\nu)] = \int_{-\infty}^{\infty} G(\nu)e^{2\pi i \nu t} d\nu, \quad (2)$$

where  $\mathcal{F}^{-1}$  denotes the inverse FOURIER TRANSFORM (where the transform pair is defined to have constants  $A = 1$  and  $B = -2\pi$ ). Then the CONVOLUTION is

$$\begin{aligned} f * g &\equiv \int_{-\infty}^{\infty} g(t')f(t-t')dt' \\ &= \int_{-\infty}^{\infty} g(t') \left[ \int_{-\infty}^{\infty} F(\nu)e^{2\pi i \nu(t-t')} d\nu \right] dt'. \quad (3) \end{aligned}$$

Interchange the order of integration,

$$\begin{aligned} f * g &= \int_{-\infty}^{\infty} F(\nu) \left[ \int_{-\infty}^{\infty} g(t')e^{-2\pi i \nu t'} dt' \right] e^{2\pi i \nu t} d\nu \\ &= \int_{-\infty}^{\infty} F(\nu)G(\nu)e^{2\pi i \nu t} d\nu \\ &= \mathcal{F}^{-1}[F(\nu)G(\nu)]. \quad (4) \end{aligned}$$

So, applying a FOURIER TRANSFORM to each side, we have

$$\mathcal{F}[f * g] = \mathcal{F}[f]\mathcal{F}[g]. \quad (5)$$

The convolution theorem also takes the alternate forms

$$\mathcal{F}[fg] = \mathcal{F}[f] * \mathcal{F}[g] \quad (6)$$

$$\mathcal{F}(\mathcal{F}[f]\mathcal{F}[g]) = f * g \quad (7)$$

$$\mathcal{F}(\mathcal{F}[f] * \mathcal{F}[g]) = fg. \quad (8)$$

### Conway's Game of Life

see LIFE

### Conway Groups

The AUTOMORPHISM GROUP  $Co_1$  of the LEECH LATTICE modulo a center of order two is called "the" Conway group. There are 15 exceptional CONJUGACY CLASSES of the Conway group. This group, combined with the GROUPS  $Co_2$  and  $Co_3$  obtained similarly from the LEECH LATTICE by stabilization of the 1-D and 2-D sublattices, are collectively called Conway groups. The Conway groups are SPORADIC GROUPS.

### Conway's Knot

The KNOT with BRAID WORD

$$\sigma_2^3 \sigma_1 \sigma_3^{-1} \sigma_2^{-2} \sigma_1 \sigma_2^{-1} \sigma_1 \sigma_3^{-1}.$$

The JONES POLYNOMIAL of Conway's knot is

$$t^{-4}(-1 + 2t - 2t^2 + 2t^3 + t^6 - 2t^7 + 2t^8 - 2t^9 + t^{10}),$$

the same as for the KINOSHITA-TERASAKA KNOT.

### Conway's Knot Notation

A concise NOTATION based on the concept of the TANGLE used by Conway (1967) to enumerate KNOTS up to 11 crossings. An ALGEBRAIC KNOT containing no NEGATIVE signs in its Conway knot NOTATION is an ALTERNATING KNOT.

see LIFE

### Conway Notation

see CONWAY'S KNOT NOTATION, CONWAY POLYHEDRON NOTATION

## Conway Polyhedron Notation

A NOTATION for POLYHEDRA which begins by specifying a “seed” polyhedron using a capital letter. The PLATONIC SOLIDS are denoted T (TETRAHEDRON), O (OCTAHEDRON), C (CUBE), I (ICOSAHEDRON), and D (DODECAHEDRON), according to their first letter. Other polyhedra include the PRISMS,  $P_n$ , ANTIPRISMS,  $A_n$ , and PYRAMIDS,  $Y_n$ , where  $n \geq 3$  specifies the number of sides of the polyhedron’s base.

Operations to be performed on the polyhedron are then specified with lower-case letters preceding the capital letter.

## Coordination Number

see KISSING NUMBER

## Copeland-Erdős Constant

The decimal 0.23571113171923... (Sloane’s A033308) obtained by concatenating the PRIMES: 2, 23, 235, 2357, 235711, ... (Sloane’s A033308; one of the SMARNDACHE SEQUENCES). In 1945, Copeland and Erdős showed that it is a NORMAL NUMBER. The first few digits of the CONTINUED FRACTION of the Copeland-Erdős are 0, 4, 4, 8, 16, 18, 5, 1, ... (Sloane’s A030168). The positions of the first occurrence of  $n$  in the CONTINUED FRACTION are 8, 16, 20, 2, 7, 15, 12, 4, 17, 254, ... (Sloane’s A033309). The incrementally largest terms are 1, 27, 154, 1601, 2135, ... (Sloane’s A033310), which occur at positions 2, 5, 11, 19, 1801, ... (Sloane’s A033311).

see RELATIVELY PRIME

### Copson-de Bruijn Constant

see DE BRUIJN CONSTANT

### Copson's Inequality

Let  $\{a_n\}$  be a NONNEGATIVE SEQUENCE and  $f(x)$  a NONNEGATIVE integrable function. Define

$$A_n = \sum_{k=1}^n a_k \quad (1)$$

$$B_n = \sum_{k=n}^{\infty} a_k \quad (2)$$

and

$$F(x) = \int_0^x f(t) dt \quad (3)$$

$$G(x) = \int_x^{\infty} f(t) dt, \quad (4)$$

and take  $0 < p < 1$ . For integrals,

$$\int_0^{\infty} \left[ \frac{G(x)}{x} \right]^p dx > \left( \frac{p}{p-1} \right)^p \int_0^{\infty} [f(x)]^p dx \quad (5)$$

(unless  $f$  is identically 0). For sums,

$$\left( 1 + \frac{1}{p-1} \right) B_1^p + \sum_{n=2}^{\infty} \left( \frac{B_n}{n} \right)^p > \left( \frac{p}{p-1} \right)^p \sum_{n=1}^{\infty} a_n^p \quad (6)$$

(unless all  $a_n = 0$ ).

### Copula

A function that joins univariate distribution functions to form multivariate distribution functions. A 2-D copula is a function  $C: I^2 \rightarrow I$  such that

$$C(0, t) = C(t, 0) = 0$$

and

$$C(1, t) = C(t, 1) = t$$

for all  $t \in I$ , and

$$C(u_2, v_2) - C(u_1, v_2) - C(u_2, v_1) + C(u_1, v_1) \geq 0$$

for all  $u_1, u_2, v_1, v_2 \in I$  such that  $u_1 \leq u_2$  and  $v_1 \leq v_2$ .

see also SKLAR'S THEOREM

### Cork Plug

A 3-D SOLID which can stopper a SQUARE, TRIANGULAR, or CIRCULAR HOLE. There is an infinite family of such shapes. The one with smallest VOLUME has TRIANGULAR CROSS-SECTIONS and  $V = \pi r^3$ ; that with the largest VOLUME is made using two cuts from the top diameter to the EDGE and has VOLUME  $V = 4\pi r^3/3$ .

see also STEREOLOGY, TRIP-LET

### Corkscrew Surface

A surface also called the TWISTED SPHERE.

#### Cornu Spiral

A plot in the COMPLEX PLANE of the points

$$B(z) = C(t) + iS(t) = \int_0^t e^{i\pi x^2/2} dx, \quad (1)$$

where  $C(z)$  and  $S(z)$  are the FRESNEL INTEGRALS. The Cornu spiral is also known as the CLOTHOID or EULER'S SPIRAL. A Cornu spiral describes diffraction from the edge of a half-plane.

The SLOPE of the Cornu spiral

$$m(t) = \frac{S(t)}{C(t)} \quad (2)$$

is plotted above.

The SLOPE of the curve's TANGENT VECTOR (above right figure) is

$$m_T(t) = \frac{S'(t)}{C'(t)} = \tan(\frac{1}{2}\pi t^2), \quad (3)$$

plotted below.

The CESÀRO EQUATION for a Cornu spiral is  $\rho = c^2/s$ , where  $\rho$  is the RADIUS OF CURVATURE and  $s$  the ARC LENGTH. The TORSION is  $\tau = 0$ .

Gray (1993) defines a generalization of the Cornu spiral given by parametric equations

$$x(t) = a \int_0^t \sin\left(\frac{u^{n+1}}{n+1}\right) du \quad (4)$$

$$y(t) = a \int_0^t \cos\left(\frac{u^{n+1}}{n+1}\right) du. \quad (5)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE of this curve are

$$s(t) = at \quad (3)$$

$$\kappa(t) = -\frac{t^n}{a} \quad (4)$$

$$\phi(t) = -\frac{t^{n+1}}{n+1}. \quad (5)$$

The CESÀRO EQUATION is

$$\kappa = -\frac{a}{s^n}. \quad (6)$$

Dillen (1990) describes a class of “polynomial spirals” for which the CURVATURE is a polynomial function of the ARC LENGTH. These spirals are a further generalization of the Cornu spiral.

### Correlation

see AUTOCORRELATION, CORRELATION COEFFICIENT, CORRELATION (GEOMETRIC), CORRELATION (STATISTICAL), CROSS-CORRELATION

### Correlation Coefficient

The correlation coefficient is a quantity which gives the quality of a LEAST SQUARES FITTING to the original data. To define the correlation coefficient, first consider the sum of squared values  $ss_{xx}$ ,  $ss_{xy}$ , and  $ss_{yy}$  of a set of  $n$  data points  $(x_i, y_i)$  about their respective means,

$$\begin{aligned} ss_{xx} &\equiv \Sigma(x_i - \bar{x})^2 = \Sigma x^2 - 2\bar{x}\Sigma x + \Sigma \bar{x}^2 \\ &= \Sigma x^2 - 2n\bar{x}^2 + n\bar{x}^2 = \Sigma x^2 - n\bar{x}^2 \end{aligned} \quad (1)$$

$$\begin{aligned} ss_{yy} &\equiv \Sigma(y_i - \bar{y})^2 = \Sigma y^2 - 2\bar{y}\Sigma y + \Sigma \bar{y}^2 \\ &= \Sigma y^2 - 2n\bar{y}^2 + n\bar{y}^2 = \Sigma y^2 - n\bar{y}^2 \end{aligned} \quad (2)$$

$$\begin{aligned} ss_{xy} &\equiv \Sigma(x_i - \bar{x})(y_i - \bar{y}) = \Sigma(x_i y_i - \bar{x} y_i - x_i \bar{y} + \bar{x} \bar{y}) \\ &= \Sigma x y - n\bar{x}\bar{y} - n\bar{x}\bar{y} + n\bar{x}\bar{y} = \Sigma x y - n\bar{x}\bar{y}. \end{aligned} \quad (3)$$

For linear LEAST SQUARES FITTING, the COEFFICIENT  $b$  in

$$y = a + bx \quad (4)$$

is given by

$$b = \frac{n \sum xy - \sum x \sum y}{n \sum x^2 - (\sum x)^2} = \frac{ss_{xy}}{ss_{xx}}, \quad (5)$$

and the COEFFICIENT  $b'$  in

$$x = a' + b'y \quad (6)$$

is given by

$$b' = \frac{n \sum xy - \sum x \sum y}{n \sum y^2 - (\sum y)^2}. \quad (7)$$

The correlation coefficient  $r^2$  (sometimes also denoted  $R^2$ ) is then defined by

$$r \equiv \sqrt{bb'} = \frac{n \sum xy - \sum x \sum y}{\sqrt{[n \sum x^2 - (\sum x)^2][n \sum y^2 - (\sum y)^2]}}, \quad (8)$$

which can be written more simply as

$$r^2 = \frac{SS_{xy}^2}{SS_{xx}SS_{yy}}. \quad (9)$$

The correlation coefficient is also known as the PRODUCT-MOMENT COEFFICIENT OF CORRELATION or PEARSON'S CORRELATION. The correlation coefficients for linear fits to increasingly noisy data are shown above.

The correlation coefficient has an important physical interpretation. To see this, define

$$A \equiv (\sum x^2 - n\bar{x}^2)^{-1} \quad (10)$$

and denote the "expected" value for  $y_i$  as  $\hat{y}_i$ . Sums of  $\hat{y}_i$  are then

$$\begin{aligned} \hat{y}_i &= a + bx_i = \bar{y} - b\bar{x} + bx_i = \bar{x} + b(x_i - \bar{x}) \\ &= A(\bar{y}\sum x^2 - \bar{x}\sum xy + x_i\sum xy - n\bar{x}\bar{y}x_i) \\ &= A[\bar{y}\sum x^2 + (x_i - \bar{x})\sum xy - n\bar{x}\bar{y}x_i] \end{aligned} \quad (11)$$

$$\sum \hat{y}_i = A(n\bar{y}\sum x^2 - n^2\bar{x}^2\bar{y}) \quad (12)$$

$$\begin{aligned} \sum \hat{y}_i^2 &= A^2[n\bar{y}^2(\sum x^2)^2 - n^2\bar{x}^2\bar{y}^2(\sum x^2) \\ &\quad - 2n\bar{x}\bar{y}(\sum xy)(\sum x^2) + 2n^2\bar{x}^3\bar{y}(\sum xy) \\ &\quad + (\sum x^2)(\sum xy)^2 - n\bar{x}^2(\sum xy)] \end{aligned} \quad (13)$$

$$\begin{aligned} \sum y_i \hat{y}_i &= A\sum[y_i\bar{y}\sum x^2 + y_i(x_i - \bar{x})\sum xy - n\bar{x}\bar{y}x_i y_i] \\ &= A[n\bar{y}^2\sum x^2 + (\sum xy)^2 - n\bar{x}\bar{y}\sum xy - n\bar{x}\bar{y}(\sum xy)] \\ &= A[n\bar{y}^2\sum x^2 + (\sum xy)^2 - 2n\bar{x}\bar{y}\sum xy]. \end{aligned} \quad (14)$$

The sum of squared residuals is then

$$\begin{aligned} SSR &\equiv \sum (\hat{y}_i - \bar{y})^2 = \sum (\hat{y}_i^2 - 2\bar{y}\hat{y}_i + \bar{y}^2) \\ &= A^2(\sum xy - n\bar{x}\bar{y})^2(\sum x^2 - n\bar{x}^2) = \frac{(\sum xy - n\bar{x}\bar{y})^2}{\sum x^2 - n\bar{x}^2} \\ &= bSS_{xy} = \frac{SS_{xy}^2}{SS_{xx}} = SS_{yy}r^2 = b^2SS_{xx}, \end{aligned} \quad (15)$$

and the sum of squared errors is

$$\begin{aligned} SSE &\equiv \sum (y_i - \hat{y}_i)^2 = \sum (y_i - \bar{y} + b\bar{x} - bx_i)^2 \\ &= \sum [y_i - \bar{y} - b(x_i - \bar{x})]^2 \\ &= \sum (y_i - \bar{y})^2 + b^2\sum (x_i - \bar{x})^2 - 2b\sum (x_i - \bar{x})(y_i - \bar{y}) \\ &= SS_{yy} + b^2SS_{xx} - 2bSS_{xy}. \end{aligned} \quad (16)$$

But

$$b = \frac{SS_{xy}}{SS_{xx}} \quad (17)$$

$$r^2 = \frac{SS_{xy}^2}{SS_{xx}SS_{yy}}, \quad (18)$$

so

$$\begin{aligned} SSE &= SS_{yy} + \frac{SS_{xy}^2}{SS_{xx}^2}SS_{xx} - 2\frac{SS_{xy}}{SS_{xx}}SS_{xy} \\ &= SS_{yy} - \frac{SS_{xy}^2}{SS_{xx}} \end{aligned} \quad (19)$$

$$\begin{aligned} &= SS_{yy} \left(1 - \frac{SS_{xy}^2}{SS_{xx}^2}\right) = SS_{yy}(1 - r^2) \\ &= s_y^2 - s_{\hat{y}}^2, \end{aligned} \quad (20)$$

and

$$SSE + SSR = SS_{yy}(1 - r^2) + SS_{yy}r^2 = SS_{yy}. \quad (21)$$

The square of the correlation coefficient  $r^2$  is therefore given by

$$r^2 \equiv \frac{SSR}{SS_{yy}} = \frac{SS_{xy}^2}{SS_{xx}SS_{yy}} = \frac{(\sum xy - n\bar{x}\bar{y})^2}{(\sum x^2 - n\bar{x}^2)(\sum y^2 - n\bar{y}^2)}. \quad (22)$$

In other words,  $r^2$  is the proportion of  $SS_{yy}$  which is accounted for by the regression.

If there is complete correlation, then the lines obtained by solving for best-fit  $(a, b)$  and  $(a', b')$  coincide (since all data points lie on them), so solving (6) for  $y$  and equating to (4) gives

$$y = -\frac{a'}{b'} + \frac{x}{b'} = a + bx. \quad (23)$$

Therefore,  $a = -a'/b'$  and  $b = 1/b'$ , giving

$$r^2 = bb' = 1. \quad (24)$$

The correlation coefficient is independent of both origin and scale, so

$$r(u, v) = r(x, y), \quad (25)$$

where

$$u \equiv \frac{x - x_0}{h} \quad (26)$$

$$v \equiv \frac{y - y_0}{h}. \quad (27)$$

### Correlation Coefficient—Gaussian Bivariate Distribution

For a GAUSSIAN BIVARIATE DISTRIBUTION, the distribution of correlation COEFFICIENTS is given by

$$\begin{aligned}
 P(r) &= \frac{1}{\pi} (N-2) (1-r^2)^{(N-4)/2} (1-\rho^2)^{(N-1)/2} \\
 &\quad \times \int_0^\infty \frac{d\beta}{(\cosh \beta - \rho r)^{N-1}} \\
 &= \frac{1}{\pi} (N-2) (1-r^2)^{(N-4)/2} (1-\rho^2)^{(N-1)/2} \sqrt{\frac{\pi}{2}} \frac{\Gamma(N-1)}{\Gamma(N-\frac{1}{2})} \\
 &\quad \times (1-\rho r)^{-(N-3/2)} {}_2F_1\left(\frac{1}{2}, \frac{1}{2}, \frac{2N-1}{2}, \frac{\rho r+1}{2}\right) \\
 &= \frac{(N-2)\Gamma(N-1)(1-\rho^2)^{(N-1)/2}(1-r^2)^{(N-4)/2}}{\sqrt{2\pi}\Gamma(N-\frac{1}{2})(1-\rho r)^{N-3/2}} \\
 &\quad \times \left[1 + \frac{1}{4} \frac{\rho r+1}{2N-1} + \frac{9}{16} \frac{(\rho r+1)^2}{(2N-1)(2N+1)} + \dots\right], \quad (1)
 \end{aligned}$$

where  $\rho$  is the population correlation COEFFICIENT,  ${}_2F_1(a, b; c; x)$  is a HYPERGEOMETRIC FUNCTION, and  $\Gamma(z)$  is the GAMMA FUNCTION (Kenney and Keeping 1951, pp. 217–221). The MOMENTS are

$$\langle r \rangle = \rho - \frac{\rho(1-\rho^2)}{2n} \quad (2)$$

$$\text{var}(r) = \frac{(1-\rho^2)^2}{n} \left(1 + \frac{11\rho^2}{2n} + \dots\right) \quad (3)$$

$$\gamma_1 = \frac{6\rho}{\sqrt{n}} \left(1 + \frac{77\rho^2 - 30}{12n} + \dots\right)$$

$$\gamma_2 = \frac{6}{n} (12\rho^2 - 1) + \dots, \quad (4)$$

where  $n \equiv N-1$ . If the variates are uncorrelated, then  $\rho = 0$  and

$$\begin{aligned}
 {}_2F_1\left(\frac{1}{2}, \frac{1}{2}, \frac{2N-1}{2}, \frac{\rho r+1}{2}\right) &= {}_2F_1\left(\frac{1}{2}, \frac{1}{2}, \frac{2N-1}{2}, \frac{1}{2}\right) \\
 &= \frac{\Gamma(N-\frac{1}{2})2^{3/2-N}\sqrt{\pi}}{[\Gamma(\frac{N}{2})]^2}, \quad (5)
 \end{aligned}$$

so

$$\begin{aligned}
 P(r) &= \frac{(N-2)\Gamma(N-1)}{\sqrt{2\pi}\Gamma(N-\frac{1}{2})} (1-r^2)^{(N-4)/2} \\
 &\quad \times \frac{\Gamma(N-\frac{1}{2})2^{3/2-N}\sqrt{\pi}}{[\Gamma(\frac{N}{2})]^2} \\
 &= \frac{2^{1-N}(N-2)\Gamma(N-1)}{[\Gamma(\frac{N}{2})]^2} (1-r^2)^{(N-4)/2}. \quad (6)
 \end{aligned}$$

But from the LEGENDRE DUPLICATION FORMULA,

$$\sqrt{\pi}\Gamma(N-1) = 2^{N-2}\Gamma(\frac{N}{2})\Gamma(\frac{N-1}{2}), \quad (7)$$

so

$$\begin{aligned}
 P(r) &= \frac{(2^{1-N})(2^{N-2})(N-2)\Gamma(\frac{N}{2})\Gamma(\frac{N-1}{2})}{\sqrt{\pi}[\Gamma(\frac{N}{2})]^2} (1-r^2)^{(N-4)/2} \\
 &= \frac{(N-2)\Gamma(\frac{N-1}{2})}{2\sqrt{\pi}\Gamma(\frac{N}{2})} (1-r^2)^{(N-4)/2} \\
 &= \frac{1}{\sqrt{\pi}} \frac{\frac{\nu}{2}\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2}+1)} (1-r^2)^{(\nu-2)/2} \\
 &= \frac{1}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} (1-r^2)^{(\nu-2)/2}. \quad (8)
 \end{aligned}$$

The uncorrelated case can be derived more simply by letting  $\beta$  be the true slope, so that  $\eta = \alpha + \beta x$ . Then

$$t \equiv (b-\beta) \frac{s_x}{s_y} \sqrt{\frac{N-2}{1-r^2}} = \frac{(b-\beta)r}{b} \sqrt{\frac{N-2}{1-r^2}} \quad (9)$$

is distributed as STUDENT'S  $t$  with  $\nu \equiv N-2$  DEGREES OF FREEDOM. Let the population regression COEFFICIENT  $\rho$  be 0, then  $\beta = 0$ , so

$$t = r \sqrt{\frac{\nu}{1-r^2}}, \quad (10)$$

and the distribution is

$$P(t) dt = \frac{1}{\sqrt{\nu\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2}) (1+\frac{t^2}{\nu})^{(\nu+1)/2}} dt. \quad (11)$$

Plugging in for  $t$  and using

$$\begin{aligned}
 dt &= \sqrt{\nu} \left[ \frac{\sqrt{1-r^2} - r(\frac{1}{2})(-2r)(1-r^2)^{-1/2}}{1-r^2} \right] dr \\
 &= \sqrt{\frac{\nu}{1-r^2}} \left( \frac{1-r^2+r^2}{1-r^2} \right) dr \\
 &= \sqrt{\frac{\nu}{(1-r)^3}} dr \quad (12)
 \end{aligned}$$

gives

$$\begin{aligned}
 P(t) dt &= \frac{1}{\sqrt{\nu\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2}) \left[1 + \frac{r^2\nu}{(1-r^2)\nu}\right]^{(\nu+1)/2}} \sqrt{\frac{\nu}{(1-r)^3}} dr \\
 &= \frac{(1-r^2)^{-3/2}}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2}) \left(\frac{1}{1-r^2}\right)^{(\nu+1)/2}} dr \\
 &= \frac{1}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} (1-r^2)^{-3/2} (1-r^2)^{(\nu+1)/2} dr \\
 &= \frac{1}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} (1-r^2)^{(\nu-2)/2} dr, \quad (13)
 \end{aligned}$$

so

$$P(r) = \frac{1}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} (1-r^2)^{(\nu-2)/2} \quad (14)$$

as before. See Bevington (1969, pp. 122–123) or Pugh and Winslow (1966, §12-8). If we are interested instead in the probability that a correlation COEFFICIENT would be obtained  $\geq |r|$ , where  $r$  is the observed COEFFICIENT, then

$$\begin{aligned}
 P_c(r, N) &= 2 \int_{|r|}^1 P(r', N) dr' = 1 - 2 \int_0^{|r|} P(r', N) dr' \\
 &= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} \int_0^{|r|} (1-r'^2)^{(\nu-2)/2} dr'. \quad (15)
 \end{aligned}$$

Let  $I \equiv \frac{1}{2}(\nu - 2)$ . For EVEN  $\nu$ , the exponent  $I$  is an INTEGER so, by the BINOMIAL THEOREM,

$$(1-r^2)^I = \sum_{k=0}^I \binom{I}{k} (-r^2)^k \quad (16)$$

and

$$\begin{aligned}
 P_c(r) &= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} (-1)^k \frac{I!}{(I-k)!k!} \int_0^{|r|} \sum_{k=0}^I r'^{2k} dr' \\
 &= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} \sum_{k=0}^I \left[ (-1)^k \frac{I!}{(I-k)!k!} \frac{|r|^{2k+1}}{2k+1} \right]. \quad (17)
 \end{aligned}$$

For ODD  $\nu$ , the integral is

$$\begin{aligned}
 P_c(r) &= 1 - 2 \int_0^{|r|} P(r') dr' \\
 &= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} \int_0^{|r|} (\sqrt{1-r'^2})^{\nu-2} dr'. \quad (18)
 \end{aligned}$$

Let  $r \equiv \sin x$  so  $dr = \cos x dx$ , then

$$\begin{aligned}
 P_c(r) &= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} \int_0^{\sin^{-1}|r|} \cos^{\nu-2} x \cos x dx \\
 &= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} + \int_0^{\sin^{-1}|r|} \cos^{\nu-1} x dx. \quad (19)
 \end{aligned}$$

But  $\nu$  is ODD, so  $\nu - 1 \equiv 2n$  is EVEN. Therefore

$$\begin{aligned}
 \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} &= \frac{2}{\sqrt{\pi}} \frac{\Gamma(n+1)}{\Gamma(n+\frac{1}{2})} = \frac{2}{\sqrt{\pi}} \frac{n!}{\frac{(2n-1)!!}{2^n} \sqrt{\pi}} \\
 &= \frac{2}{\pi} \frac{2^n n!}{(2n-1)!!} = \frac{2}{\pi} \frac{(2n)!!}{(2n-1)!!}. \quad (20)
 \end{aligned}$$

Combining with the result from the COSINE INTEGRAL gives

$$\begin{aligned}
 P_c(r) &= 1 - \frac{2}{\pi} \frac{(2n)!!(2n-1)!!}{(2n-1)!!(2n)!!} \\
 &\times \left[ \sin x \sum_{k=0}^{n-1} \frac{(2k)!!}{(2k+1)!!} \cos^{2k+1} x + x \right]_0^{\sin^{-1}|r|}. \quad (21)
 \end{aligned}$$

Use

$$\cos^{2k-1} x = (1-r^2)^{(2k-1)/2} = (1-r^2)^{(k-1/2)}, \quad (22)$$

and define  $J \equiv n - 1 = (\nu - 3)/2$ , then

$$\begin{aligned}
 P_c(r) &= 1 - \frac{2}{\pi} \left[ \sin^{-1}|r| + |r| \sum_{k=0}^J \frac{(2k)!!}{(2k+1)!!} (1-r^2)^{k+1/2} \right]. \quad (23)
 \end{aligned}$$

(In Bevington 1969, this is given incorrectly.) Combining the correct solutions

$$P_c(r) = \begin{cases} 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma[(\nu+1)/2]}{\Gamma(\nu/2)} \sum_{k=0}^I \left[ (-1)^k \frac{I!}{(I-k)!k!} \frac{|r|^{2k+1}}{2k+1} \right] & \text{for } \nu \text{ even} \\ 1 - \frac{2}{\pi} \left[ \sin^{-1}|r| + |r| \sum_{k=0}^J \frac{(2k)!!}{(2k+1)!!} (1-r^2)^{k+1/2} \right] & \text{for } \nu \text{ odd} \end{cases} \quad (24)$$

If  $\rho \neq 0$ , a skew distribution is obtained, but the variable  $z$  defined by

$$z \equiv \tanh^{-1} r \quad (25)$$

is approximately normal with

$$\mu_z = \tanh^{-1} \rho \quad (26)$$

$$\sigma_z^2 = \frac{1}{N-3} \quad (27)$$

(Kenney and Keeping 1962, p. 266).

Let  $b_j$  be the slope of a best-fit line, then the multiple correlation COEFFICIENT is

$$R^2 = \sum_{j=1}^n \left( b_j \frac{s_{jy}^2}{s_y^2} \right) = \sum_{j=1}^n \left( b_j \frac{s_j}{s_y} r_{jy} \right), \quad (28)$$

where  $s_{jy}$  is the sample VARIANCE.

On the surface of a SPHERE,

$$r \equiv \frac{\int f g d\Omega}{\int f d\Omega \int g d\Omega}, \quad (29)$$

where  $d\Omega$  is a differential SOLID ANGLE. This definition guarantees that  $-1 < r < 1$ . If  $f$  and  $g$  are expanded in REAL SPHERICAL HARMONICS,

$$f(\theta, \phi) \equiv \sum_{l=0}^{\infty} \sum_{m=0}^l [C_l^m Y_l^{m,c}(\theta, \phi) \sin(m\phi) + S_l^m Y_l^{m,s}(\theta, \phi)] \quad (30)$$

$$g(\theta, \phi) \equiv \sum_{l=0}^{\infty} \sum_{m=0}^l [A_l^m Y_l^{m,c}(\theta, \phi) \sin(m\phi) + B_l^m Y_l^{m,s}(\theta, \phi)]. \quad (31)$$

Then

$$r_l = \frac{\sum_{m=0}^l (C_l^m A_l^m + S_l^m B_l^m)}{\sqrt{\sum_{m=0}^l (C_l^{m^2} + S_l^{m^2})} \sqrt{\sum_{m=0}^l (A_l^{m^2} + B_l^{m^2})}}. \quad (32)$$

The confidence levels are then given by

$$\begin{aligned} G_1(r) &= r \\ G_2(r) &= r(1 + \frac{1}{2}s^2) = \frac{1}{2}r(3 - r^2) \\ G_3(r) &= r[1 + \frac{1}{2}s^2(1 + \frac{3}{4}s^2)] = \frac{1}{8}r(15 - 10r^2 + 3r^4) \\ G_4(r) &= r\{1 + \frac{1}{2}s^2[1 + \frac{3}{4}s^2(1 + \frac{5}{6}s^2)]\} \\ &= \frac{1}{16}r(35 - 35r^2 + 21r^4 - 5r^6), \end{aligned}$$

where

$$s \equiv \sqrt{1 - r^2} \quad (33)$$

(Eckhardt 1984).

### Correlation Dimension

Define the correlation integral as

$$C(\epsilon) \equiv \lim_{n \rightarrow \infty} \frac{1}{N^2} \sum_{\substack{i,j=1 \\ i \neq j}}^{\infty} H(\epsilon - ||x_i - x_j||), \quad (1)$$

where  $H$  is the HEAVISIDE STEP FUNCTION. When the below limit exists, the correlation dimension is then defined as

$$D_2 \equiv d_{\text{cor}} \equiv \lim_{\epsilon, \epsilon' \rightarrow 0^+} \frac{\ln \left[ \frac{C(\epsilon)}{C(\epsilon')} \right]}{\ln \left( \frac{\epsilon}{\epsilon'} \right)}. \quad (2)$$

If  $\nu$  is the CORRELATION EXPONENT, then

$$\lim_{\epsilon \rightarrow 0} \nu \rightarrow D_2. \quad (3)$$

It satisfies

$$d_{\text{cor}} \leq d_{\text{inf}} \leq d_{\text{cap}} \stackrel{?}{=} d_{\text{LYA}}. \quad (4)$$

To estimate the correlation dimension of an  $M$ -dimensional system with accuracy  $(1-Q)$  requires  $N_{\text{min}}$  data points, where

$$N_{\text{min}} \geq \left[ \frac{R(2-Q)}{2(1-Q)} \right]^M, \quad (5)$$

where  $R \geq 1$  is the length of the "plateau region." If an ATTRACTOR exists, then an estimate of  $D_2$  saturates above some  $M$  given by

$$M \geq 2D + 1, \quad (6)$$

which is sometimes known as the fractal Whitney embedding prevalence theorem.

### Correlation Exponent

A measure  $\nu$  of a STRANGE ATTRACTOR which allows the presence of CHAOS to be distinguished from random noise. It is related to the CAPACITY DIMENSION  $D$  and INFORMATION DIMENSION  $\sigma$ , satisfying

$$\nu \leq \sigma \leq D. \quad (1)$$

It satisfies

$$\nu \leq D_{\text{KY}}, \quad (2)$$

where  $D_{\text{KY}}$  is the KAPLAN-YORKE DIMENSION. As the cell size goes to zero,

$$\lim_{\epsilon \rightarrow 0} \nu \rightarrow D_2, \quad (3)$$

where  $D_2$  is the CORRELATION DIMENSION.

**Correlation (Geometric)**

A point-to-line and line-to-point TRANSFORMATION which transforms points  $A$  into lines  $a'$  and lines  $b$  into points  $B'$  such that  $a'$  passes through  $B'$  IFF  $A'$  lies on  $b$ .

see also POLARITY

**Correlation Index**

$$r_c \equiv \frac{s_y \hat{y}}{s_y s_{\hat{y}}} \\ r_c^2 = \frac{s_{\hat{y}}^2}{s_y^2} = 1 - \frac{\text{SSE}}{s_y^2}.$$

see also CORRELATION COEFFICIENT

**Correlation Integral**

Consider a set of points  $\mathbf{X}_i$  on an ATTRACTOR, then the correlation integral is

$$C(l) \equiv \lim_{N \rightarrow \infty} \frac{1}{N^2} f,$$

where  $f$  is the number of pairs  $(i, j)$  whose distance  $|\mathbf{X}_i - \mathbf{X}_j| < l$ . For small  $l$ ,

$$C(l) \sim l^\nu,$$

where  $\nu$  is the CORRELATION EXPONENT.

**References**

Grassberger, P. and Procaccia, I. "Measuring the Strangeness of Strange Attractors." *Physica D* 9, 189-208, 1983.

**Correlation Ratio**

Let there be  $N_i$  observations of the  $i$ th phenomenon, where  $i = 1, \dots, p$  and

$$N \equiv \sum N_i \quad (1)$$

$$\bar{y}_i \equiv \frac{1}{N_i} \sum_{\alpha} y_{i\alpha} \quad (2)$$

$$\bar{y} \equiv \frac{1}{N} \sum_i \sum_{\alpha} y_{i\alpha}. \quad (3)$$

Then

$$E_{y^2} \equiv \frac{\sum_i N_i (y_i - \bar{y})^2}{\sum_i \sum_{\alpha} (y_{i\alpha} - \bar{y})^2}. \quad (4)$$

Let  $\eta_{yx}$  be the population correlation ratio. If  $N_i = N_j$  for  $i \neq j$ , then

$$f(E^2) = \frac{e^{-\lambda} (E^2)^{a-1} (1 - E^2)^{b-1} {}_1F_1(a, b; \lambda E^2)}{B(a, b)}, \quad (5)$$

where

$$\lambda \equiv \frac{N\eta^2}{2(1 - \eta^2)} \quad (6)$$

$$a \equiv \frac{n_1}{2} \quad (7)$$

$$b \equiv \frac{n_2}{2}, \quad (8)$$

and  ${}_1F_1(a, b; z)$  is the CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION. If  $\lambda = 0$ , then

$$f(E^2) = \beta(a, b) \quad (9)$$

(Kenney and Keeping 1951, pp. 323-324).

see also CORRELATION COEFFICIENT, REGRESSION COEFFICIENT

**References**

Kenney, J. F. and Keeping, E. S. *Mathematics of Statistics*, Pt. 2, 2nd ed. Princeton, NJ: Van Nostrand, 1951.

**Correlation (Statistical)**

For two variables  $x$  and  $y$ ,

$$\text{cor}(x, y) \equiv \frac{\text{cov}(x, y)}{\sigma_x \sigma_y}, \quad (1)$$

where  $\sigma_x$  denotes STANDARD DEVIATION and  $\text{cov}(x, y)$  is the COVARIANCE of these two variables. For the general case of variables  $x_i$  and  $x_j$ , where  $i, j = 1, 2, \dots, n$ ,

$$\text{cor}(x_i, x_j) = \frac{\text{cov}(x_i, x_j)}{\sqrt{V_{ii} V_{jj}}}, \quad (2)$$

where  $V_{ii}$  are elements of the COVARIANCE MATRIX. In general, a correlation gives the strength of the relationship between variables. The variance of any quantity is always NONNEGATIVE by definition, so

$$\text{var} \left( \frac{x}{\sigma_x} + \frac{y}{\sigma_y} \right) \geq 0. \quad (3)$$

From a property of VARIANCES, the sum can be expanded

$$\text{var} \left( \frac{x}{\sigma_x} \right) + \text{var} \left( \frac{y}{\sigma_y} \right) + 2 \text{cov} \left( \frac{x}{\sigma_x}, \frac{y}{\sigma_y} \right) \geq 0 \quad (4)$$

$$\frac{1}{\sigma_x^2} \text{var}(x) + \frac{1}{\sigma_y^2} \text{var}(y) + \frac{2}{\sigma_x \sigma_y} \text{cov}(x, y) \geq 0 \quad (5)$$

$$1 + 1 + \frac{2}{\sigma_x \sigma_y} \text{cov}(x, y) = 2 + \frac{2}{\sigma_x \sigma_y} \text{cov}(x, y) \geq 0. \quad (6)$$

Therefore,

$$\text{cor}(x, y) = \frac{\text{cov}(x, y)}{\sigma_x \sigma_y} \geq -1. \quad (7)$$

Similarly,

$$\text{var}\left(\frac{x}{\sigma_x}\right) - \left(\frac{y}{\sigma_y}\right) \geq 0 \quad (8)$$

$$\text{var}\left(\frac{x}{\sigma_x}\right) + \text{var}\left(-\frac{y}{\sigma_y}\right) + 2\text{cov}\left(\frac{x}{\sigma_x}, -\frac{y}{\sigma_y}\right) \geq 0 \quad (9)$$

$$\frac{1}{\sigma_x^2} \text{var}(x) + \frac{1}{\sigma_y^2} \text{var}(y) - \frac{2}{\sigma_x \sigma_y} \text{cov}(x, y) \geq 0 \quad (10)$$

$$1 + 1 - \frac{2}{\sigma_x \sigma_y} \text{cov}(x, y) = 2 - \frac{2}{\sigma_x \sigma_y} \text{cov}(x, y) \geq 0. \quad (11)$$

Therefore,

$$\text{cor}(x, y) = \frac{\text{cov}(x, y)}{\sigma_x \sigma_y} \leq 1, \quad (12)$$

so  $-1 \leq \text{cor}(x, y) \leq 1$ . For a linear combination of two variables,

$$\begin{aligned} \text{var}(y - bx) &= \text{var}(y) + \text{var}(-bx) + 2\text{cov}(y, -bx) \\ &= \text{var}(y) + b^2 \text{var}(x) - 2b \text{cov}(x, y) \\ &= \sigma_y^2 + \sigma_x^2 - 2b \text{cov}(x, y). \end{aligned} \quad (13)$$

Examine the cases where  $\text{cor}(x, y) = \pm 1$ ,

$$\text{cor}(x, y) \equiv \frac{\text{cov}(x, y)}{\sigma_x \sigma_y} = \pm 1 \quad (14)$$

$$\text{var}(y - bx) = b^2 \sigma_x^2 + \sigma_y^2 \mp 2b \sigma_x \sigma_y = (b \sigma_x \mp \sigma_y)^2. \quad (15)$$

The VARIANCE will be zero if  $b \equiv \pm \sigma_y / \sigma_x$ , which requires that the argument of the VARIANCE is a constant. Therefore,  $y - bx = a$ , so  $y = a + bx$ . If  $\text{cor}(x, y) = \pm 1$ ,  $y$  is either perfectly correlated ( $b > 0$ ) or perfectly anti-correlated ( $b < 0$ ) with  $x$ .

see also COVARIANCE, COVARIANCE MATRIX, VARIANCE

### Cosecant

The function defined by  $\csc x \equiv 1/\sin x$ , where  $\sin x$  is the SINE. The MACLAURIN SERIES of the cosecant function is

$$\begin{aligned} \csc x &= \frac{1}{x} + \frac{1}{6}x + \frac{7}{360}x^3 + \frac{31}{15120}x^5 + \dots \\ &+ \frac{(-1)^{n+1} 2(2^{2n-1} - 1) B_{2n}}{(2n)!} x^{2n-1} + \dots, \end{aligned}$$

where  $B_{2n}$  is a BERNOULLI NUMBER.

see also INVERSE COSECANT, SECANT, SINE

Spanier, J. and Oldham, K. B. "The Secant  $\sec(x)$  and Cosecant  $\csc(x)$  Functions." Ch. 33 in *An Atlas of Functions*. Washington, DC: Hemisphere, pp. 311-318, 1987.

### Coset

Consider a countable SUBGROUP  $H$  with ELEMENTS  $h_i$  and an element  $x$  not in  $H$ , then

$$xh_i \quad (1)$$

$$h_i x \quad (2)$$

for  $i = 1, 2, \dots$  are left and right cosets of the SUBGROUP  $H$  with respect to  $x$ . The coset of a SUBGROUP has the same number of ELEMENTS as the SUBGROUP. The ORDER of any SUBGROUP is a divisor of the ORDER of the GROUP. The original GROUP can be represented by

$$G = H + x_1 H + x_2 H + \dots \quad (3)$$

For  $G$  a not necessarily FINITE GROUP with  $H$  a SUBGROUP of  $G$ , define an EQUIVALENCE RELATION  $x \sim y$  if  $x = hy$  for some  $h$  in  $H$ . Then the EQUIVALENCE CLASSES are the left (or right, depending on convention) cosets of  $H$  in  $G$ , namely the sets

$$\{x \in G : x = ha \text{ for some } h \text{ in } H\}, \quad (4)$$

where  $a$  is an element of  $G$ .

see also EQUIVALENCE CLASS, GROUP, SUBGROUP

### Cosh

see HYPERBOLIC COSINE

### Cosine

Let  $\theta$  be an ANGLE measured counterclockwise from the  $x$ -axis along the arc of the unit CIRCLE. Then  $\cos \theta$  is the horizontal coordinate of the arc endpoint. As a result of this definition, the cosine function is periodic with period  $2\pi$ .

The cosine function has a FIXED POINT at 0.739085.

The cosine function can be defined algebraically using the infinite sum

$$\cos x \equiv \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!} = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots, \quad (1)$$

or the INFINITE PRODUCT

$$\cos x = \prod_{n=1}^{\infty} \left[ 1 - \frac{4x^2}{\pi^2(2n-1)^2} \right]. \quad (2)$$

A close approximation to  $\cos(x)$  for  $x \in [0, \pi/2]$  is

$$\cos\left(\frac{\pi}{2}x\right) \approx 1 - \frac{x^2}{x + (1-x)\sqrt{\frac{2-x}{3}}} \quad (3)$$

(Hardy 1959). The difference between  $\cos x$  and Hardy's approximation is plotted below.

The FOURIER TRANSFORM of  $\cos(2\pi k_0 x)$  is given by

$$\begin{aligned} \mathcal{F}[\cos(2\pi k_0 x)] &= \int_{-\infty}^{\infty} e^{-2\pi i k x} \cos(2\pi k_0 x) dx \\ &= \frac{1}{2} [\delta(k - k_0) + \delta(k + k_0)], \end{aligned} \quad (4)$$

where  $\delta(k)$  is the DELTA FUNCTION.

The cosine sum rule gives an expansion of the COSINE function of a multiple ANGLE in terms of a sum of POWERS of sines and cosines,

$$\begin{aligned} \cos(n\theta) &= 2 \cos \theta \cos[(n-1)\theta] - \cos[(n-2)\theta] \\ &= \cos^n \theta - \binom{n}{2} \cos^{n-2} \theta \sin^2 \theta \\ &\quad + \binom{n}{4} \cos^{n-4} \theta \sin^4 \theta - \dots \end{aligned} \quad (5)$$

Summing the COSINE of a multiple angle from  $n = 0$  to  $N - 1$  can be done in closed form using

$$\sum_{n=0}^{N-1} \cos(nx) = \Re \left[ \sum_{n=0}^{N-1} e^{inx} \right]. \quad (6)$$

The EXPONENTIAL SUM FORMULAS give

$$\begin{aligned} \sum_{n=0}^{N-1} \cos(nx) &= \Re \left[ \frac{\sin(\frac{1}{2}Nx)}{\sin(\frac{1}{2}x)} e^{i(N-1)x/2} \right] \\ &= \frac{\sin(\frac{1}{2}Nx)}{\sin(\frac{1}{2}x)} \cos[\frac{1}{2}x(N-1)]. \end{aligned} \quad (7)$$

Similarly,

$$\sum_{n=0}^{\infty} p^n \cos(nx) = \Re \left[ \sum_{n=0}^{\infty} p^n e^{inx} \right], \quad (8)$$

where  $|p| < 1$ . The EXPONENTIAL SUM FORMULA gives

$$\begin{aligned} \sum_{n=0}^{\infty} p^n \cos(nx) &= \Re \left[ \frac{1 - pe^{-ix}}{1 - 2p \cos x + p^2} \right] \\ &= \frac{1 - p \cos x}{1 - 2p \cos x + p^2}. \end{aligned} \quad (9)$$

Cvijović and Klinowski (1995) note that the following series

$$C_\nu(\alpha) = \sum_{k=0}^{\infty} \frac{\cos(2k+1)\alpha}{(2k+1)^\nu} \quad (10)$$

has closed form for  $\nu = 2n$ ,

$$C_{2n}(\alpha) = \frac{(-1)^n}{4(2n-1)!} \pi^{2n} E_{2n-1}\left(\frac{\alpha}{\pi}\right), \quad (11)$$

where  $E_n(x)$  is an EULER POLYNOMIAL.

### Cosine Apodization Function

The APODIZATION FUNCTION

$$A(x) = \cos\left(\frac{\pi x}{2a}\right).$$

Its FULL WIDTH AT HALF MAXIMUM is  $4a/3$ . Its INSTRUMENT FUNCTION is

$$I(k) = \frac{4a \cos(2\pi ak)}{\pi(1 - 16a^2 k^2)}.$$

see also APODIZATION FUNCTION

### Cosine Circle

Also called the second LEMOINE CIRCLE. Draw lines through the LEMOINE POINT  $K$  and PARALLEL to the sides of the TRIANGLES. The points where the antiparallel lines intersect the sides then lie on a CIRCLE known as the cosine circle with center at  $K$ . The CHORDS  $P_2Q_3$ ,  $P_3Q_1$ , and  $P_1Q_2$  are proportional to the COSINES of the ANGLES of  $\Delta A_1A_2A_3$ , giving the circle its name.

TRIANGLES  $P_1P_2P_3$  and  $\Delta A_1A_2A_3$  are directly similar, and TRIANGLES  $\Delta Q_1Q_2Q_3$  and  $A_1A_2A_3$  are similar. The MIQUEL POINT of  $\Delta P_1P_2P_3$  is at the BROCARD POINT  $\Omega$  of  $\Delta P_1P_2P_3$ .

### Cosine Integral

There are (at least) three types of "cosine integrals," denoted  $\text{ci}(x)$ ,  $\text{Ci}(x)$ , and  $\text{Cin}(x)$ :

$$\text{ci}(x) \equiv - \int_x^\infty \frac{\cos t}{t} dt \quad (1)$$

$$= \frac{1}{2} [\text{ei}(ix) + \text{ei}(-ix)] \quad (2)$$

$$= -\frac{1}{2} [\text{E}_1(ix) + \text{E}_1(-ix)], \quad (3)$$

$$\text{Ci}(x) \equiv \gamma + \ln x + \int_0^x \frac{\cos t - 1}{t} dt \quad (4)$$

$$\text{Cin}(x) \equiv \int_0^x \frac{(1 - \cos t)}{t} dt \quad (5)$$

$$= -\text{Ci}(x) + \ln x + \gamma. \quad (6)$$

Here,  $\text{ei}(x)$  is the EXPONENTIAL INTEGRAL,  $\text{E}_n(x)$  is the  $\text{E}_n$ -FUNCTION, and  $\gamma$  is the EULER-MASCHERONI CONSTANT.  $\text{ci}(x)$  is the function returned by the *Mathematica*® (Wolfram Research, Champaign, IL) command `CosIntegral[x]` and displayed above.

To compute the integral of an EVEN power times a cosine,

$$I \equiv \int x^{2n} \cos(mx) dx, \quad (7)$$

use INTEGRATION BY PARTS. Let

$$u = x^{2n} \quad dv = \cos(mx) dx \quad (8)$$

$$du = 2nx^{2n-1} dx \quad v = \frac{1}{m} \sin(mx), \quad (9)$$

so

$$I = \frac{1}{m} x^{2n} \sin(mx) - \frac{2n}{m} \int x^{2n-1} \sin(mx) dx. \quad (10)$$

Using INTEGRATION BY PARTS again,

$$u = x^{2n-1} \quad dv = \sin(mx) dx \quad (11)$$

$$du = (2n-1)x^{2n-2} dx \quad v = -\frac{1}{m} \cos(mx), \quad (12)$$

and

$$\begin{aligned} \int x^{2n} \cos(mx) dx &= \frac{1}{m} x^{2n} \sin(mx) - \frac{2n}{m} \left[ -\frac{1}{m} x^{2n-1} \cos(mx) \right. \\ &\quad \left. + \frac{2n-1}{m} \int x^{2n-2} \cos(mx) dx \right] \\ &= \frac{1}{m} x^{2n} \sin(mx) + \frac{2n}{m^2} x^{2n-1} \cos(mx) \\ &\quad - \frac{(2n)(2n-1)}{m^2} \int x^{2n-2} \cos(mx) dx \\ &= \frac{1}{m} x^{2n} \sin(mx) + \frac{2n}{m^2} x^{2n-1} \cos(mx) \\ &\quad + \dots + \frac{(2n)!}{m^{2n}} \int x^0 \cos(mx) dx \\ &= \frac{1}{m} x^{2n} \sin(mx) + \frac{2n}{m^2} x^{2n-1} \cos(mx) \\ &\quad + \dots + \frac{(2n)!}{m^{2n+1}} \sin(mx) \\ &= \sin(mx) \sum_{k=0}^n (-1)^{k+1} \frac{(2n)!}{(2n-2k)! m^{2k+1}} x^{2n-2k} \\ &\quad + \cos(mx) \sum_{k=1}^n (-1)^{k+1} \frac{(2n)!}{(2k-2n-1)! m^{2k}} x^{2n-2k+1}. \end{aligned} \quad (13)$$

Letting  $k' \equiv n-k$ ,

$$\begin{aligned} \int x^{2n} \cos(mx) dx &= \sin(mx) \sum_{k=0}^n (-1)^{n-k+1} \frac{(2n)!}{(2k)! m^{2n-2k+1}} x^{2k} \\ &\quad + \cos(mx) \sum_{k=0}^{n-1} (-1)^{n-k+1} \frac{(2n)!}{(2k-1)! m^{2n-2k}} x^{2k+1} \\ &= (-1)^{n+1} (2n)! \left[ \sin(mx) \sum_{k=0}^n \frac{(-1)^k}{(2k)! m^{2n-2k+1}} x^{2k} \right. \\ &\quad \left. + \cos(mx) \sum_{k=1}^n \frac{(-1)^{k+1}}{(2k-3)! m^{2n-2k+2}} x^{2k-1} \right]. \end{aligned} \quad (14)$$

To find a closed form for an integral power of a cosine function,

$$I \equiv \int \cos^m x dx, \quad (15)$$

perform an INTEGRATION BY PARTS so that

$$u = \cos^{m-1} x \quad dv = \cos x dx \quad (16)$$

$$du = -(m-1) \cos^{m-2} x \sin x dx \quad v = \sin x. \quad (17)$$

Therefore

$$\begin{aligned} I &= \sin x \cos^{m-1} x + (m-1) \int \cos^{m-2} x \sin^2 x dx \\ &= \sin x \cos^{m-1} x \\ &\quad + (m-1) \left[ \int \cos^{m-2} x dx - \int \cos^m x dx \right] \\ &= \sin x \cos^{m-1} x + (m-1) \left[ \int \cos^{m-2} x dx - I \right], \end{aligned} \quad (18)$$

so

$$I[1 + (m-1)] = \sin x \cos^{m-1} x + (m-1) \int \cos^{m-2} x dx \quad (19)$$

$$\begin{aligned} I &= \int \cos^m x dx \\ &= \frac{\sin x \cos^{m-1} x}{m} + \frac{m-1}{m} \int \cos^{m-2} x dx. \end{aligned} \quad (20)$$

Now, if  $m$  is EVEN so  $m \equiv 2n$ , then

$$\begin{aligned} \int \cos^{2n} x dx &= \frac{\sin x \cos^{2n-1} x}{2n} + \frac{2n-1}{2n} \int \cos^{2n-2} x dx \\ &= \frac{\sin x \cos^{2n-1} x}{2n} + \frac{2n-1}{n} \left[ \frac{\sin x \cos^{2n-3} x}{2n-2} \right. \\ &\quad \left. + \frac{2n-3}{2n-2} \int \cos^{2n-4} x dx \right] \\ &= \sin x \left[ \frac{1}{2n} \cos^{2n-1} x + \frac{2n-1}{(2n)(2n-2)} \cos^{2n-3} x \right] \\ &\quad + \frac{(2n-1)(2n-3)}{(2n)(2n-2)} \int \cos^{2n-4} x dx \\ &= \sin x \left[ \frac{1}{2n} \cos^{2n-1} x \right. \\ &\quad \left. + \frac{2n-1}{(2n)(2n-2)} \cos^{2n-3} x + \dots \right] \\ &\quad + \frac{(2n-1)(2n-3) \dots 1}{(2n)(2n-2) \dots 2} \int \cos^0 x dx \\ &= \sin x \sum_{k=1}^n \frac{(2n-2k)!!}{(2n)!!} \frac{(2n-1)!!}{(2n-2k+1)!!} \cos^{2n-2k+1} x \\ &\quad + \frac{(2n-1)!!}{(2n)!!} x. \end{aligned} \quad (21)$$

Now let  $k' \equiv n - k + 1$ , so  $n - k = k' - 1$ ,

$$\begin{aligned} & \int \cos^{2n} x \, dx \\ &= \sin x \sum_{k=1}^n \frac{(2k-2)!!}{(2n)!!} \frac{(2n-1)!!}{(2k-1)!!} \cos^{2k-1} x + \frac{(2n-1)!!}{(2n)!!} x \\ &= \frac{(2n-1)!!}{(2n)!!} \left[ \sin x \sum_{k=0}^{n-1} \frac{(2k)!!}{(2k+1)!!} \cos^{2k+1} x + x \right]. \end{aligned} \quad (22)$$

Now if  $m$  is ODD so  $m \equiv 2n + 1$ , then

$$\begin{aligned} & \int \cos^{2n+1} x \, dx \\ &= \frac{\sin x \cos^{2n} x}{2n+1} + \frac{2n}{2n+1} \int \cos^{2n-1} x \, dx \\ &= \frac{\sin x \cos^{2n} x}{2n+1} + \frac{2n}{2n+1} \left[ \frac{\sin x \cos^{2n-2} x}{2n-1} \right. \\ & \quad \left. + \frac{2n-2}{2n-1} \int \cos^{2n-3} x \, dx \right] \\ &= \sin x \left[ \frac{1}{2n+1} \cos^{2n} x + \frac{2n}{(2n+1)(2n-1)} \cos^{2n-2} x \right] \\ & \quad + \frac{(2n)(2n-2)}{(2n+1)(2n-1)} \int \cos^{2n-3} x \, dx \\ &= \sin x \left[ \frac{1}{2n+1} \cos^{2n} x \right. \\ & \quad \left. + \frac{2n}{(2n+1)(2n-1)} \cos^{2n-2} x + \dots \right] \\ & \quad + \frac{(2n)(2n-2) \cdots 2}{(2n+1)(2n-1) \cdots 3} \int \cos x \, dx \\ &= \sin x \sum_{k=0}^n \frac{(2n-2k-1)!!}{(2n+1)!!} \frac{(2n)!!}{(2n-2k)!!} \cos^{2n-2k} x. \end{aligned} \quad (23)$$

Now let  $k' \equiv n - k$ ,

$$\int \cos^{2n} x \, dx = \frac{(2n)!!}{(2n+1)!!} \sin x \sum_{k=0}^n \frac{(2k-1)!!}{(2k)!!} \cos^{2k} x. \quad (24)$$

The general result is then

$$\int \cos^m x \, dx = \begin{cases} \frac{(2n-1)!!}{(2n)!!} \left[ \sin x \sum_{k=0}^{n-1} \frac{(2k)!!}{(2k+1)!!} \cos^{2k+1} x + x \right] & \text{for } m = 2n \\ \frac{(2n)!!}{(2n+1)!!} \sin x \sum_{k=0}^n \frac{(2k-1)!!}{(2k)!!} \cos^{2k} x & \text{for } m = 2n+1. \end{cases} \quad (25)$$

The infinite integral of a cosine times a Gaussian can also be done in closed form,

$$\int_{-\infty}^{\infty} e^{-ax^2} \cos(kx) \, dx = \sqrt{\frac{\pi}{a}} e^{-k^2/4a}. \quad (26)$$

#### Cosmological Theorem

There exists an INTEGER  $N$  such that every string in the LOOK AND SAY SEQUENCE "decays" in at most  $N$  days to a compound of "common" and "transuranic elements."

The table below gives the periodic table of atoms associated with the LOOK AND SAY SEQUENCE as named by Conway (1987). The "abundance" is the average number of occurrences for long strings out of every million atoms. The asymptotic abundances are zero for transuranic elements, and 27.246... for arsenic (As), the next rarest element. The most common element is hydrogen (H), having an abundance of 91,970.383.... The starting element is U, represented by the string "3," and subsequent terms are those giving a description of the current term: one three (13); one one, one three (1113); three ones, one three (3113), etc.

Abundance	$n$	$E_n$	$E_n$ is the derivate of $E_{n+1}$

#### Costa-Hoffman-Meeks Minimal Surface

see COSTA MINIMAL SURFACE

## Costa Minimal Surface

A complete embedded MINIMAL SURFACE of finite topology. It has no BOUNDARY and does not intersect itself. It can be represented parametrically by

$$\begin{aligned}
 x &= \frac{1}{2} \Re \left\{ -\zeta(u + iv) + \pi u + \frac{\pi^2}{4e_1} \right. \\
 &\quad \left. + \frac{\pi}{2e_1} \left[ \zeta(u + iv - \frac{1}{2}) - \zeta(u + iv - \frac{1}{2}i) \right] \right\} \\
 y &= \frac{1}{2} \Re \left\{ -i\zeta(u + iv) + \pi v + \frac{\pi^2}{4e_1} \right. \\
 &\quad \left. - \frac{\pi}{2e_1} \left[ i\zeta(u + iv - \frac{1}{2}) - i\zeta(u + iv - \frac{1}{2}i) \right] \right\} \\
 z &= \frac{1}{4} \sqrt{2\pi} \ln \left| \frac{\wp(u + iv) - e_1}{\wp(u + iv) + e_1} \right|,
 \end{aligned}$$

where  $\zeta(z)$  is the WEIERSTRASS ZETA FUNCTION,  $\wp(g_2, g_3; z)$  is the WEIERSTRASS ELLIPTIC FUNCTION,  $c = 189.07272$ ,  $e_1 = 6.87519$ , and the invariants are given by  $g_2 = c$  and  $g_3 = 0$ .

## Cosymmedian Triangles

Extend the SYMMEDIAN LINES of a TRIANGLE  $\Delta A_1 A_2 A_3$  to meet the CIRCUMCIRCLE at  $P_1, P_2, P_3$ . Then the LEMOINE POINT  $K$  of  $\Delta A_1 A_2 A_3$  is also the LEMOINE POINT of  $\Delta P_1 P_2 P_3$ . The TRIANGLES  $\Delta A_1 A_2 A_3$  and  $\Delta P_1 P_2 P_3$  are cosymmedian triangles, and have the same BROCARD CIRCLE, second BROCARD TRIANGLE, BROCARD ANGLE, BROCARD POINTS, and CIRCUMCIRCLE.

see also BROCARD ANGLE, BROCARD CIRCLE, BROCARD POINTS, BROCARD TRIANGLES, CIRCUMCIRCLE, LEMOINE POINT, SYMMEDIAN LINE

## Cotangent

The function defined by  $\cot x \equiv 1/\tan x$ , where  $\tan x$  is the TANGENT. The MACLAURIN SERIES for  $\cot x$  is

$$\begin{aligned}
 \cot x &= \frac{1}{x} - \frac{1}{3}x - \frac{1}{45}x^3 - \frac{2}{945}x^5 - \frac{1}{4725}x^7 - \dots \\
 &\quad - \frac{(-1)^{n+1} 2^{2n} B_{2n}}{(2n)!} - \dots,
 \end{aligned}$$

where  $B_n$  is a BERNOULLI NUMBER.

$$\pi \cot(\pi x) = \frac{1}{x} + 2x \sum_{n=1}^{\infty} \frac{1}{x^2 - n^2}.$$

It is known that, for  $n \geq 3$ ,  $\cot(\pi/n)$  is rational only for  $n = 4$ .

## Cotangent Bundle

The cotangent bundle of a MANIFOLD is similar to the TANGENT BUNDLE, except that it is the set  $(x, f)$  where  $x \in M$  and  $f$  is a dual vector in the TANGENT SPACE to  $x \in M$ . The cotangent bundle is denoted by  $T^*M$ .

see also TANGENT BUNDLE

**Cotes Circle Property**

$$x^{2n} + 1 = \left[ x^2 - 2x \cos \left( \frac{\pi}{2n} \right) + 1 \right] \\ \times \left[ x^2 - 2x \cos \left( \frac{3\pi}{2n} \right) + 1 \right] \times \cdots \times \\ \times \left[ x^2 - 2x \cos \left( \frac{(2n-1)\pi}{2n} \right) + 1 \right].$$

**Cotes Number**

The numbers  $\lambda_{\nu n}$  in the GAUSSIAN QUADRATURE formula

$$Q_n(f) = \sum_{\nu=1}^n \lambda_{\nu n} f(x_{\nu n}).$$

see also GAUSSIAN QUADRATURE

**References**

Cajori, F. *A History of Mathematical Notations*, Vols. 1-2. New York: Dover, p. 42, 1993.

**Cotes' Spiral**

The planar orbit of a particle under a  $r^{-3}$  force field. It is an EPISPIRAL.

**Coth**

see HYPERBOLIC COTANGENT.

**Coulomb Wave Function**

A special case of the CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND. It gives the solution to the radial Schrödinger equation in the Coulomb potential ( $1/r$ ) of a point nucleus

$$\frac{d^2 W}{d\rho^2} + \left[ 1 - \frac{2\eta}{\rho} - \frac{L(L+1)}{\rho^2} \right] W = 0. \quad (1)$$

The complete solution is

$$W = C_1 F_L(\eta, \rho) + C_2 G_L(\eta, \rho). \quad (2)$$

The Coulomb function of the first kind is

$$F_L(\eta, \rho) = C_L(\eta) \rho^{L+1} e^{-i\rho} {}_1F_1(L+1-i\eta; 2L+2; 2i\rho), \quad (3)$$

where

$$C_L(\eta) \equiv \frac{2^L e^{-\pi\eta/2} |\Gamma(L+1+i\eta)|}{\Gamma(2L+2)}, \quad (4)$$

${}_1F_1(a; b; z)$  is the CONFLUENT HYPERGEOMETRIC FUNCTION,  $\Gamma(z)$  is the GAMMA FUNCTION, and the Coulomb function of the second kind is

$$G_L(\eta, \rho) = \frac{2\eta}{C_0^2(\eta)} F_L(\eta, \rho) \left[ \ln(2\rho) + \frac{q_L(\eta)}{p_L(\eta)} \right] \\ + \frac{1}{(2L+1)C_L(\eta)} \rho^{-L} \sum_{K=-L}^{\infty} a_K^L(\eta) \rho^{K+L}, \quad (5)$$

where  $q_L$ ,  $p_L$ , and  $a_K^L$  are defined in Abramowitz and Stegun (1972, p. 538).

Abramowitz, M. and Stegun, C. A. (Eds.). "Coulomb Wave Functions." Ch. 14 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, pp. 537-544, 1972.

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 631-633, 1953.

**Count**

The largest  $n$  such that  $|z_n| < 4$  in a MANDELBROT SET. Points of different count are often assigned different colors.

**Countable Additivity Probability Axiom**

For a COUNTABLE SET of  $n$  disjoint events  $E_1, E_2, \dots, E_n$

$$P \left( \bigcup_{i=1}^n E_i \right) = \sum_{i=1}^n P(E_i).$$

see also COUNTABLE SET

**Countable Set**

A SET which is either FINITE or COUNTABLY INFINITE.

see also ALEPH-0, ALEPH-1, COUNTABLY INFINITE SET, FINITE, INFINITE, UNCOUNTABLY INFINITE SET

**Countable Space**

see FIRST-COUNTABLE SPACE

**Countably Infinite Set**

Any SET which can be put in a ONE-TO-ONE correspondence with the NATURAL NUMBERS (or INTEGERS), and so has CARDINAL NUMBER  $\aleph_0$ . Examples of countable sets include the INTEGERS and ALGEBRAIC NUMBERS. Georg Cantor showed that the number of REAL NUMBERS is rigorously larger than a countably infinite set, and the postulate that this number, the "CONTINUUM," is equal to  $\aleph_1$  is called the CONTINUUM HYPOTHESIS.

see also ALEPH-0, ALEPH-1, CANTOR DIAGONAL SLASH, CARDINAL NUMBER, CONTINUUM HYPOTHESIS, COUNTABLE SET,

**Counting Generalized Principle**

If  $r$  experiments are performed with  $n_i$  possible outcomes for each experiment  $i = 1, 2, \dots, r$ , then there are a total of  $\prod_{i=1}^r n_i$  possible outcomes.

**Counting Number**

A POSITIVE INTEGER: 1, 2, 3, 4, ... (Sloane's A000027), also called a NATURAL NUMBER. However, 0 is sometimes also included in the list of counting numbers. Due to lack of standard terminology, the following terms are recommended in preference to "counting number," "NATURAL NUMBER," and "WHOLE NUMBER."

Set	Name	Symbol
$\dots, -2, -1, 0, 1, 2, \dots$	integers	$\mathbb{Z}$
$1, 2, 3, 4, \dots$	positive integers	$\mathbb{Z}^+$
$0, 1, 2, 3, 4, \dots$	nonnegative integers	$\mathbb{Z}^*$
$-1, -2, -3, -4, \dots$	negative integers	$\mathbb{Z}^-$

see also NATURAL NUMBER, WHOLE NUMBER,  $\mathbb{Z}$ ,  $\mathbb{Z}^-$ ,  $\mathbb{Z}^+$ ,  $\mathbb{Z}^*$

### Coupon Collector's Problem

Let  $n$  objects be picked repeatedly with probability  $p_i$  that object  $i$  is picked on a given try, with

$$\sum_i p_i = 1.$$

Find the earliest time at which all  $n$  objects have been picked at least once.

### Covariance

Given  $n$  sets of variates denoted  $\{x_1\}, \dots, \{x_n\}$ , a quantity called the COVARIANCE MATRIX is defined by

$$V_{ij} = \text{cov}(x_i, x_j) \quad (1)$$

$$\equiv \langle (x_i - \mu_i)(x_j - \mu_j) \rangle \quad (2)$$

$$= \langle x_i x_j \rangle - \langle x_i \rangle \langle x_j \rangle, \quad (3)$$

where  $\mu_i = \langle x_i \rangle$  and  $\mu_j = \langle x_j \rangle$  are the MEANS of  $x_i$  and  $x_j$ , respectively. An individual element  $V_{ij}$  of the COVARIANCE MATRIX is called the covariance of the two variates  $x_i$  and  $x_j$ , and provides a measure of how strongly correlated these variables are. In fact, the derived quantity

$$\text{cor}(x_i, x_j) \equiv \frac{\text{cov}(x_i, x_j)}{\sigma_i \sigma_j}, \quad (4)$$

where  $\sigma_i, \sigma_j$  are the STANDARD DEVIATIONS, is called the CORRELATION of  $x_i$  and  $x_j$ . Note that if  $x_i$  and  $x_j$  are taken from the same set of variates (say,  $x$ ), then

$$\text{cov}(x, x) = \langle x^2 \rangle - \langle x \rangle^2 = \text{var}(x), \quad (5)$$

giving the usual VARIANCE  $\text{var}(x)$ . The covariance is also symmetric since

$$\text{cov}(x, y) = \text{cov}(y, x). \quad (6)$$

For two variables, the covariance is related to the VARIANCE by

$$\text{var}(x + y) = \text{var}(x) + \text{var}(y) + 2 \text{cov}(x, y). \quad (7)$$

For two independent variates  $x = x_i$  and  $y = x_j$ ,

$$\text{cov}(x, y) = \langle xy \rangle - \mu_x \mu_y = \langle x \rangle \langle y \rangle - \mu_x \mu_y = 0, \quad (8)$$

so the covariance is zero. However, if the variables are correlated in some way, then their covariance will be NONZERO. In fact, if  $\text{cov}(x, y) > 0$ , then  $y$  tends to increase as  $x$  increases. If  $\text{cov}(x, y) < 0$ , then  $y$  tends to decrease as  $x$  increases.

The covariance obeys the identity

$$\begin{aligned} \text{cov}(x + z, y) &= \langle (x + z)y \rangle - \langle x + z \rangle \langle y \rangle \\ &= \langle xy \rangle + \langle zy \rangle - (\langle x \rangle + \langle z \rangle) \langle y \rangle \\ &= \langle xy \rangle - \langle x \rangle \langle y \rangle + \langle zy \rangle - \langle z \rangle \langle y \rangle \\ &= \text{cov}(x, y) + \text{cov}(z, y). \end{aligned} \quad (9)$$

By induction, it therefore follows that

$$\text{cov} \left( \sum_{i=1}^n x_i, y \right) = \sum_{i=1}^n \text{cov}(x_i, y) \quad (10)$$

$$\text{cov} \left( \sum_{i=1}^n x_i, \sum_{j=1}^m y_j \right) = \sum_{i=1}^n \text{cov} \left( x_i, \sum_{j=1}^m y_j \right) \quad (11)$$

$$= \sum_{i=1}^n \text{cov} \left( \sum_{j=1}^m y_j, x_i \right) \quad (12)$$

$$= \sum_{i=1}^n \sum_{j=1}^m \text{cov}(y_j, x_i) \quad (13)$$

$$= \sum_{i=1}^n \sum_{j=1}^m \text{cov}(x_i, y_j). \quad (14)$$

see also CORRELATION (STATISTICAL), COVARIANCE MATRIX, VARIANCE

### Covariance Matrix

Given  $n$  sets of variates denoted  $\{x_1\}, \dots, \{x_n\}$ , the first-order covariance matrix is defined by

$$V_{ij} = \text{cov}(x_i, x_j) \equiv \langle (x_i - \mu_i)(x_j - \mu_j) \rangle,$$

where  $\mu_i$  is the MEAN. Higher order matrices are given by

$$V_{ij}^{mn} = \langle (x_i - \mu_i)^m (x_j - \mu_j)^n \rangle.$$

An individual matrix element  $V_{ij} = \text{cov}(x_i, x_j)$  is called the COVARIANCE of  $x_i$  and  $x_j$ .

see also CORRELATION (STATISTICAL), COVARIANCE, VARIANCE

**Covariant Derivative**

The covariant derivative of a TENSOR  $A^\alpha$  (also called the SEMICOLON DERIVATIVE since its symbol is a semicolon)

$$A^\alpha{}_{;\alpha} = \nabla \cdot \mathbf{A} = A^k{}_{,k} + \Gamma^k_{jk} A^j, \quad (1)$$

and of  $A_j$  is

$$A_{j;k} = \frac{1}{g^{kk}} \frac{\partial A_j}{\partial x_k} - \Gamma^i_{jk} A_i, \quad (2)$$

where  $\Gamma$  is a CONNECTION COEFFICIENT.

see also CONNECTION COEFFICIENT, COVARIANT TENSOR, DIVERGENCE

**References**

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 48–50, 1953.

**Covariant Tensor**

A covariant tensor is a TENSOR having specific transformation properties (c.f., a CONTRAVARIANT TENSOR). To examine the transformation properties of a covariant tensor, first consider the GRADIENT

$$\nabla \phi \equiv \frac{\partial \phi}{\partial x_1} \hat{\mathbf{x}}_1 + \frac{\partial \phi}{\partial x_2} \hat{\mathbf{x}}_2 + \frac{\partial \phi}{\partial x_3} \hat{\mathbf{x}}_3, \quad (1)$$

for which

$$\frac{\partial \phi'}{\partial x'_i} = \frac{\partial \phi}{\partial x_j} \frac{\partial x_j}{\partial x'_i}, \quad (2)$$

where  $\phi(x_1, x_2, x_3) = \phi'(x'_1, x'_2, x'_3)$ . Now let

$$A_i \equiv \frac{\partial \phi}{\partial x_i}, \quad (3)$$

then any set of quantities  $A_j$  which transform according to

$$A'_i = \frac{\partial x_j}{\partial x'_i} A'_j \quad (4)$$

or, defining

$$a_{ij} \equiv \frac{\partial x_j}{\partial x'_i}, \quad (5)$$

according to

$$A_i = a_{ij} A'_j \quad (6)$$

is a covariant tensor. Covariant tensors are indicated with lowered indices, i.e.,  $a_\mu$ .

CONTRAVARIANT TENSORS are a type of TENSOR with differing transformation properties, denoted  $a^\nu$ . However, in 3-D CARTESIAN COORDINATES,

$$\frac{\partial x_j}{\partial x'_i} = \frac{\partial x'_i}{\partial x_j} \equiv a_{ij} \quad (7)$$

for  $i, j = 1, 2, 3$ , meaning that contravariant and covariant tensors are equivalent. The two types of tensors do

differ in higher dimensions, however. Covariant FOUR-VECTORS satisfy

$$a_\mu = \Lambda^\nu_\mu a_\nu, \quad (8)$$

where  $\Lambda$  is a LORENTZ TENSOR.

To turn a CONTRAVARIANT TENSOR into a covariant tensor, use the METRIC TENSOR  $g_{\mu\nu}$  to write

$$a_\mu \equiv g_{\mu\nu} a^\nu. \quad (9)$$

Covariant and contravariant indices can be used simultaneously in a MIXED TENSOR.

see also CONTRAVARIANT TENSOR, FOUR-VECTOR, LORENTZ TENSOR, METRIC TENSOR, MIXED TENSOR, TENSOR

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 44–46, 1953.

**Covariant Vector**

A COVARIANT TENSOR of RANK 1.

**Cover**

A group  $C$  of SUBSETS of  $X$  whose UNION contains the given set  $X$  ( $\cup\{S : S \in C\} = X$ ) is called a cover (or a COVERING). A MINIMAL COVER is a cover for which removal of one member destroys the covering property. There are various types of specialized covers, including proper covers, antichain covers, minimal covers,  $k$ -covers, and  $k^*$ -covers. The number of possible covers for a set of  $N$  elements is

$$|C(N)| = \frac{1}{2} \sum_{k=0}^N (-1)^k \binom{N}{k} 2^{2^{N-k}},$$

the first few of which are 1, 5, 109, 32297, 2147321017, 9223372023970362989, ... (Sloane's A003465). The number of proper covers for a set of  $N$  elements is

$$\begin{aligned} |C'(N)| &= |C(N)| - \frac{1}{4} 2^{2^N} \\ &= \frac{1}{2} \sum_{k=0}^N (-1)^k \binom{N}{k} 2^{2^{N-k}} - \frac{2^{2^N}}{4}, \end{aligned}$$

the first few of which are 0, 1, 45, 15913, 1073579193, ... (Sloane's A007537).

**Cover Relation**

The transitive reflexive reduction of a PARTIAL ORDER. An element  $z$  of a POSET  $(X, \leq)$  covers another element  $x$  provided that there exists no third element  $y$  in the poset for which  $x \leq y \leq z$ . In this case,  $z$  is called an "upper cover" of  $x$  and  $x$  a "lower cover" of  $z$ .

**Covering**

see COVER

**Covering Dimension**

see LEBESGUE COVERING DIMENSION

**Covering System**

A system of congruences  $a_i \bmod n_i$  with  $1 \leq i \leq k$  is called a covering system if every INTEGER  $y$  satisfies  $y \equiv a_i \pmod{n_i}$  for at least one value of  $i$ .

**References**

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, p. 78, 1972.

**Cox's Theorem**

Let  $\sigma_1, \dots, \sigma_4$  be four PLANES in GENERAL POSITION through a point  $P$  and let  $P_{ij}$  be a point on the LINE  $\sigma_i \cdot \sigma_j$ . Let  $\sigma_{ijk}$  denote the PLANE  $P_{ij}P_{ik}P_{jk}$ . Then the four PLANES  $\sigma_{234}, \sigma_{134}, \sigma_{124}, \sigma_{123}$  all pass through one point  $P_{1234}$ . Similarly, let  $\sigma_1, \dots, \sigma_5$  be five PLANES in GENERAL POSITION through  $P$ . Then the five points  $P_{2345}, P_{1345}, P_{1245}, P_{1235}$ , and  $P_{1234}$  all lie in one PLANE. And so on.

see also CLIFFORD'S CIRCLE THEOREM

**Coxeter Diagram**

see COXETER-DYKIN DIAGRAM

**Coxeter-Dynkin Diagram**

A labeled graph whose nodes are indexed by the generators of a COXETER GROUP having  $(P_i, P_j)$  as an EDGE labeled by  $M_{ij}$  whenever  $M_{ij} > 2$ , where  $M_{ij}$  is an element of the COXETER MATRIX. Coxeter-Dynkin diagrams are used to visualize COXETER GROUPS. A Coxeter-Dynkin diagram is associated with each RATIONAL DOUBLE POINT (Fischer 1986).

**Coxeter's Loxodromic Sequence of Tangent Circles**

An infinite sequence of CIRCLES such that every four consecutive CIRCLES are mutually tangent, and the CIRCLES' RADII  $\dots, R_{-n}, \dots, R_{-1}, R_0, R_1, R_2, R_3, R_4, \dots, R_n, R_n + 1, \dots$ , are in GEOMETRIC PROGRESSION with ratio

$$k \equiv \frac{R_{n+1}}{R_n} = \phi + \sqrt{\phi},$$

where  $\phi$  is the GOLDEN RATIO (Gardner 1979ab). Coxeter (1968) generalized the sequence to SPHERES.

see also ARBELOS, GOLDEN RATIO, HEXLET, PAPPUS CHAIN, STEINER CHAIN

### Coxeter Matrix

An  $n \times n$  SQUARE MATRIX  $M$  with

$$\begin{aligned} M_{ii} &= 1 \\ M_{ij} &= M_{ji} > 1 \end{aligned}$$

for all  $i, j = 1, \dots, n$ .

see also COXETER GROUP

### Coxeter-Todd Lattice

The complex LATTICE  $\Lambda_6^\omega$  corresponding to real lattice  $K_{12}$  having the densest HYPERSPHERE PACKING (KISSING NUMBER) in 12-D. The associated AUTOMORPHISM GROUP  $G_0$  was discovered by Mitchell (1914). The order of  $G_0$  is given by

$$|\text{Aut}(\Lambda_6^\omega)| = 2^9 \cdot 3^7 \cdot 5 \cdot 7 = 39,191,040.$$

The order of the AUTOMORPHISM GROUP of  $K_{12}$  is given by

$$|\text{Aut}(K_{12})| = 2^{10} \cdot 3^7 \cdot 5 \cdot 7$$

(Conway and Sloane 1983).

### Cramér-Euler Paradox

A curve of order  $n$  is generally determined by  $n(n+3)/2$  points. So a CONIC SECTION is determined by five points and a CUBIC CURVE should require nine. But the MACLAURIN-BEZOUT THEOREM says that two curves of degree  $n$  intersect in  $n^2$  points, so two CUBICS intersect in nine points. This means that  $n(n+3)/2$  points do not always uniquely determine a single curve of order  $n$ . The paradox was publicized by Stirling, and explained by Plücker.

see also CUBIC CURVE, MACLAURIN-BEZOUT THEOREM

### Cramer's Rule

Given a set of linear equations

$$\begin{cases} a_1x + b_1y + c_1z = d_1 \\ a_2x + b_2y + c_2z = d_2 \\ a_3x + b_3y + c_3z = d_3, \end{cases} \quad (1)$$

consider the DETERMINANT

$$D \equiv \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}. \quad (2)$$

Now multiply  $D$  by  $x$ , and use the property of DETERMINANTS that MULTIPLICATION by a constant is equivalent to MULTIPLICATION of each entry in a given row by that constant

$$x \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} a_1x & b_1 & c_1 \\ a_2x & b_2 & c_2 \\ a_3x & b_3 & c_3 \end{vmatrix}. \quad (3)$$

Another property of DETERMINANTS enables us to add a constant times any column to any column and obtain the same DETERMINANT, so add  $y$  times column 2 and  $z$  times column 3 to column 1,

$$xD = \begin{vmatrix} a_1x + b_1y + c_1z & b_1 & c_1 \\ a_2x + b_2y + c_2z & b_2 & c_2 \\ a_3x + b_3y + c_3z & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} d_1 & b_1 & c_1 \\ d_2 & b_2 & c_2 \\ d_3 & b_3 & c_3 \end{vmatrix}. \quad (4)$$

If  $\mathbf{d} = \mathbf{0}$ , then (4) reduces to  $xD = 0$ , so the system has nondegenerate solutions (i.e., solutions other than  $(0, 0, 0)$ ) only if  $D = 0$  (in which case there is a family of solutions). If  $\mathbf{d} \neq \mathbf{0}$  and  $D = 0$ , the system has no unique solution. If instead  $\mathbf{d} \neq \mathbf{0}$  and  $D \neq 0$ , then solutions are given by

$$x = \frac{\begin{vmatrix} d_1 & b_1 & c_1 \\ d_2 & b_2 & c_2 \\ d_3 & b_3 & c_3 \end{vmatrix}}{D}, \quad (5)$$

and similarly for

$$y = \frac{\begin{vmatrix} a_1 & d_1 & c_1 \\ a_2 & d_2 & c_2 \\ a_3 & d_3 & c_3 \end{vmatrix}}{D} \quad (6)$$

$$z = \frac{\begin{vmatrix} a_1 & b_1 & d_1 \\ a_2 & b_2 & d_2 \\ a_3 & b_3 & d_3 \end{vmatrix}}{D}. \quad (7)$$

This procedure can be generalized to a set of  $n$  equations so, given a system of  $n$  linear equations

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} = \begin{bmatrix} d_1 \\ \vdots \\ d_n \end{bmatrix}, \quad (8)$$

let

$$D \equiv \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix}. \quad (9)$$

If  $\mathbf{d} = \mathbf{0}$ , then nondegenerate solutions exist only if  $D = 0$ . If  $\mathbf{d} \neq \mathbf{0}$  and  $D = 0$ , the system has no unique solution. Otherwise, compute

$$D_k \equiv \begin{vmatrix} a_{11} & \cdots & a_{1(k-1)} & d_1 & a_{1(k+1)} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{n(k-1)} & d_n & a_{n(k+1)} & \cdots & a_{nn} \end{vmatrix}. \quad (10)$$

Then  $x_k = D_k/D$  for  $1 \leq k \leq n$ . In the 3-D case, the VECTOR analog of Cramer's rule is

$$(\mathbf{A} \times \mathbf{B}) \times (\mathbf{C} \times \mathbf{D}) = (\mathbf{A} \cdot \mathbf{B} \times \mathbf{D})\mathbf{C} - (\mathbf{A} \cdot \mathbf{B} \times \mathbf{C})\mathbf{D}. \quad (11)$$

see also DETERMINANT, LINEAR ALGEBRA, MATRIX, SYSTEM OF EQUATIONS, VECTOR

### Cramér's Theorem

If  $X$  and  $Y$  are INDEPENDENT variates and  $X + Y$  is a GAUSSIAN DISTRIBUTION, then both  $X$  and  $Y$  must have GAUSSIAN DISTRIBUTIONS. This was proved by Cramér in 1936.

### Craps

A game played with two DICE. If the total is 7 or 11 (a "natural"), the thrower wins and retains the DICE for another throw. If the total is 2, 3, or 12 ("craps"), the thrower loses but retains the DICE. If the total is any other number (called the thrower's "point"), the thrower must continue throwing and roll the "point" value again before throwing a 7. If he succeeds, he wins and retains the DICE, but if a 7 appears first, the player loses and passes the dice. The probability of winning is  $244/495 \approx 0.493$  (Kraitchik 1942).

### Creative Telescoping

see TELESCOPING SUM, ZEILBERGER'S ALGORITHM

### Cremona Transformation

An entire Cremona transformation is a BIRATIONAL TRANSFORMATION of the PLANE. Cremona transformations are MAPS of the form

$$x_{i+1} = f(x_i, y_i)$$

$$y_{i+1} = g(x_i, y_i),$$

in which  $f$  and  $g$  are POLYNOMIALS. A quadratic Cremona transformation is always factorable.

### Cribbage

Cribbage is a game in which each of two players is dealt a hand of six CARDS. Each player then discards two of his six cards to a four-card "crib" which alternates between players. After the discard, the top card in the remaining deck is turned up. Cards are then alternating played out by the two players, with points being scored for pairs, runs, cumulative total of 15 and 31, and playing the last possible card ("go") not giving a total over 31. All face cards are counted as 10 for the purpose of playing out, but the normal values of Jack = 11, Queen = 12, King = 13 are used to determine runs. Aces are always low (ace = 1). After all cards have been played, each player counts the four cards in his hand taken in conjunction with the single top card. Points are awarded for pairs, flushes, runs, and combinations of cards giving 15. A Jack having the same suit as a top card is awarded an additional point for "nobbs." The crib is then also counted and scored. The winner is the first person to "peg" a certain score, as recorded on a "cribbage board."

The best possible score in a hand is 29, corresponding to three 5s and a Jack with a top 5 the same suit as the Jack. Hands with scores of 25, 26, and 27 are not possible.

### Criss-Cross Method

A standard form of the LINEAR PROGRAMMING problem of maximizing a linear function over a CONVEX POLYHEDRON is to maximize  $\mathbf{c} \cdot \mathbf{x}$  subject to  $\mathbf{m}\mathbf{x} \leq \mathbf{b}$  and  $\mathbf{x} \geq \mathbf{0}$ , where  $\mathbf{m}$  is a given  $s \times d$  matrix,  $\mathbf{c}$  and  $\mathbf{b}$  are given  $d$ -vector and  $s$ -vectors, respectively. The Criss-cross method always finds a VERTEX solution if an optimal solution exists.

see also CONVEX POLYHEDRON, LINEAR PROGRAMMING, VERTEX (POLYHEDRON)

### Criterion

A requirement NECESSARY for a given statement or theorem to hold. Also called a CONDITION.

see also BROWN'S CRITERION, CAUCHY CRITERION, EULER'S CRITERION, GAUSS'S CRITERION, KORSELT'S CRITERION, LEIBNIZ CRITERION, POCKLINGTON'S CRITERION, VANDIVER'S CRITERIA, WEYL'S CRITERION

### Critical Line

The LINE  $\Re(s) = 1/2$  in the COMPLEX PLANE on which the RIEMANN HYPOTHESIS asserts that all nontrivial (COMPLEX) ROOTS of the RIEMANN ZETA FUNCTION  $\zeta(s)$  lie. Although it is known that an INFINITE number of zeros lie on the critical line and that these comprise at least 40% of all zeros, the RIEMANN HYPOTHESIS is still unproven.

see also RIEMANN HYPOTHESIS, RIEMANN ZETA FUNCTION

### References

Vardi, I. *Computational Recreations in Mathematics*. Reading, MA: Addison-Wesley, p. 142, 1991.

### Critical Point

A FUNCTION  $y = f(x)$  has critical points at all points  $x_0$  where  $f'(x_0) = 0$  or  $f(x)$  is not DIFFERENTIABLE. A FUNCTION  $z = f(x, y)$  has critical points where the GRADIENT  $\nabla f = 0$  or  $\partial f / \partial x$  or the PARTIAL DERIVATIVE  $\partial f / \partial y$  is not defined.

### Crook

A 6-POLYAMOND.

### References

Golomb, S. W. *Polyominoes: Puzzles, Patterns, Problems, and Packings*, 2nd ed. Princeton, NJ: Princeton University Press, p. 92, 1994.

### Crookedness

Let a KNOT  $K$  be parameterized by a VECTOR FUNCTION  $\mathbf{v}(t)$  with  $t \in \mathbb{S}^1$ , and let  $\mathbf{w}$  be a fixed UNIT VECTOR in  $\mathbb{R}^3$ . Count the number of RELATIVE MINIMA of the projection function  $\mathbf{w} \cdot \mathbf{v}(t)$ . Then the MINIMUM such number over all directions  $\mathbf{w}$  and all  $K$  of the given type is called the crookedness  $\mu(K)$ . Milnor (1950) showed that  $2\pi\mu(K)$  is the INFIMUM of the total curvature of  $K$ . For any TAME KNOT  $K$  in  $\mathbb{R}^3$ ,  $\mu(K) = b(K)$  where  $b(K)$  is the BRIDGE INDEX.

see also BRIDGE INDEX

### Cross

In general, a cross is a figure formed by two intersecting LINE SEGMENTS. In LINEAR ALGEBRA, a cross is defined as a set of  $n$  mutually PERPENDICULAR pairs of VECTORS of equal magnitude from a fixed origin in EUCLIDEAN  $n$ -SPACE.

The word "cross" is also used to denote the operation of the CROSS PRODUCT, so  $\mathbf{a} \times \mathbf{b}$  would be pronounced "a cross b."

see also CROSS PRODUCT, DOT, EUTACTIC STAR, GAULLIST CROSS, GREEK CROSS, LATIN CROSS, MALTESE CROSS, PAPAL CROSS, SAINT ANDREW'S CROSS, SAINT ANTHONY'S CROSS, STAR

### Cross-Cap

The self-intersection of a one-sided SURFACE. It can be described as a circular HOLE which, when entered, exits from its opposite point (from a topological viewpoint, both singular points on the cross-cap are equivalent). The cross-cap has a segment of double points which terminates at two "PINCH POINTS" known as WHITNEY SINGULARITIES.

The cross-cap can be generated using the general method for NONORIENTABLE SURFACES using the polynomial function

$$\mathbf{f}(x, y, z) = (xz, yz, \frac{1}{2}(z^2 - x^2)) \quad (1)$$

(Pinkall 1986). Transforming to SPHERICAL COORDINATES gives

$$x(u, v) = \frac{1}{2} \cos u \sin(2v) \quad (2)$$

$$y(u, v) = \frac{1}{2} \sin u \sin(2v) \quad (3)$$

$$z(u, v) = \frac{1}{2} (\cos^2 v - \cos^2 u \sin^2 v) \quad (4)$$

for  $u \in [0, 2\pi)$  and  $v \in [0, \pi/2]$ . To make the equations slightly simpler, all three equations are normally multiplied by a factor of 2 to clear the arbitrary scaling constant. Three views of the cross-cap generated using this equation are shown above. Note that the middle one looks suspiciously like MAEDER'S OWL MINIMAL SURFACE.

Another representation is

$$f(x, y, z) = (yz, 2xy, x^2 - y^2), \quad (5)$$

(Gray 1993), giving parametric equations

$$x = \frac{1}{2} \sin u \sin(2v) \quad (6)$$

$$y = \sin(2u) \sin^2 v \quad (7)$$

$$z = \cos(2u) \sin^2 v, \quad (8)$$

(Geometry Center) where, for aesthetic reasons, the  $y$ - and  $z$ -coordinates have been multiplied by 2 to produce a squashed, but topologically equivalent, surface. Nordstrand gives the implicit equation

$$4x^2(x^2 + y^2 + z^2 + z) + y^2(y^2 + z^2 - 1) = 0 \quad (9)$$

which can be solved for  $z$  to yield

$$z = \frac{-2x^2 \pm \sqrt{(y^2 + 2x^2)(1 - 4x^2 - y^2)}}{4x^2 + y^2}. \quad (10)$$

Taking the inversion of a cross-cap such that  $(0, 0, -1/2)$  is sent to  $\infty$  gives a CYLINDROID, shown above (Pinkall 1986).

The cross-cap is one of the three possible SURFACES obtained by sewing a MÖBIUS STRIP to the edge of a DISK. The other two are the BOY SURFACE and ROMAN SURFACE.

see also BOY SURFACE, MÖBIUS STRIP, NONORIENTABLE SURFACE, PROJECTIVE PLANE, ROMAN SURFACE

#### Cross-Correlation

Let  $\star$  denote cross-correlation. Then the cross-correlation of two functions  $f(t)$  and  $g(t)$  of a real variable  $t$  is defined by

$$f \star g \equiv f^*(-t) * g(t), \quad (1)$$

where  $*$  denotes CONVOLUTION and  $f^*(t)$  is the COMPLEX CONJUGATE of  $f(t)$ . The CONVOLUTION is defined by

$$f(t) * g(t) = \int_{-\infty}^{\infty} f(\tau)g(t - \tau)d\tau, \quad (2)$$

therefore

$$f \star g \equiv \int_{-\infty}^{\infty} f^*(-\tau)g(t - \tau)d\tau. \quad (3)$$

Let  $\tau' \equiv -\tau$ , so  $d\tau' = -d\tau$  and

$$\begin{aligned} f \star g &= \int_{\infty}^{-\infty} f^*(\tau')g(t + \tau')(-d\tau') \\ &= \int_{-\infty}^{\infty} f^*(\tau)g(t + \tau)d\tau. \end{aligned} \quad (4)$$

The cross-correlation satisfies the identity

$$(g \star h) \star (g \star h) = (g \star g) \star (h \star h). \quad (5)$$

If  $f$  or  $g$  is EVEN, then

$$f \star g = f * g, \quad (6)$$

where  $*$  denotes CONVOLUTION.

see also AUTOCORRELATION, CONVOLUTION, CROSS-CORRELATION THEOREM

#### Cross-Correlation Coefficient

The COEFFICIENT  $\rho$  in a GAUSSIAN BIVARIATE DISTRIBUTION.

#### Cross-Correlation Theorem

Let  $f \star g$  denote the CROSS-CORRELATION of functions  $f(t)$  and  $g(t)$ . Then

$$\begin{aligned} f \star g &= \int_{-\infty}^{\infty} f^*(\tau)g(t + \tau)d\tau \\ &= \int_{-\infty}^{\infty} \left[ \int_{-\infty}^{\infty} F^*(\nu)e^{2\pi i\nu\tau}d\nu \int_{-\infty}^{\infty} G(\nu')e^{-2\pi i\nu'(t+\tau)}d\nu' \right] d\tau \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} F^*(\nu)G(\nu')e^{-2\pi i\tau(\nu'-\nu)}e^{-2\pi i\nu't}d\tau d\nu d\nu' \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} F^*(\nu)G(\nu')e^{-2\pi i\nu't} \left[ \int_{-\infty}^{\infty} e^{-2\pi i\tau(\nu'-\nu)}d\tau \right] d\nu d\nu' \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} F^*(\nu)G(\nu')e^{-2\pi i\nu't}\delta(\nu' - \nu)d\nu' d\nu \\ &= \int_{-\infty}^{\infty} F^*(\nu)G(\nu)e^{-2\pi i\nu't}d\nu \\ &= \mathcal{F}[F^*(\nu)G(\nu)], \end{aligned} \quad (1)$$

where  $\mathcal{F}$  denotes the FOURIER TRANSFORM and

$$f(t) \equiv \mathcal{F}[F(\nu)] = \int_{-\infty}^{\infty} F(\nu) e^{-2\pi i \nu t} dt \quad (2)$$

$$g(t) \equiv \mathcal{F}[G(\nu)] = \int_{-\infty}^{\infty} G(\nu) e^{-2\pi i \nu t} dt. \quad (3)$$

Applying a FOURIER TRANSFORM on each side gives the cross-correlation theorem,

$$f \star g = \mathcal{F}[F^*(\nu)G(\nu)]. \quad (4)$$

If  $F = G$ , then the cross-correlation theorem reduces to the WIENER-KHINTCHINE THEOREM.

see also FOURIER TRANSFORM, WIENER-KHINTCHINE THEOREM

### Cross Curve

see CRUCIFORM

### Cross Fractal

see CANTOR SQUARE FRACTAL

### Cross of Lorraine

see GAULLIST CROSS

### Cross Polytope

A regular POLYTOPE in  $n$ -D (generally assumed to satisfy  $n \geq 5$ ) corresponding to the CONVEX HULL of the points formed by permuting the coordinates  $(\pm 1, 0, 0, \dots, 0)$ . It is denoted  $\beta_n$  and has SCHLÄFLI SYMBOL  $\{3^{n-2}, 4\}$ . In 3-D, the cross polytope is the OCTAHEDRON.

see also MEASURE POLYTOPE, SIMPLEX

### Cross Product

For VECTORS  $\mathbf{u}$  and  $\mathbf{v}$ ,

$$\mathbf{u} \times \mathbf{v} = \hat{\mathbf{x}}(u_y v_z - u_z v_y) - \hat{\mathbf{y}}(u_x v_z - u_z v_x) + \hat{\mathbf{z}}(u_x v_y - u_y v_x). \quad (1)$$

This can be written in a shorthand NOTATION which takes the form of a DETERMINANT

$$\mathbf{u} \times \mathbf{v} = \begin{vmatrix} \hat{\mathbf{x}} & \hat{\mathbf{y}} & \hat{\mathbf{z}} \\ u_x & u_y & u_z \\ v_x & v_y & v_z \end{vmatrix}. \quad (2)$$

It is also true that

$$|\mathbf{u} \times \mathbf{v}| = |\mathbf{u}| |\mathbf{v}| \sin \theta, \quad (3)$$

$$= |\mathbf{u}| |\mathbf{v}| \sqrt{1 - (\hat{\mathbf{u}} \cdot \hat{\mathbf{v}})^2}, \quad (4)$$

where  $\theta$  is the angle between  $\mathbf{u}$  and  $\mathbf{v}$ , given by the DOT PRODUCT

$$\cos \theta \equiv \hat{\mathbf{u}} \cdot \hat{\mathbf{v}}. \quad (5)$$

Identities involving the cross product include

$$\frac{d}{dt} [\mathbf{r}_1(t) \times \mathbf{r}_2(t)] = \mathbf{r}_1(t) \times \frac{d\mathbf{r}_2}{dt} + \frac{d\mathbf{r}_1}{dt} \times \mathbf{r}_2(t) \quad (6)$$

$$\mathbf{A} \times \mathbf{B} = -\mathbf{B} \times \mathbf{A} \quad (7)$$

$$\mathbf{A} \times (\mathbf{B} + \mathbf{C}) = \mathbf{A} \times \mathbf{B} + \mathbf{A} \times \mathbf{C} \quad (8)$$

$$(t\mathbf{A}) \times \mathbf{B} = t(\mathbf{A} \times \mathbf{B}). \quad (9)$$

For a proof that  $\mathbf{A} \times \mathbf{B}$  is a PSEUDOVECTOR, see Arfken (1985, pp. 22-23). In TENSOR notation,

$$\mathbf{A} \times \mathbf{B} = \epsilon_{ijk} A^j B^k, \quad (10)$$

where  $\epsilon_{ijk}$  is the LEVI-CIVITA TENSOR.

see also DOT PRODUCT, SCALAR TRIPLE PRODUCT

### Cross-Ratio

$$[a, b, c, d] \equiv \frac{(a-b)(c-d)}{(a-d)(c-b)}. \quad (1)$$

For a MÖBIUS TRANSFORMATION  $f$ ,

$$[a, b, c, d] = [f(a), f(b), f(c), f(d)]. \quad (2)$$

There are six different values which the cross-ratio may take, depending on the order in which the points are chosen. Let  $\lambda \equiv [a, b, c, d]$ . Possible values of the cross-ratio are then  $\lambda$ ,  $1 - \lambda$ ,  $1/\lambda$ ,  $(\lambda - 1)/\lambda$ ,  $1/(1 - \lambda)$ , and  $\lambda/(\lambda - 1)$ .

Given lines  $a$ ,  $b$ ,  $c$ , and  $d$  which intersect in a point  $O$ , let the lines be cut by a line  $l$ , and denote the points of intersection of  $l$  with each line by  $A$ ,  $B$ ,  $C$ , and  $D$ . Let the distance between points  $A$  and  $B$  be denoted  $AB$ , etc. Then the cross-ratio

$$[AB, CD] \equiv \frac{(AB)(CD)}{(BC)(AD)} \quad (3)$$

is the same for any position of the  $l$  (Coxeter and Greitzer 1967). Note that the definitions  $(AB/AD)/(BC/CD)$  and  $(CA/CB)/(DA/DB)$  are used instead by Kline (1990) and Courant and Robbins (1966), respectively. The identity

$$[AD, BC] + [AB, DC] = 1 \quad (4)$$

holds IFF  $AC//BD$ , where  $//$  denotes SEPARATION.

The cross-ratio of four points on a radial line of an INVERSION CIRCLE is preserved under INVERSION (Ogilvy 1990, p. 40).

## Cross-Section

The cross-section of a SOLID is a LAMINA obtained by its intersection with a PLANE. The cross-section of an object therefore represents an infinitesimal “slice” of a solid, and may be different depending on the orientation of the slicing plane. While the cross-section of a SPHERE is always a DISK, the cross-section of a CUBE may be a SQUARE, HEXAGON, or other shape.

## Crossed Ladders Problem

Given two crossed LADDERS resting against two buildings, what is the distance between the buildings? Let the height at which they cross be  $c$  and the lengths of the LADDERS  $a$  and  $b$ . The height at which  $b$  touches the building  $k$  is then obtained by solving

$$k^4 - 2ck^3 + k^2(a^2 - b^2) - 2ck(a^2 - b^2) + c^2(a^2 - b^2) = 0.$$

Call the horizontal distance from the top of  $a$  to the crossing  $u$ , and the distance from the top of  $b$ ,  $v$ . Call the height at which  $a$  touches the building  $h$ . There are solutions in which  $a$ ,  $b$ ,  $h$ ,  $k$ ,  $u$ , and  $v$  are all INTEGERS. One is  $a = 119$ ,  $b = 70$ ,  $c = 30$ , and  $u + v = 56$ .

## Crossing Number (Graph)

Given a “good” GRAPH (i.e., one for which all intersecting EDGES intersect in a single point and arise from four distinct VERTICES), the crossing number is the minimum possible number of crossings with which the GRAPH can be drawn. A GRAPH with crossing number 0 is a PLANAR GRAPH. Garey and Johnson (1983) showed that determining the crossing number is an NP-COMplete PROBLEM. GUY'S CONJECTURE suggests that the crossing number for the COMPLETE GRAPH  $K_n$  is

$$\frac{1}{4} \left\lfloor \frac{n}{2} \right\rfloor \left\lfloor \frac{n-1}{2} \right\rfloor \left\lfloor \frac{n-2}{2} \right\rfloor \left\lfloor \frac{n-3}{2} \right\rfloor, \quad (1)$$

which can be rewritten

$$\begin{cases} \frac{1}{64}n(n-2)^2(n-4) & \text{for } n \text{ even} \\ \frac{1}{64}(n-1)^2(n-3)^2 & \text{for } n \text{ odd.} \end{cases} \quad (2)$$

The first few predicted and known values are given in the following table (Sloane's A000241).

Order	Predicted	Known
1	0	0
2	0	0
3	0	0
4	0	0
5	1	1
6	3	3
7	9	9
8	18	18
9	36	36
10	60	60
11	100	
12	150	
13	225	
14	315	
15	441	
16	588	

ZARANKIEWICZ'S CONJECTURE asserts that the crossing number for a COMPLETE BIGRAPH is

$$\left\lfloor \frac{n}{2} \right\rfloor \left\lfloor \frac{n-1}{2} \right\rfloor \left\lfloor \frac{m}{2} \right\rfloor \left\lfloor \frac{m-1}{2} \right\rfloor. \quad (3)$$

It has been checked up to  $m, n = 7$ , and Zarankiewicz has shown that, in general, the FORMULA provides an upper bound to the actual number. The table below gives known results. When the number is not known exactly, the prediction of ZARANKIEWICZ'S CONJECTURE is given in parentheses.

	1	2	3	4	5	6	7
1	0	0	0	0	0	0	0
2		0	0	0	0	0	0
3			1	2	4	6	9
4				4	8	12	18
5					16	24	36
6						36	54
7							77, 79, or (81)

Consider the crossing number for a rectilinear GRAPH  $G$  which may have only straight EDGES, denoted  $\bar{\nu}(G)$ . For a COMPLETE GRAPH of order  $n \geq 10$ , the rectilinear crossing number is always larger than the general graph crossing number. The first few values for COMPLETE GRAPHS are 0, 0, 0, 0, 1, 3, 9, 19, 36, 61 or 62, ... (Sloane's A014540). The  $n = 10$  lower limit is from Singer (1986), who proved that

$$\bar{\nu}(K_n) \leq \frac{1}{312}(5n^4 - 39n^3 + 91n^2 - 57n). \quad (4)$$

Jensen (1971) has shown that

$$\bar{\nu}(K_n) \leq \frac{7}{432}n^4 + \mathcal{O}(n^3). \quad (5)$$

Consider the crossing number for a toroidal GRAPH. For a COMPLETE GRAPH, the first few are 0, 0, 0, 0, 0, 0, 0, 4, 9, 23, 42, 70, 105, 154, 226, 326, ... (Sloane's A014543). The toroidal crossing numbers for a COMPLETE BIGRAPH are given in the following table.

	1	2	3	4	5	6	7
1	0	0	0	0	0	0	
2		0	0	0	0	0	
3			0	0	0	0	
4					2		
5					5	8	
6						12	
7

**Cruciform**

A plane curve also called the CROSS CURVE and POLICEMAN ON POINT DUTY CURVE (Cundy and Rollett 1989). It is given by the equation

$$x^2 y^2 - a^2 x^2 - a^2 y^2 = 0, \quad (1)$$

which is equivalent to

$$1 - \frac{a^2}{y^2} - \frac{a^2}{x^2} = 0 \quad (2)$$

$$\frac{a^2}{x^2} + \frac{b^2}{y^2} = 1, \quad (3)$$

or, rewriting,

$$y^2 = \frac{a^2 x^2}{x^2 - a^2}. \quad (4)$$

In parametric form,

$$x = a \sec t \quad (5)$$

$$y = b \csc t. \quad (6)$$

The CURVATURE is

$$\kappa = \frac{3ab \csc^2 t \sec^2 t}{(b^2 \cos^2 t \csc^2 t + a^2 \sec^2 t \tan^2 t)^{3/2}}. \quad (7)$$

**Crystallography Restriction**

If a discrete GROUP of displacements in the plane has more than one center of rotation, then the only rotations that can occur are by 2, 3, 4, and 6. This can be shown as follows. It must be true that the sum of the interior angles divided by the number of sides is a divisor of  $360^\circ$ .

$$\frac{180^\circ(n-2)}{n} = \frac{360^\circ}{m},$$

where  $m$  is an INTEGER. Therefore, symmetry will be possible only for

$$\frac{2n}{n-2} = m,$$

where  $m$  is an INTEGER. This will hold for 1-, 2-, 3-, 4-, and 6-fold symmetry. That it does not hold for  $n > 6$  is seen by noting that  $n = 6$  corresponds to  $m = 3$ . The  $m = 2$  case requires that  $n = n - 2$  (impossible), and the  $m = 1$  case requires that  $n = -2$  (also impossible).

### Császár Polyhedron

A POLYHEDRON topologically equivalent to a TORUS discovered in the late 1940s. It has 7 VERTICES, 14 faces, and 21 EDGES, and is the DUAL POLYHEDRON of the SZILASSI POLYHEDRON. Its SKELETON is ISOMORPHIC to the COMPLETE GRAPH  $K_7$ .

see HYPERBOLIC COSECANT

### Cube

The three-dimensional PLATONIC SOLID ( $P_3$ ) which is also called the HEXAHEDRON. The cube is composed of six SQUARE faces  $6\{4\}$  which meet each other at RIGHT ANGLES, and has 8 VERTICES and 12 EDGES. It is described by the SCHLÄFLI SYMBOL  $\{4,3\}$ . It is a ZONOHEDRON. It is also the UNIFORM POLYHEDRON  $U_6$  with WYTHOFF SYMBOL  $3|24$ . It has the  $O_h$  OCTAHEDRAL GROUP of symmetries. The DUAL POLYHEDRON of the cube is the OCTAHEDRON.

Because the VOLUME of a cube of side length  $n$  is given by  $n^3$ , a number of the form  $n^3$  is called a CUBIC NUMBER (or sometimes simply "a cube"). Similarly, the operation of taking a number to the third POWER is called CUBING.

The cube cannot be STELLATED. A PLANE passing through the MIDPOINTS of opposite sides (perpendicular to a  $C_3$  axis) cuts the cube in a regular HEXAGONAL CROSS-SECTION (Gardner 1960; Steinhaus 1983, p. 170; Cundy and Rollett 1989, p. 157; Holden 1991, pp. 22–23). Since there are four such axes, there are four possibly hexagonal cross-sections. If the vertices of the cube are  $(\pm 1, \pm 1, \pm 1)$ , then the vertices of the inscribed HEXAGON are  $(0, -1, -1)$ ,  $(1, 0, -1)$ ,  $(1, 1, 0)$ ,  $(0, 1, 1)$ ,  $(-1, 0, 1)$ , and  $(-1, -1, 0)$ . The largest SQUARE which will fit inside a cube of side  $a$  has each corner a distance  $1/4$  from a corner of a cube. The resulting SQUARE has side length  $3\sqrt{2}a/4$ , and the cube containing that side is called PRINCE RUPERT'S CUBE.

The solid formed by the faces having the sides of the STELLA OCTANGULA (left figure) as DIAGONALS is a cube (right figure; Ball and Coxeter 1987).

The VERTICES of a cube of side length 2 with face-centered axes are given by  $(\pm 1, \pm 1, \pm 1)$ . If the cube is oriented with a space diagonal along the  $z$ -axis, the coordinates are  $(0, 0, \sqrt{3})$ ,  $(0, 2\sqrt{2}/3, 1/\sqrt{3})$ ,  $(\sqrt{2}, \sqrt{2}/3, -1/\sqrt{3})$ ,  $(\sqrt{2}, -\sqrt{2}/3, 1/\sqrt{3})$ ,  $(0, -2\sqrt{2}/3, -1/\sqrt{3})$ ,  $(-\sqrt{2}, -\sqrt{2}/3, 1/\sqrt{3})$ ,  $(-\sqrt{2}, \sqrt{2}/3, -1/\sqrt{3})$ , and the negatives of these vectors. A FACETED version is the GREAT CUBICUBOCTAHEDRON.

A cube of side length 1 has INRADIUS, MIDRADIUS, and CIRCUMRADIUS of

$$r = \frac{1}{2} = 0.5 \quad (1)$$

$$\rho = \frac{1}{2}\sqrt{2} \approx 0.70710 \quad (2)$$

$$R = \frac{1}{2}\sqrt{3} \approx 0.86602. \quad (3)$$

The cube has a DIHEDRAL ANGLE of

$$\alpha = \frac{1}{2}\pi. \quad (4)$$

The SURFACE AREA and VOLUME of the cube are

$$S = 6a^2 \quad (5)$$

$$V = a^3. \quad (6)$$

### Cube 2-Compound

A POLYHEDRON COMPOUND obtained by allowing two CUBES to share opposite VERTICES, then rotating one a sixth of a turn (Holden 1971, p. 34).

see also CUBE, CUBE 3-COMPOUND, CUBE 4-COMPOUND, CUBE 5-COMPOUND, POLYHEDRON COMPOUND

#### References

- Holden, A. *Shapes, Space, and Symmetry*. New York: Dover, 1991.

### Cube 3-Compound

A compound with the symmetry of the CUBE which arises by joining three CUBES such that each shares two  $C_2$  axes (Holden 1971, p. 35).

see also CUBE, CUBE 2-COMPOUND, CUBE 4-COMPOUND, CUBE 5-COMPOUND, POLYHEDRON COMPOUND

#### References

- Holden, A. *Shapes, Space, and Symmetry*. New York: Dover, 1991.

### Cube 4-Compound

A compound with the symmetry of the CUBE which arises by joining four CUBES such that each  $C_3$  axis falls along the  $C_3$  axis of one of the other CUBES (Holden 1971, p. 35).

see also CUBE, CUBE 2-COMPOUND, CUBE 3-COMPOUND, CUBE 5-COMPOUND, POLYHEDRON COMPOUND

#### References

- Holden, A. *Shapes, Space, and Symmetry*. New York: Dover, 1991.

### Cube 5-Compound

A POLYHEDRON COMPOUND consisting of the arrangement of five CUBES in the VERTICES of a DODECAHEDRON. In the above figure, let  $a$  be the length of a CUBE EDGE. Then

$$\begin{aligned} x &= \frac{1}{2}a(3 - \sqrt{5}) \\ \theta &= \tan^{-1} \left( \frac{3 - \sqrt{5}}{2} \right) \approx 20^\circ 54' \\ \phi &= \tan^{-1} \left( \frac{\sqrt{5} - 1}{2} \right) \approx 31^\circ 43' \\ \psi &= 90^\circ - \phi \approx 58^\circ 17' \\ \alpha &= 90^\circ - \theta \approx 69^\circ 6'. \end{aligned}$$

The compound is most easily constructed using pieces like the ones in the above line diagram. The cube 5-compound has the 30 facial planes of the RHOMBIC TRIACONTAHEDRON (Ball and Coxeter 1987).

see also CUBE, CUBE 2-COMPOUND, CUBE 3-COMPOUND, CUBE 4-COMPOUND, DODECAHEDRON,

POLYHEDRON COMPOUND, RHOMBIC TRIACONTAHE-  
DRON

### Cube Dissection

A CUBE can be divided into  $n$  subcubes for only  $n = 1, 8, 15, 20, 22, 27, 29, 34, 36, 38, 39, 41, 43, 45, 46$ , and  $n \geq 48$  (Sloane's A014544).

The seven pieces used to construct the  $3 \times 3 \times 3$  cube dissection known as the SOMA CUBE are one 3-POLYCUBE and six 4-POLYCUBES ( $1 \cdot 3 + 6 \cdot 4 = 27$ ), illustrated above.

Another  $3 \times 3 \times 3$  cube dissection due to Steinhaus uses three 5-POLYCUBES and three 4-POLYCUBES ( $3 \cdot 5 + 3 \cdot 4 = 27$ ), illustrated above.

It is possible to cut a  $1 \times 3$  RECTANGLE into two identical pieces which will form a CUBE (without overlapping) when folded and joined. In fact, an INFINITE number of solutions to this problem were discovered by C. L. Baker (Hunter and Madachy 1975).

### Cube Duplication

Also called the DELIAN PROBLEM or DUPLICATION OF THE CUBE. A classical problem of antiquity which, given the EDGE of a CUBE, requires a second CUBE to be constructed having double the VOLUME of the first using only a STRAIGHTEDGE and COMPASS.

Under these restrictions, the problem cannot be solved because the DELIAN CONSTANT  $2^{1/3}$  (the required RATIO of sides of the original CUBE and that to be constructed) is not a EUCLIDEAN NUMBER. The problem can be solved, however, using a NEUSIS CONSTRUCTION.

see also ALHAZEN'S BILLIARD PROBLEM, COMPASS, CUBE, DELIAN CONSTANT, GEOMETRIC PROBLEMS OF ANTIQUITY, NEUSIS CONSTRUCTION, STRAIGHTEDGE

## Cube-Octahedron Compound

A POLYHEDRON COMPOUND composed of a CUBE and its DUAL POLYHEDRON, the OCTAHEDRON. The 14 vertices are given by  $(\pm 1, \pm 1, \pm 1)$ ,  $(\pm 2, 0, 0)$ ,  $(0, \pm 2, 0)$ ,  $(0, 0, \pm 2)$ .

The solid common to both the CUBE and OCTAHEDRON (left figure) in a cube-octahedron compound is a CUBOCTAHEDRON (middle figure). The edges intersecting in the points plotted above are the diagonals of RHOMBUSES, and the 12 RHOMBUSES form a RHOMBIC DO-DECAHEDRON (right figure; Ball and Coxeter 1987).

## Cube Point Picking

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Let two points be picked randomly from a unit  $n$ -D HYPERCUBE. The expected distance between the points  $\Delta(N)$  is then

$$\begin{aligned}\Delta(1) &= \frac{1}{3} \\ \Delta(2) &= \frac{1}{15}[\sqrt{2} + 2 + 5 \ln(1 + \sqrt{2})] = 0.521405433 \dots \\ \Delta(3) &= \frac{1}{105}[4 + 17\sqrt{2} - 6\sqrt{3} + 21 \ln(1 + \sqrt{2}) \\ &\quad + 42 \ln(2 + \sqrt{3}) - 7\pi] = 0.661707182 \dots \\ \Delta(4) &= 0.77766 \dots \\ \Delta(5) &= 0.87852 \dots\end{aligned}$$

$$\Delta(6) = 0.96895 \dots$$

$$\Delta(7) = 1.05159 \dots$$

$$\Delta(8) = 1.12817 \dots$$

The function  $\Delta(n)$  satisfies

$$\frac{1}{3}n^{1/2} \leq \Delta(n) \leq (\frac{1}{6}n)^{1/2} \sqrt{\frac{1}{3} \left[ 1 + 2 \left( 1 - \frac{3}{5n} \right)^{1/2} \right]}$$

(Anderssen *et al.* 1976).

Pick  $N$  points  $p_1, \dots, p_N$  randomly in a unit  $n$ -cube. Let  $C$  be the CONVEX HULL, so

$$C \equiv \left\{ \sum_{j=1}^N \lambda_j p_j : \lambda_j \geq 0 \text{ for all } j \text{ and } \sum_{j=1}^N \lambda_j = 1 \right\}.$$

Let  $V(n, N)$  be the expected  $n$ -D VOLUME (the CONTENT) of  $C$ ,  $S(n, N)$  be the expected  $(n-1)$ -D SURFACE AREA of  $C$ , and  $P(n, N)$  the expected number of VERTICES on the POLYGONAL boundary of  $C$ . Then

$$\begin{aligned}\lim_{N \rightarrow \infty} \frac{N[1 - V(2, N)]}{\ln N} &= \frac{8}{3} \\ \lim_{N \rightarrow \infty} \sqrt{N}[4 - S(2, N)] &= \sqrt{2\pi} \left[ 2 - \int_0^1 (\sqrt{1+t^2} - 1)t^{-3/2} dt \right] \\ &= 4.2472965 \dots,\end{aligned}$$

and

$$\begin{aligned}\lim_{N \rightarrow \infty} P(2, N) - \frac{8}{3} \ln N &= \frac{8}{3}(\gamma - \ln 2) \\ &= -0.309150708 \dots\end{aligned}$$

(Rényi and Sulanke 1963, 1964). The average DISTANCE between two points chosen at random inside a unit cube is

$$\frac{1}{105}(4 + 17\sqrt{2} - 6\sqrt{3} + 21 \ln(1 + \sqrt{2}) + 42 \ln(2 + \sqrt{3}) - 7\pi)$$

(Robbins 1978, Le Lionnais 1983).

Pick  $n$  points on a CUBE, and space them as far apart as possible. The best value known for the minimum straight LINE distance between any two points is given in the following table.

$n$	$d(n)$
5	1.1180339887498
6	1.0606601482100
7	1
8	1
9	0.86602540378463
10	0.74999998333331
11	0.70961617562351
12	0.70710678118660
13	0.70710678118660
14	0.70710678118660
15	0.625

### Cube Power

A number raised to the third POWER.  $x^3$  is read as "x cubed."

see also CUBIC NUMBER

### Cube Root

Given a number  $z$ , the cube root of  $z$ , denoted  $\sqrt[3]{z}$  or  $z^{1/3}$  ( $z$  to the 1/3 POWER), is a number  $a$  such that  $a^3 = z$ . There are three (not necessarily distinct) cube roots for any number.

For real arguments, the cube root is an INCREASING FUNCTION, although the usual derivative test cannot be used to establish this fact at the ORIGIN since the derivative approaches infinity there (as illustrated above).

### Cube Triangle Picking

Pick 3 points at random in the unit  $n$ -HYPERCUBE. Denote the probability that the three points form an OBTUSE TRIANGLE  $\Pi(n)$ . Langford (1969) proved

$$\Pi(2) = \frac{97}{150} + \frac{1}{40}\pi = 0.725206483 \dots$$

### Cubed

A number to the POWER 3 is said to be cubed, so that  $x^3$  is called "x cubed."

see also CUBE ROOT, SQUARED

### Cubefree

A number is said to be cubefree if its PRIME decomposition contains no tripled factors. All PRIMES are therefore trivially cubefree. The cubefree numbers are 1, 2, 3, 4, 5, 6, 7, 9, 10, 11, 12, 13, 14, 15, 17, ... (Sloane's A004709). The cubeful numbers (i.e., those that contain at least one cube) are 8, 16, 24, 27, 32, 40, 48, 54, ... (Sloane's A046099). The number of cubefree numbers less than 10, 100, 1000, ... are 9, 85, 833,

8319, 83190, 831910, ..., and their asymptotic density is  $1/\zeta(3) \approx 0.831907$ , where  $\zeta(n)$  is the RIEMANN ZETA FUNCTION.

### Cubic Curve

A cubic curve is an ALGEBRAIC CURVE of degree 3. An algebraic curve over a FIELD  $K$  is an equation  $f(X, Y) = 0$ , where  $f(X, Y)$  is a POLYNOMIAL in  $X$  and  $Y$  with COEFFICIENTS in  $K$ , and the degree of  $f$  is the MAXIMUM degree of each of its terms (MONOMIALS).

Newton showed that all cubics can be generated by the projection of the five divergent cubic parabolas. Newton's classification of cubic curves appeared in the chapter "Curves" in *Lexicon Technicum* by John Harris published in London in 1710. Newton also classified all cubics into 72 types, missing six of them. In addition, he showed that any cubic can be obtained by a suitable projection of the ELLIPTIC CURVE

$$y^2 = ax^3 + bx^2 + cx + d, \quad (1)$$

where the projection is a BIRATIONAL TRANSFORMATION, and the general cubic can also be written as

$$y^2 = x^3 + ax + b. \quad (2)$$

Newton's first class is equations of the form

$$xy^2 + ey = ax^3 + bx^2 + cx + d. \quad (3)$$

This is the hardest case and includes the SERPENTINE CURVE as one of the subcases. The third class was

$$ay^2 = x(x^2 - 2bx + c), \quad (4)$$

which is called NEWTON'S DIVERGING PARABOLAS. Newton's 66th curve was the TRIDENT OF NEWTON. Newton's classification of cubics was criticized by Euler because it lacked generality. Plücker later gave a more detailed classification with 219 types.

Pick a point  $P$ , and draw the tangent to the curve at  $P$ . Call the point where this tangent intersects the curve  $Q$ . Draw another tangent and call the point of intersection with the curve  $R$ . Every curve of third degree has the property that, with the areas in the above labeled figure,

$$B = 16A \quad (5)$$

(Honsberger 1991).

### Cubic Equation

A cubic equation is a POLYNOMIAL equation of degree three. Given a general cubic equation

$$z^3 + a_2z^2 + a_1z + a_0 = 0 \quad (1)$$

(the COEFFICIENT  $a_3$  of  $z^3$  may be taken as 1 without loss of generality by dividing the entire equation through by  $a_3$ ), first attempt to eliminate the  $a_2$  term by making a substitution of the form

$$z \equiv x - \lambda. \quad (2)$$

Then

$$(x - \lambda)^3 + a_2(x - \lambda)^2 + a_1(x - \lambda) + a_0 = 0 \quad (3)$$

$$(x^3 - 3\lambda x^2 + 3\lambda^2 x - \lambda^3) + a_2(x^2 - 2\lambda x + \lambda^2) + a_1(x - \lambda) + a_0 = 0 \quad (4)$$

$$x^3 + x^2(a_2 - 3\lambda) + x(a_1 - 2a_2\lambda + 3\lambda^2) + (a_0 - a_1\lambda + a_2\lambda^2 - \lambda^3) = 0. \quad (5)$$

The  $x^2$  is eliminated by letting  $\lambda = a_2/3$ , so

$$z \equiv x - \frac{1}{3}a_2. \quad (6)$$

Then

$$z^3 = (x - \frac{1}{3}a_2)^3 = x^3 - a_2x^2 + \frac{1}{3}a_2^2x - \frac{1}{27}a_2^3 \quad (7)$$

$$a_2z^2 = a_2(x - \frac{1}{3}a_2)^2 = a_2x^2 - \frac{2}{3}a_2^2x + \frac{1}{9}a_2^3 \quad (8)$$

$$a_1z = a_1(x - \frac{1}{3}a_2) = a_1x - \frac{1}{3}a_1a_2, \quad (9)$$

so equation (1) becomes

$$x^3 + (-a_2 + a_2)x^2 + (\frac{1}{3}a_2^2 - \frac{2}{3}a_2^2 + a_1)x - (\frac{1}{27}a_2^3 - \frac{1}{9}a_2^3 + \frac{1}{3}a_1a_2 - a_0) = 0 \quad (10)$$

$$x^3 + (a_1 - \frac{1}{3}a_2^2)x - (\frac{1}{3}a_1a_2 - \frac{2}{27}a_2^3 - a_0) = 0 \quad (11)$$

$$x^3 + 3 \cdot \frac{3a_1 - a_2^2}{9}x - 2 \cdot \frac{9a_1a_2 - 27a_0 - 2a_2^3}{54} = 0. \quad (12)$$

Defining

$$p \equiv \frac{3a_1 - a_2^2}{3} \quad (13)$$

$$q \equiv \frac{9a_1a_2 - 27a_0 - 2a_2^3}{27} \quad (14)$$

then allows (12) to be written in the standard form

$$x^3 + px = q. \quad (15)$$

The simplest way to proceed is to make VIETA'S SUBSTITUTION

$$x = w - \frac{p}{3w}, \quad (16)$$

which reduces the cubic to the equation

$$w^3 - \frac{p^3}{27w^3} - q = 0, \quad (17)$$

which is easily turned into a QUADRATIC EQUATION in  $w^3$  by multiplying through by  $w^3$  to obtain

$$(w^3)^2 - q(w^3) - \frac{1}{27}p^3 = 0 \quad (18)$$

(Birkhoff and Mac Lane 1965, p. 106). The result from the QUADRATIC EQUATION is

$$\begin{aligned} w^3 &= \frac{1}{2} \left( q \pm \sqrt{q^2 + \frac{4}{27}p^3} \right) = \frac{1}{2}q \pm \sqrt{\frac{1}{4}q^2 + \frac{1}{27}p^3} \\ &= R \pm \sqrt{R^2 + Q^3}, \end{aligned} \quad (19)$$

where  $Q$  and  $R$  are sometimes more useful to deal with than are  $p$  and  $q$ . There are therefore six solutions for  $w$  (two corresponding to each sign for each ROOT of  $w^3$ ). Plugging  $w$  back in to (17) gives three pairs of solutions, but each pair is equal, so there are three solutions to the cubic equation.

Equation (12) may also be explicitly factored by attempting to pull out a term of the form  $(x - B)$  from the cubic equation, leaving behind a quadratic equation which can then be factored using the QUADRATIC FORMULA. This process is equivalent to making Vieta's substitution, but does a slightly better job of motivating Vieta's "magic" substitution, and also at producing the explicit formulas for the solutions. First, define the intermediate variables

$$Q \equiv \frac{3a_1 - a_2^2}{9} \quad (20)$$

$$R \equiv \frac{9a_1a_2 - 27a_0 - 2a_2^3}{54} \quad (21)$$

(which are identical to  $p$  and  $q$  up to a constant factor). The general cubic equation (12) then becomes

$$x^3 + 3Qx - 2R = 0. \quad (22)$$

Let  $B$  and  $C$  be, for the moment, arbitrary constants. An identity satisfied by PERFECT CUBIC equations is that

$$x^3 - B^3 = (x - B)(x^2 + Bx + B^2). \quad (23)$$

The general cubic would therefore be directly factorable if it did not have an  $x$  term (i.e., if  $Q = 0$ ). However, since in general  $Q \neq 0$ , add a multiple of  $(x - B)$ —say  $C(x - B)$ —to both sides of (23) to give the slightly messy identity

$$(x^3 - B^3) + C(x - B) = (x - B)(x^2 + Bx + B^2 + C) = 0, \quad (24)$$

which, after regrouping terms, is

$$x^3 + Cx - (B^3 + BC) = (x - B)[x^2 + Bx + (B^2 + C)] = 0. \quad (25)$$

We would now like to match the COEFFICIENTS  $C$  and  $-(B^3 + BC)$  with those of equation (22), so we must have

$$C = 3Q \quad (26)$$

$$B^3 + BC = 2R. \quad (27)$$

Plugging the former into the latter then gives

$$B^3 + 3QB = 2R. \quad (28)$$

Therefore, if we can find a value of  $B$  satisfying the above identity, we have factored a linear term from the cubic, thus reducing it to a QUADRATIC EQUATION. The trial solution accomplishing this miracle turns out to be the symmetrical expression

$$B = [R + \sqrt{Q^3 + R^2}]^{1/3} + [R - \sqrt{Q^3 + R^2}]^{1/3}. \quad (29)$$

Taking the second and third POWERS of  $B$  gives

$$\begin{aligned} B^2 &= [R + \sqrt{Q^3 + R^2}]^{2/3} + 2[R^2 - (Q^3 + R^2)]^{1/3} \\ &\quad + [R - \sqrt{Q^3 + R^2}]^{2/3} \\ &= [R + \sqrt{Q^3 + R^2}]^{2/3} + [R - \sqrt{Q^3 + R^2}]^{2/3} - 2Q \end{aligned} \quad (30)$$

$$\begin{aligned} B^3 &= -2QB + \left\{ [R + \sqrt{Q^3 + R^2}]^{1/3} + [R - \sqrt{Q^3 + R^2}]^{1/3} \right\} \\ &\quad \times \left\{ [R + \sqrt{Q^3 + R^2}]^{2/3} + [R - \sqrt{Q^3 + R^2}]^{2/3} \right\} \\ &= [R + \sqrt{Q^3 + R^2}] + [R - \sqrt{Q^3 + R^2}] \\ &\quad + [R - \sqrt{Q^3 + R^2}]^{1/3}[R - \sqrt{Q^3 + R^2}]^{2/3} \\ &\quad + [R - \sqrt{Q^3 + R^2}]^{2/3}[R - \sqrt{Q^3 + R^2}]^{1/3} - 2QB \\ &= -2QB + 2R + [R^2 - (Q^3 + R^2)]^{1/3} \\ &\quad \times \left[ \left( R + \sqrt{Q^3 + R^2} \right)^{1/3} + \left( R - \sqrt{Q^3 + R^2} \right)^{1/3} \right] \\ &= -2QB + 2R - QB = -3QB + 2R. \end{aligned} \quad (31)$$

Plugging  $B^3$  and  $B$  into the left side of (28) gives

$$(-3QB + 2R) + 3QB = 2R, \quad (32)$$

so we have indeed found the factor  $(x - B)$  of (22), and we need now only factor the quadratic part. Plugging  $C = 3Q$  into the quadratic part of (25) and solving the resulting

$$x^2 + Bx + (B^2 + 3Q) = 0 \quad (33)$$

then gives the solutions

$$\begin{aligned} x &= \frac{1}{2}[-B \pm \sqrt{B^2 - 4(B^2 + 3Q)}] \\ &= -\frac{1}{2}B \pm \frac{1}{2}\sqrt{-3B^2 - 12Q} \\ &= -\frac{1}{2}B \pm \frac{1}{2}\sqrt{3}i\sqrt{B^2 + 4Q}. \end{aligned} \quad (34)$$

These can be simplified by defining

$$\begin{aligned} A &\equiv [R + \sqrt{Q^3 + R^2}]^{1/3} - [R - \sqrt{Q^3 + R^2}]^{1/3} \quad (35) \\ A^2 &= [R + \sqrt{Q^3 + R^2}]^{2/3} - 2[R^2 - (Q^3 + R^2)]^{1/3} \\ &\quad + [R - \sqrt{Q^3 + R^2}]^{2/3} \\ &= [R + \sqrt{Q^3 + R^2}]^{2/3} + [R - \sqrt{Q^3 + R^2}]^{2/3} + 2Q \\ &= B^2 + 4Q, \end{aligned} \quad (36)$$

so that the solutions to the quadratic part can be written

$$x = -\frac{1}{2}B \pm \frac{1}{2}\sqrt{3}iA. \quad (37)$$

Defining

$$D \equiv Q^3 + R^2 \quad (38)$$

$$S \equiv \sqrt[3]{R + \sqrt{D}} \quad (39)$$

$$T \equiv \sqrt[3]{R - \sqrt{D}}, \quad (40)$$

where  $D$  is the DISCRIMINANT (which is defined slightly differently, including the opposite SIGN, by Birkhoff and Mac Lane 1965) then gives very simple expressions for  $A$  and  $B$ , namely

$$B = S + T \quad (41)$$

$$A = S - T. \quad (42)$$

Therefore, at last, the ROOTS of the original equation in  $z$  are then given by

$$z_1 = -\frac{1}{3}a_2 + (S + T) \quad (43)$$

$$z_2 = -\frac{1}{3}a_2 - \frac{1}{2}(S + T) + \frac{1}{2}i\sqrt{3}(S - T) \quad (44)$$

$$z_3 = -\frac{1}{3}a_2 - \frac{1}{2}(S + T) - \frac{1}{2}i\sqrt{3}(S - T), \quad (45)$$

with  $a_2$  the COEFFICIENT of  $z^2$  in the original equation, and  $S$  and  $T$  as defined above. These three equations

giving the three ROOTS of the cubic equation are sometimes known as CARDANO'S FORMULA. Note that if the equation is in the standard form of Vieta

$$x^3 + px = q, \quad (46)$$

in the variable  $x$ , then  $a_2 = 0$ ,  $a_1 = p$ , and  $a_0 = -q$ , and the intermediate variables have the simple form (c.f. Beyer 1987)

$$Q = \frac{1}{3}p \quad (47)$$

$$R = \frac{1}{2}q \quad (48)$$

$$D \equiv Q^3 + R^2 = \left(\frac{p}{3}\right)^3 + \left(\frac{q}{2}\right)^2. \quad (49)$$

The equation for  $z_1$  in CARDANO'S FORMULA does not have an  $i$  appearing in it explicitly while  $z_2$  and  $z_3$  do, but this does not say anything about the number of REAL and COMPLEX ROOTS (since  $S$  and  $T$  are themselves, in general, COMPLEX). However, determining which ROOTS are REAL and which are COMPLEX can be accomplished by noting that if the DISCRIMINANT  $D > 0$ , one ROOT is REAL and two are COMPLEX CONJUGATES; if  $D = 0$ , all ROOTS are REAL and at least two are equal; and if  $D < 0$ , all ROOTS are REAL and unequal. If  $D < 0$ , define

$$\theta \equiv \cos^{-1} \left( \frac{R}{\sqrt{-Q^3}} \right). \quad (50)$$

Then the REAL solutions are of the form

$$z_1 = 2\sqrt{-Q} \cos \left( \frac{\theta}{3} \right) - \frac{1}{3}a_2 \quad (51)$$

$$z_2 = 2\sqrt{-Q} \cos \left( \frac{\theta + 2\pi}{3} \right) - \frac{1}{3}a_2 \quad (52)$$

$$z_3 = 2\sqrt{-Q} \cos \left( \frac{\theta + 4\pi}{3} \right) - \frac{1}{3}a_2. \quad (53)$$

This procedure can be generalized to find the REAL ROOTS for any equation in the standard form (46) by using the identity

$$\sin^3 \theta - \frac{3}{4} \sin \theta + \frac{1}{4} \sin(3\theta) = 0 \quad (54)$$

(Dickson 1914) and setting

$$x \equiv \sqrt{\frac{4|p|}{3}} y \quad (55)$$

(Birkhoff and Mac Lane 1965, pp. 90-91), then

$$\left( \frac{4|p|}{3} \right)^{3/2} y^3 + p \sqrt{\frac{4|p|}{3}} y = q \quad (56)$$

$$y^3 + \frac{3}{4} \frac{p}{|p|} y = \left( \frac{3}{4|p|} \right)^{3/2} q \quad (57)$$

$$4y^3 + 3 \operatorname{sgn}(p)y = \frac{1}{2}q \left( \frac{3}{|p|} \right)^{3/2} \equiv C. \quad (58)$$

If  $p > 0$ , then use

$$\sinh(3\theta) = 4 \sinh^3 \theta + 3 \sinh \theta \quad (59)$$

to obtain

$$y = \sinh\left(\frac{1}{3} \sinh^{-1} C\right). \quad (60)$$

If  $p < 0$  and  $|C| \geq 1$ , use

$$\cosh(3\theta) = 4 \cosh^3 \theta - 3 \cosh \theta, \quad (61)$$

and if  $p < 0$  and  $|C| \leq 1$ , use

$$\cos(3\theta) = 4 \cos^3 \theta - 3 \cos \theta, \quad (62)$$

to obtain

$$y = \begin{cases} \cosh\left(\frac{1}{3} \cosh^{-1} C\right) & \text{for } C \geq 1 \\ -\cosh\left(\frac{1}{3} \cosh^{-1} |C|\right) & \text{for } C \leq -1 \\ \cos\left(\frac{1}{3} \cos^{-1} C\right) \text{ [three solutions]} & \text{for } |C| < 1. \end{cases} \quad (63)$$

The solutions to the original equation are then

$$x_i = 2\sqrt{\frac{|p|}{3}} y_i - \frac{1}{3}a_2. \quad (64)$$

An alternate approach to solving the cubic equation is to use LAGRANGE RESOLVENTS. Let  $\omega \equiv e^{2\pi i/3}$ , define

$$(1, x_1) = x_1 + x_2 + x_3 \quad (65)$$

$$(\omega, x_1) = x_1 + \omega x_2 + \omega^2 x_3 \quad (66)$$

$$(\omega^2, x_1) = x_1 + \omega^2 x_2 + \omega x_3, \quad (67)$$

where  $x_i$  are the ROOTS of

$$x^3 + px + q = 0, \quad (68)$$

and consider the equation

$$[x - (u_1 + u_2)][x - (\omega u_1 + \omega^2 u_2)][x - (\omega^2 u_1 + \omega u_2)] = 0, \quad (69)$$

where  $u_1$  and  $u_2$  are COMPLEX NUMBERS. The ROOTS are then

$$x_j = \omega^j u_1 + \omega^{2j} u_2 \quad (70)$$

for  $j = 0, 1, 2$ . Multiplying through gives

$$x^3 - 3u_1 u_2 x - (u_1^3 + u_2^3) = 0, \quad (71)$$

or

$$x^3 + px + q = 0, \quad (72)$$

where

$$u_1^3 + u_2^3 = -q \quad (73)$$

$$u_1^3 u_2^3 = -\left(\frac{1}{3}\right)^3. \quad (74)$$

The solutions satisfy NEWTON'S IDENTITIES

$$z_1 + z_2 + z_3 = -a_2 \quad (75)$$

$$z_1 z_2 + z_2 z_3 + z_1 z_3 = a_1 \quad (76)$$

$$z_1 z_2 z_3 = -a_0. \quad (77)$$

In standard form,  $a_2 = 0$ ,  $a_1 = p$ , and  $a_0 = -q$ , so we have the identities

$$p = z_1 z_2 - z_3^2 \quad (78)$$

$$(z_1 - z_2)^2 = -(4p - 3z_3^2) \quad (79)$$

$$z_1^2 + z_2^2 + z_3^2 = -2p. \quad (80)$$

Some curious identities involving the roots of a cubic equation due to Ramanujan are given by Berndt (1994).

Cubic Number

A FIGURATE NUMBER of the form  $n^3$ , for  $n$  a POSITIVE INTEGER. The first few are 1, 8, 27, 64, ... (Sloane's A000578). The GENERATING FUNCTION giving the cubic numbers is

$$\frac{x(x^2 + 4x + 1)}{(x - 1)^4} = x + 8x^2 + 27x^3 + \dots \quad (1)$$

The HEX PYRAMIDAL NUMBERS are equivalent to the cubic numbers (Conway and Guy 1996).

The number of *positive* cubes needed to represent the numbers 1, 2, 3, ... are 1, 2, 3, 4, 5, 6, 7, 1, 2, 3, 4, 5, 6, 7, 8, 2, ... (Sloane's A02376), and the number of distinct ways to represent the numbers 1, 2, 3, ... in terms of positive cubes are 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, 3, 4, 4, 4, 5, 5, 5, 5, ... (Sloane's A003108). In the early twentieth century, Dickson, Pillai, and Niven proved that every POSITIVE INTEGER is the sum of not more than nine CUBES (so  $g(3) = 9$  in WARING'S PROBLEM).

In 1939, Dickson proved that the only INTEGERS requiring nine CUBES are 23 and 239. Wieferich proved that only 15 INTEGERS require eight CUBES: 15, 22, 50, 114, 167, 175, 186, 212, 213, 238, 303, 364, 420, 428, and 454 (Sloane's A018889). The quantity  $G(3)$  in WARING'S PROBLEM therefore satisfies  $G(3) \leq 7$ , and the largest number known requiring seven cubes is 8042. The following table gives the first few numbers which require at least  $N = 1, 2, 3, \dots, 9$  (positive) cubes to represent them as a sum.

$N$	Sloane	Numbers
1	000578	1, 8, 27, 64, 125, 216, 343, 512, ...
2	003325	2, 9, 16, 28, 35, 54, 65, 72, 91, ...
3	003072	3, 10, 17, 24, 29, 36, 43, 55, 62, ...
4	003327	4, 11, 18, 25, 30, 32, 37, 44, 51, ...
5	003328	5, 12, 19, 26, 31, 33, 38, 40, 45, ...
6		6, 13, 20, 34, 39, 41, 46, 48, 53, ...
7	018890	7, 14, 21, 42, 47, 49, 61, 77, ...
8	018889	15, 22, 50, 114, 167, 175, 186, ...,
9	—	23, 239

There is a finite set of numbers which cannot be expressed as the sum of *distinct* cubes: 2, 3, 4, 5, 6, 7, 10,

11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, ... (Sloane's A001476). The following table gives the numbers which can be represented in  $W$  different ways as a sum of  $N$  positive cubes. For example,

$$157 = 4^3 + 4^3 + 3^3 + 1^3 + 1^3 = 5^3 + 2^3 + 2^3 + 2^3 + 2^3 \quad (2)$$

can be represented in  $W = 2$  ways by  $N = 5$  cubes. The smallest number representable in  $W = 2$  ways as a sum of  $N = 2$  cubes,

$$1729 = 1^3 + 12^3 = 9^3 + 10^3, \quad (3)$$

is called the HARDY-RAMANUJAN NUMBER and has special significance in the history of mathematics as a result of a story told by Hardy about Ramanujan. Sloane's A001235 is defined as the sequence of numbers which are the sum of cubes in two *or more* ways, and so appears identical in the first few terms.

$N$	$W$	Sloane	Numbers
1	1	000578	1, 8, 27, 64, 125, 216, 343, 512, ...
2	1	025403	2, 9, 16, 28, 35, 54, 65, 72, 91, ...
2	2		1729, 4104, 13832, 20683, 32832, ...
2	3	003825	87539319, 119824488, 143604279, ...
2	4	003826	6963472309248, 12625136269928, ...
2	5		48988659276962496, ...
2	6		8230545258248091551205888, ...
3	1	025395	3, 10, 17, 24, 29, 36, 43, 55, 62, ...

It is believed to be possible to express any number as a SUM of four (positive or negative) cubes, although this has not been proved for numbers of the form  $9n \pm 4$ . In fact, all numbers *not* of the form  $9n \pm 4$  are known to be expressible as the SUM of *three* (positive or negative) cubes except 30, 33, 42, 52, 74, 110, 114, 156, 165, 195, 290, 318, 366, 390, 420, 435, 444, 452, 462, 478, 501, 530, 534, 564, 579, 588, 600, 606, 609, 618, 627, 633, 732, 735, 758, 767, 786, 789, 795, 830, 834, 861, 894, 903, 906, 912, 921, 933, 948, 964, 969, and 975 (Guy 1994, p. 151).

The following table gives the possible residues (mod  $n$ ) for cubic numbers for  $n = 1$  to 20, as well as the number of distinct residues  $s(n)$ .

$n$	$s(n)$	$x^3 \pmod n$
2	2	0, 1
3	3	0, 1, 2
4	3	0, 1, 3
5	5	0, 1, 2, 3, 4
6	6	0, 1, 2, 3, 4, 5
7	3	0, 1, 6
8	5	0, 1, 3, 5, 7
9	3	0, 1, 8
10	10	0, 1, 2, 3, 4, 5, 6, 7, 8, 9
11	11	0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10
12	9	0, 1, 3, 4, 5, 7, 8, 9, 11
13	5	0, 1, 5, 8, 12
14	6	0, 1, 6, 7, 8, 13
15	15	0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14
16	10	0, 1, 3, 5, 7, 8, 9, 11, 13, 15
17	17	0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16
18	6	0, 1, 8, 9, 10, 17
19	7	0, 1, 7, 8, 11, 12, 18
20	15	0, 1, 3, 4, 5, 7, 8, 9, 11, 12, 13, 15, 16, 17, 19

Dudeney found two RATIONAL NUMBERS other than 1 and 2 whose cubes sum to 9,

$$\frac{415280564497}{348671682660} \text{ and } \frac{676702467503}{348671682660} \quad (4)$$

The problem of finding two RATIONAL NUMBERS whose cubes sum to six was "proved" impossible by Legendre. However, Dudeney found the simple solutions 17/21 and 37/21.

The only three consecutive INTEGERS whose cubes sum to a cube are given by the DIOPHANTINE EQUATION

$$3^3 + 4^3 + 5^3 = 6^3. \quad (5)$$

CATALAN'S CONJECTURE states that 8 and 9 ( $2^3$  and  $3^2$ ) are the only consecutive POWERS (excluding 0 and 1), i.e., the only solution to CATALAN'S DIOPHANTINE PROBLEM. This CONJECTURE has not yet been proved or refuted, although R. Tijdeman has proved that there can be only a finite number of exceptions should the CONJECTURE not hold. It is also known that 8 and 9 are the only consecutive cubic and SQUARE NUMBERS (in either order).

There are six POSITIVE INTEGERS equal to the sum of the DIGITS of their cubes: 1, 8, 17, 18, 26, and 27 (Moret Blanc 1879). There are four POSITIVE INTEGERS equal to the sums of the cubes of their digits:

$$153 = 1^3 + 5^3 + 3^3 \quad (6)$$

$$370 = 3^3 + 7^3 + 0^3 \quad (7)$$

$$371 = 3^3 + 7^3 + 1^3 \quad (8)$$

$$407 = 4^3 + 0^3 + 7^3 \quad (9)$$

(Ball and Coxeter 1987). There are two SQUARE NUMBERS of the form  $n^3 - 4$ :  $4 = 2^3 - 4$  and  $121 = 5^3 - 4$  (Le Lionnais 1983). A cube cannot be the concatenation of two cubes, since if  $c^3$  is the concatenation of  $a^3$  and  $b^3$ ,

then  $c^3 = 10^k a^3 + b^3$ , where  $k$  is the number of digits in  $b^3$ . After shifting any powers of 1000 in  $10^k$  into  $a^3$ , the original problem is equivalent to finding a solution to one of the DIOPHANTINE EQUATIONS

$$c^3 - b^3 = a^3 \quad (10)$$

$$c^3 - b^3 = 10a^3 \quad (11)$$

$$c^3 - b^3 = 100a^3. \quad (12)$$

None of these have solutions in integers, as proved independently by Sylvester, Lucas, and Pepin (Dickson 1966, pp. 572–578).

#### Cubic Reciprocity Theorem

A RECIPROCITY THEOREM for the case  $n = 3$  solved by Gauss using "INTEGERS" of the form  $a + b\rho$ , when  $\rho$  is a root of  $x^2 + x + 1 = 0$  and  $a, b$  are INTEGERS.

### Cubic Surface

An ALGEBRAIC SURFACE of ORDER 3. Schläfli and Cayley classified the singular cubic surfaces. On the general cubic, there exists a curious geometrical structure called DOUBLE SIXES, and also a particular arrangement of 27 (possibly complex) lines, as discovered by Schläfli (Salmon 1965, Fischer 1986) and sometimes called SOLOMON'S SEAL LINES. A nonregular cubic surface can contain 3, 7, 15, or 27 real lines (Segre 1942, Le Lionnais 1983). The CLEBSCH DIAGONAL CUBIC contains all possible 27. The maximum number of ORDINARY DOUBLE POINTS on a cubic surface is four, and the unique cubic surface having four ORDINARY DOUBLE POINTS is the CAYLEY CUBIC.

Schoutte (1910) showed that the 27 lines can be put into a ONE-TO-ONE correspondence with the vertices of a particular POLYTOPE in 6-D space in such a manner that all incidence relations between the lines are mirrored in the connectivity of the POLYTOPE and conversely (Du Val 1931). A similar correspondence can be made between the 28 bitangents of the general plane QUARTIC CURVE and a 7-D POLYTOPE (Coxeter 1928) and between the tritangent planes of the canonical curve of genus 4 and an 8-D POLYTOPE (Du Val 1933).

A smooth cubic surface contains 45 TRITANGENTS (Hunt). The Hessian of smooth cubic surface contains at least 10 ORDINARY DOUBLE POINTS, although the Hessian of the CAYLEY CUBIC contains 14 (Hunt).

### Cubitruncated Cuboctahedron

The UNIFORM POLYHEDRON  $U_{16}$  whose DUAL is the TETRADYAKIS HEXAHEDRON. It has WYTHOFF SYMBOL  $3 \frac{4}{3} 4$ . Its faces are  $8\{6\} + 6\{8\} + 6\{\frac{8}{3}\}$ . It is a FACETED OCTAHEDRON. The CIRCUMRADIUS for a cubitruncated cuboctahedron of unit edge length is

$$R = \frac{1}{2}\sqrt{7}.$$

### References

### Cuboctahedron

An ARCHIMEDEAN SOLID (also called the DYMAXION or HEPTAPARALLELOHEDRON) whose DUAL is the RHOMBIC DODECAHEDRON. It is one of the two convex QUASIREGULAR POLYHEDRA and has SCHLÄFLI SYMBOL  $\{3\}_4$ . It is also UNIFORM POLYHEDRON  $U_7$  and has WYTHOFF SYMBOL  $2|34$ . Its faces are  $\{3\} + 6\{4\}$ . It has the  $O_h$  OCTAHEDRAL GROUP of symmetries.

The VERTICES of a cuboctahedron with EDGE length of  $\sqrt{2}$  are  $(0, \pm 1, \pm 1)$ ,  $(\pm 1, 0, \pm 1)$ , and  $(\pm 1, \pm 1, 0)$ . The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for  $a = 1$  are

$$\begin{aligned} r &= \frac{3}{4} = 0.75 \\ \rho &= \frac{1}{2}\sqrt{3} \approx 0.86602 \\ R &= 1. \end{aligned}$$

FACETED versions include the CUBOHEMIOCTAHEDRON and OCTAHEMIOCTAHEDRON.

The solid common to both the CUBE and OCTAHEDRON (left figure) in a CUBE-OCTAHEDRON COMPOUND is a CUBOCTAHEDRON (right figure; Ball and Coxeter 1987). *see also* ARCHIMEDEAN SOLID, CUBE, CUBE-OCTAHEDRON COMPOUND, CUBOHEMIOCTAHEDRON, OCTAHEDRON, OCTAHEMIOCTAHEDRON, QUASIREGULAR POLYHEDRON, RHOMBIC DODECAHEDRON, RHOMBUS

### Cullen Number

A number of the form

$$C_n = 2^n n + 1.$$

The first few are 3, 9, 25, 65, 161, 385, ... (Sloane's A002064). The only Cullen numbers  $C_n$  for  $n < 300,000$  which are PRIME are for  $n = 1, 141, 4713, 5795, 6611, 18496, 32292, 32469, 59656, 90825, 262419, \dots$  (Sloane's A005849; Ballinger). Cullen numbers are DIVISIBLE by  $p = 2n - 1$  if  $p$  is a PRIME of the form  $8k \pm 3$ .

### Cumulant

Let  $\phi(t)$  be the CHARACTERISTIC FUNCTION, defined as the FOURIER TRANSFORM of the PROBABILITY DENSITY FUNCTION,

$$\phi(t) = \mathcal{F}[P(x)] = \int_{-\infty}^{\infty} e^{itx} P(x) dx. \quad (1)$$

Then the cumulants  $\kappa_n$  are defined by

$$\ln \phi(t) \equiv \sum_{n=0}^{\infty} \kappa_n \frac{(it)^n}{n!}. \quad (2)$$

Taking the MACLAURIN SERIES gives

$$\begin{aligned} \ln \phi(t) &= (it)\mu'_1 + \frac{1}{2}(it)^2(\mu'_2 - \mu_1'^2) \\ &+ \frac{1}{3!}(it)^3(2\mu_1'^3 - 3\mu_1'\mu_2' + \mu_3') \\ &+ \frac{1}{4!}(it)^4(-6\mu_1'^4 + 12\mu_1'^2\mu_2' - 3\mu_2'^2 - 4\mu_1'\mu_3' + \mu_4') \\ &+ \frac{1}{5!}(it)^5[-24\mu_1'^5 + 60\mu_1'^3\mu_2' + 20\mu_1'^2\mu_3' + 10\mu_2'\mu_3' \\ &+ 5\mu_1'(6\mu_2'^2 - \mu_4') + \mu_5'] + \dots, \quad (3) \end{aligned}$$

where  $\mu'_n$  are MOMENTS about 0, so

$$\kappa_1 = \mu'_1 \quad (4)$$

$$\kappa_2 = \mu'_2 - \mu'^2_1 \quad (5)$$

$$\kappa_3 = 2\mu'^3_1 - 3\mu'_1\mu'_2 + \mu'_3 \quad (6)$$

$$\kappa_4 = -6\mu'^4_1 + 12\mu'^2_1\mu'_2 - 3\mu'^2_2 - 4\mu'_1\mu'_3 + \mu'_4 \quad (7)$$

$$\kappa_5 = -24\mu'^5_1 + 60\mu'^3_1\mu'_2 + 20\mu'^2_1\mu'_3 + 10\mu'_2\mu'_3 + 5\mu'_1(6\mu'^2_2 - \mu'_4) + \mu'_5. \quad (8)$$

In terms of the MOMENTS  $\mu_n$  about the MEAN,

$$\kappa_1 = \mu \quad (9)$$

$$\kappa_2 = \mu_2 = \sigma^2 \quad (10)$$

$$\kappa_3 = \mu_3 \quad (11)$$

$$\kappa_4 = \mu_4 - 3\mu_2^2 \quad (12)$$

$$\kappa_5 = \mu_5 - 10\mu_2\mu_3, \quad (13)$$

where  $\mu$  is the MEAN and  $\sigma^2 \equiv \mu_2$  is the VARIANCE.

The  $k$ -STATISTICS are UNBIASED ESTIMATORS of the cumulants.

#### Cumulant-Generating Function

Let  $M(h)$  be the MOMENT-GENERATING FUNCTION. Then

$$K(h) \equiv \ln M(h) = \kappa_1 h + \frac{1}{2!} h^2 \kappa_2 + \frac{1}{3!} h^3 \kappa_3 + \dots$$

If

$$L = \sum_{j=1}^M c_j x_j$$

is a function of  $N$  independent variables, the cumulant generating function for  $L$  is then

$$K(h) = \sum_{j=1}^N K_j(c_j h).$$

#### Cunningham Chain

A SEQUENCE of PRIMES  $q_1 < q_2 < \dots < q_k$  is a Cunningham chain of the first kind (second kind) of length  $k$  if  $q_{i+1} = 2q_i + 1$  ( $q_{i+1} = 2q_i - 1$ ) for  $i = 1, \dots, k-1$ . Cunningham PRIMES of the first kind are SOPHIE GERMAIN PRIMES.

The two largest known Cunningham chains (of the first kind) of length three are  $(384205437 \cdot 2^{4000} - 1, 384205437 \cdot 2^{4001} - 1, 384205437 \cdot 2^{4002} - 1)$  and  $(651358155 \cdot 2^{3291} - 1, 651358155 \cdot 2^{3292} - 1, 651358155 \cdot 2^{3293} - 1)$ , both discovered by W. Roonguthai in 1998.

### Cunningham Function

Sometimes also called the PEARSON-CUNNINGHAM FUNCTION. It can be expressed using WHITTAKER FUNCTIONS (Whittaker and Watson 1990, p. 353).

$$\omega_{n,m}(x) \equiv \frac{e^{\pi i(m/2-n)+x}}{\Gamma(1+n-\frac{1}{2}m)} U(\frac{1}{2}m-n, 1+m, x),$$

where  $U$  is a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND (Abramowitz and Stegun 1972, p. 510).

see also CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND, WHITTAKER FUNCTION

#### References

### Cunningham Number

A BINOMIAL NUMBER of the form  $C^\pm(b, n) \equiv b^n \pm 1$ . Bases  $b^k$  which are themselves powers need not be considered since they correspond to  $(b^k)^n \pm 1 = b^{kn} \pm 1$ . PRIME NUMBERS of the form  $C^\pm(b, n)$  are very rare.

A NECESSARY (but not SUFFICIENT) condition for  $C^+(2, n) = 2^n + 1$  to be PRIME is that  $n$  be of the form  $n = 2^m$ . Numbers of the form  $F_m = C^+(2, 2^m) = 2^{2^m} + 1$  are called FERMAT NUMBERS, and the only known PRIMES occur for  $C^+(2, 1) = 3$ ,  $C^+(2, 2) = 5$ ,  $C^+(2, 4) = 17$ ,  $C^+(2, 8) = 257$ , and  $C^+(2, 16) = 65537$  (i.e.,  $n = 0, 1, 2, 3, 4$ ). The only other PRIMES  $C^+(b, n)$  for nontrivial  $b \leq 11$  and  $2 \leq n \leq 1000$  are  $C^+(6, 2) = 37$ ,  $C^+(6, 4) = 1297$ , and  $C^+(10, 2) = 101$ .

PRIMES of the form  $C^-(b, n)$  are also very rare. The MERSENNE NUMBERS  $M_n = C^-(2, n) = 2^n - 1$  are known to be prime only for 37 values, the first few of which are  $n = 2, 3, 5, 7, 13, 17, 19, \dots$  (Sloane's A000043). There are no other PRIMES  $C^-(b, n)$  for nontrivial  $b \leq 20$  and  $2 \leq n \leq 1000$ .

In 1925, Cunningham and Woodall (1925) gathered together all that was known about the PRIMALITY and factorization of the numbers  $C^\pm(b, n)$  and published a small book of tables. These tables collected from scattered sources the known prime factors for the bases 2 and 10 and also presented the authors' results of 30 years' work with these and other bases.

Since 1925, many people have worked on filling in these tables. D. H. Lehmer, a well-known mathematician who died in 1991, was for many years a leader of these efforts. Lehmer was a mathematician who was at the forefront of computing as modern electronic computers became a reality. He was also known as the inventor of some

ingenious pre-electronic computing devices specifically designed for factoring numbers.

Updated factorizations were published in Brillhart *et al.* (1988). The current archive of Cunningham number factorizations for  $b = 1, \dots, \pm 12$  is kept on <ftp://sable.ox.ac.uk/pub/math/cunningham>. The tables have been extended by Brent and te Riele (1992) to  $b = 13, \dots, 100$  with  $m < 255$  for  $b < 30$  and  $m < 100$  for  $b \geq 30$ . All numbers with exponent 58 and smaller, and all composites with  $\leq 90$  digits have now been factored.

### Cunningham Project

see CUNNINGHAM NUMBER

### Cupola

An  $n$ -gonal cupola  $Q_n$  (possible for only  $n = 3, 4, 5$ ) is a POLYHEDRON having  $n$  TRIANGULAR and  $n$  SQUARE faces separating an  $\{n\}$  and a  $\{2n\}$  REGULAR POLYGON. The coordinates of the base VERTICES are

$$\left( R \cos \left[ \frac{\pi(2k+1)}{2n} \right], R \sin \left[ \frac{\pi(2k+1)}{2n} \right], 0 \right), \quad (1)$$

and the coordinates of the top VERTICES are

$$\left( r \cos \left[ \frac{2k\pi}{n} \right], r \sin \left[ \frac{2k\pi}{n} \right], z \right), \quad (2)$$

where  $R$  and  $r$  are the CIRCUMRADII of the base and top

$$R = \frac{1}{2}a \csc\left(\frac{\pi}{2n}\right) \quad (3)$$

$$r = \frac{1}{2}a \csc\left(\frac{\pi}{n}\right), \quad (4)$$

and  $z$  is the height, obtained by letting  $k = 0$  in the equations (1) and (2) to obtain the coordinates of neighboring bottom and top VERTICES,

$$\mathbf{b} = \begin{bmatrix} R \cos\left(\frac{\pi}{2n}\right) \\ R \sin\left(\frac{\pi}{2n}\right) \\ 0 \end{bmatrix} \quad (5)$$

$$\mathbf{t} = \begin{bmatrix} r \\ 0 \\ z \end{bmatrix}. \quad (6)$$

Since all side lengths are  $a$ ,

$$|\mathbf{b} - \mathbf{t}|^2 = a^2. \quad (7)$$

Solving for  $z$  then gives

$$\left[R \cos\left(\frac{\pi}{2n}\right) - r\right]^2 + R^2 \sin^2\left(\frac{\pi}{2n}\right) + z^2 = a^2 \quad (8)$$

$$z^2 + R^2 + r^2 - 2rR \cos\left(\frac{\pi}{2n}\right) = a^2 \quad (9)$$

$$\begin{aligned} z &= \sqrt{a^2 - 2rR \cos\left(\frac{\pi}{2n}\right) - r^2 - R^2} \\ &= a \sqrt{1 - \frac{1}{4} \csc^2\left(\frac{\pi}{n}\right)}. \end{aligned} \quad (10)$$

#### Cupolarotunda

A CUPOLA adjoined to a ROTUNDA.

see also GYROCUPOLAROTUNDA, ORTHOCUPOLAROTUNDA

#### Curl

The curl of a TENSOR field is given by

$$(\nabla \times A)^\alpha = \epsilon^{\alpha\mu\nu} A_{\nu;\mu}, \quad (1)$$

where  $\epsilon_{ijk}$  is the LEVI-CIVITA TENSOR and " ; " is the COVARIANT DERIVATIVE. For a VECTOR FIELD, the curl is denoted

$$\text{curl}(\mathbf{F}) \equiv \nabla \times \mathbf{F}, \quad (2)$$

and  $\nabla \times \mathbf{F}$  is normal to the PLANE in which the "circulation" is MAXIMUM. Its magnitude is the limiting value of circulation per unit AREA,

$$(\nabla \times \mathbf{F}) \cdot \hat{\mathbf{n}} \equiv \lim_{A \rightarrow 0} \frac{\oint_C \mathbf{F} \cdot d\mathbf{s}}{A}. \quad (3)$$

Let

$$\mathbf{F} \equiv F_1 \hat{\mathbf{u}}_1 + F_2 \hat{\mathbf{u}}_2 + F_3 \hat{\mathbf{u}}_3 \quad (4)$$

and

$$h_i \equiv \left| \frac{\partial \mathbf{r}}{\partial u_i} \right|, \quad (5)$$

then

$$\begin{aligned} \nabla \times \mathbf{F} &\equiv \frac{1}{h_1 h_2 h_3} \begin{vmatrix} h_1 \hat{\mathbf{u}}_1 & h_2 \hat{\mathbf{u}}_2 & h_3 \hat{\mathbf{u}}_3 \\ \frac{\partial}{\partial u_1} & \frac{\partial}{\partial u_2} & \frac{\partial}{\partial u_3} \\ h_1 F_1 & h_2 F_2 & h_3 F_3 \end{vmatrix} \\ &= \frac{1}{h_2 h_3} \left[ \frac{\partial}{\partial u_2} (h_3 F_3) - \frac{\partial}{\partial u_3} (h_2 F_2) \right] \hat{\mathbf{u}}_1 \\ &\quad + \frac{1}{h_1 h_3} \left[ \frac{\partial}{\partial u_3} (h_1 F_1) - \frac{\partial}{\partial u_1} (h_3 F_3) \right] \hat{\mathbf{u}}_2 \\ &\quad + \frac{1}{h_1 h_2} \left[ \frac{\partial}{\partial u_1} (h_2 F_2) - \frac{\partial}{\partial u_2} (h_1 F_1) \right] \hat{\mathbf{u}}_3. \end{aligned} \quad (6)$$

Special cases of the curl formulas above can be given for CURVILINEAR COORDINATES.

see also CURL THEOREM, DIVERGENCE, GRADIENT, VECTOR DERIVATIVE

#### References

Arfken, G. "Curl,  $\nabla \times$ ." §1.8 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 42-47, 1985.

#### Curl Theorem

A special case of STOKES' THEOREM in which  $F$  is a VECTOR FIELD and  $M$  is an oriented, compact embedded 2-MANIFOLD with boundary in  $\mathbb{R}^3$ , given by

$$\int_S (\nabla \times \mathbf{F}) \cdot d\mathbf{a} = \int_{\partial S} \mathbf{F} \cdot d\mathbf{s}. \quad (1)$$

There are also alternate forms. If

$$\mathbf{F} \equiv \mathbf{c}F, \quad (2)$$

then

$$\int_S d\mathbf{a} \times \nabla F = \int_C F d\mathbf{s}. \quad (3)$$

and if

$$\mathbf{F} \equiv \mathbf{c} \times \mathbf{P}, \quad (4)$$

then

$$\int_S (d\mathbf{a} \times \nabla) \times \mathbf{P} = \int_C d\mathbf{s} \times \mathbf{P}. \quad (5)$$

see also CHANGE OF VARIABLES THEOREM, CURL, STOKES' THEOREM

**Curlicue Fractal**

The curlicue fractal is a figure obtained by the following procedure. Let  $s$  be an IRRATIONAL NUMBER. Begin with a line segment of unit length, which makes an ANGLE  $\phi_0 \equiv 0$  to the horizontal. Then define  $\theta_n$  iteratively by

$$\theta_{n+1} = (\theta_n + 2\pi s) \pmod{2\pi},$$

with  $\theta_0 = 0$ . To the end of the previous line segment, draw a line segment of unit length which makes an angle

$$\phi_{n+1} = \theta_n + \phi_n \pmod{2\pi},$$

to the horizontal (Pickover 1995). The result is a FRAC-TAL, and the above figures correspond to the curlicue fractals with 10,000 points for the GOLDEN RATIO  $\phi$ ,  $\ln 2$ ,  $e$ ,  $\sqrt{2}$ , the EULER-MASCHERONI CONSTANT  $\gamma$ ,  $\pi$ , and FEIGENBAUM CONSTANT  $\delta$ .

The TEMPERATURE of these curves is given in the following table.

Constant	Temperature
golden ratio $\phi$	46
$\ln 2$	51
$e$	58
$\sqrt{2}$	58
Euler-Mascheroni constant $\gamma$	63
$\pi$	90
Feigenbaum constant $\delta$	92

**Curtate Cycloid Evolute**

The EVOLUTE of the CURTATE CYCLOID

$$x = a\phi - b \sin \phi \quad (1)$$

$$y = a - b \cos \phi. \quad (2)$$

is given by

$$x = \frac{a[-2b\phi + 2a\phi \cos \phi - 2a \sin \phi + b \sin(2\phi)]}{2(a \cos \phi - b)} \quad (3)$$

$$y = \frac{a(a - b \cos \phi)^2}{b(a \cos \phi - b)}. \quad (4)$$

### Curvature

In general, there are two important types of curvature: **EXTRINSIC CURVATURE** and **INTRINSIC CURVATURE**. The **EXTRINSIC CURVATURE** of curves in 2- and 3-space was the first type of curvature to be studied historically, culminating in the **FRENET FORMULAS**, which describe a **SPACE CURVE** entirely in terms of its “curvature,” **TORSION**, and the initial starting point and direction.

After the curvature of 2- and 3-D curves was studied, attention turned to the curvature of surfaces in 3-space. The main curvatures which emerged from this scrutiny are the **MEAN CURVATURE**, **GAUSSIAN CURVATURE**, and the **WEINGARTEN MAP**. **MEAN CURVATURE** was the most important for applications at the time and was the most studied, but Gauss was the first to recognize the importance of the **GAUSSIAN CURVATURE**.

Because **GAUSSIAN CURVATURE** is “intrinsic,” it is detectable to 2-dimensional “inhabitants” of the surface, whereas **MEAN CURVATURE** and the **WEINGARTEN MAP** are not detectable to someone who can’t study the 3-dimensional space surrounding the surface on which he resides. The importance of **GAUSSIAN CURVATURE** to an inhabitant is that it controls the surface **AREA** of **SPHERES** around the inhabitant.

Riemann and many others generalized the concept of curvature to **SECTIONAL CURVATURE**, **SCALAR CURVATURE**, the **RIEMANN TENSOR**, **RICCI CURVATURE**, and a host of other **INTRINSIC** and **EXTRINSIC CURVATURES**. General curvatures no longer need to be numbers, and can take the form of a **MAP**, **GROUP**, **GROUPOID**, tensor field, etc.

The simplest form of curvature and that usually first encountered in **CALCULUS** is an **EXTRINSIC CURVATURE**. In 2-D, let a **PLANE CURVE** be given by **CARTESIAN** parametric equations  $x = x(t)$  and  $y = y(t)$ . Then the curvature  $\kappa$  is defined by

$$\kappa \equiv \frac{d\phi}{ds} = \frac{\frac{d\phi}{dt}}{\frac{ds}{dt}} = \frac{\frac{d\phi}{dt}}{\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}} = \frac{\frac{d\phi}{dt}}{\sqrt{x'^2 + y'^2}}, \quad (1)$$

where  $\phi$  is the **POLAR ANGLE** and  $s$  is the **ARC LENGTH**. As can readily be seen from the definition, curvature therefore has units of inverse distance. The  $d\phi/dt$  derivative in the above equation can be eliminated by using the identity

$$\tan \phi = \frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{y'}{x'}, \quad (2)$$

so

$$\frac{d}{dt}(\tan \phi) = \sec^2 \phi \frac{d\phi}{dt} = \frac{x'y'' - y'x''}{x'^2} \quad (3)$$

and

$$\begin{aligned} \frac{d\phi}{dt} &= \frac{1}{1 + \tan^2 \phi} \frac{x'y'' - y'x''}{x'^2} \\ &= \frac{1}{\frac{y'^2}{x'^2}} \frac{x'y'' - y'x''}{x'^2} = \frac{x'y'' - y'x''}{x'^2 + y'^2}. \end{aligned} \quad (4)$$

Combining (2) and (4) gives

$$\kappa = \frac{x'y'' - y'x''}{(x'^2 + y'^2)^{3/2}}. \quad (5)$$

For a 2-D curve written in the form  $y = f(x)$ , the equation of curvature becomes

$$\kappa = \frac{\frac{d^2y}{dx^2}}{\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2}}. \quad (6)$$

If the 2-D curve is instead parameterized in **POLAR COORDINATES**, then

$$\kappa = \frac{r^2 + 2r_\theta^2 - rr_{\theta\theta}}{(r^2 + r_\theta^2)^{3/2}}, \quad (7)$$

where  $r_\theta \equiv \partial r / \partial \theta$  (Gray 1993). In **PEDAL COORDINATES**, the curvature is given by

$$\kappa = \frac{1}{r} \frac{dp}{dr}. \quad (8)$$

The curvature for a 2-D curve given implicitly by  $g(x, y) = 0$  is given by

$$\kappa = \frac{g_{xx}g_y^2 - 2g_{xy}g_xg_y + g_{yy}g_x^2}{(g_x^2 + g_y^2)^{3/2}} \quad (9)$$

(Gray 1993).

Now consider a parameterized **SPACE CURVE**  $\mathbf{r}(t)$  in 3-D for which the **TANGENT VECTOR**  $\hat{\mathbf{T}}$  is defined as

$$\hat{\mathbf{T}} \equiv \frac{\frac{d\mathbf{r}}{dt}}{\left|\frac{d\mathbf{r}}{dt}\right|} = \frac{\frac{d\mathbf{r}}{dt}}{\frac{ds}{dt}}. \quad (10)$$

Therefore,

$$\frac{d\mathbf{r}}{dt} = \frac{ds}{dt} \hat{\mathbf{T}} \quad (11)$$

$$\frac{d^2\mathbf{r}}{dt^2} = \frac{d^2s}{dt^2} \hat{\mathbf{T}} + \frac{ds}{dt} \frac{d\hat{\mathbf{T}}}{dt} = \frac{ds^2}{dt^2} \hat{\mathbf{T}} + \kappa \hat{\mathbf{N}} \left(\frac{ds}{dt}\right)^2, \quad (12)$$

where  $\hat{\mathbf{N}}$  is the **NORMAL VECTOR**. But

$$\begin{aligned} \frac{d\mathbf{r}}{dt} \times \frac{d^2\mathbf{r}}{dt^2} &= \frac{ds}{dt} \frac{d^2s}{dt^2} (\hat{\mathbf{T}} \times \hat{\mathbf{T}}) + \kappa \left(\frac{ds}{dt}\right)^3 (\hat{\mathbf{T}} \times \hat{\mathbf{N}}) \\ &= \kappa \left(\frac{ds}{dt}\right)^3 (\hat{\mathbf{T}} \times \hat{\mathbf{N}}) \end{aligned} \quad (13)$$

$$\left| \frac{d\mathbf{r}}{dt} \times \frac{d^2\mathbf{r}}{dt^2} \right| = \kappa \left( \frac{ds}{dt} \right)^3 = \kappa \left| \frac{d\mathbf{r}}{dt} \right|^3, \quad (14)$$

so

$$\kappa = \left| \frac{d\hat{\mathbf{T}}}{ds} \right| = \frac{\left| \frac{d\mathbf{r}}{dt} \times \frac{d^2\mathbf{r}}{dt^2} \right|}{\left| \frac{d\mathbf{r}}{dt} \right|^3}. \quad (15)$$

The curvature of a 2-D curve is related to the RADIUS OF CURVATURE of the curve's OSCULATING CIRCLE. Consider a CIRCLE specified parametrically by

$$x = a \cos t \quad (16)$$

$$y = a \sin t \quad (17)$$

which is tangent to the curve at a given point. The curvature is then

$$\kappa = \frac{x'y'' - y'x''}{(x'^2 + y'^2)^{3/2}} = \frac{a^2}{a^3} = \frac{1}{a}, \quad (18)$$

or one over the RADIUS OF CURVATURE. The curvature of a CIRCLE can also be repeated in vector notation. For the CIRCLE with  $0 \leq t < 2\pi$ , the ARC LENGTH is

$$\begin{aligned} s(t) &= \int_0^t \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\ &= \int_0^t \sqrt{a^2 \cos^2 t + a^2 \sin^2 t} dt = at, \end{aligned} \quad (19)$$

so  $t = s/a$  and the equations of the CIRCLE can be rewritten as

$$x = a \cos \left( \frac{s}{a} \right) \quad (20)$$

$$y = a \sin \left( \frac{s}{a} \right). \quad (21)$$

The POSITION VECTOR is then given by

$$\mathbf{r}(s) = a \cos \left( \frac{s}{a} \right) \hat{\mathbf{x}} + a \sin \left( \frac{s}{a} \right) \hat{\mathbf{y}}, \quad (22)$$

and the TANGENT VECTOR is

$$\hat{\mathbf{T}} = \frac{d\mathbf{r}}{ds} = -\sin \left( \frac{s}{a} \right) \hat{\mathbf{x}} + \cos \left( \frac{s}{a} \right) \hat{\mathbf{y}}, \quad (23)$$

so the curvature is related to the RADIUS OF CURVATURE  $a$  by

$$\begin{aligned} \kappa &= \left| \frac{d\hat{\mathbf{T}}}{ds} \right| = \left| -\frac{1}{a} \cos \left( \frac{s}{a} \right) \hat{\mathbf{x}} - \frac{1}{a} \sin \left( \frac{s}{a} \right) \hat{\mathbf{y}} \right| \\ &= \sqrt{\frac{\cos^2 \left( \frac{s}{a} \right) + \sin^2 \left( \frac{s}{a} \right)}{a^2}} = \frac{1}{a}, \end{aligned} \quad (24)$$

as expected.

Four very important derivative relations in differential geometry related to the FRENET FORMULAS are

$$\dot{\mathbf{r}} = \mathbf{T} \quad (25)$$

$$\ddot{\mathbf{r}} = \kappa \mathbf{N} \quad (26)$$

$$\ddot{\mathbf{r}} = \kappa \mathbf{N} + \kappa(\tau \mathbf{B} - \kappa \mathbf{T}) \quad (27)$$

$$[\dot{\mathbf{r}}, \ddot{\mathbf{r}}, \ddot{\mathbf{r}}] = \kappa^2 \tau, \quad (28)$$

where  $\mathbf{T}$  is the TANGENT VECTOR,  $\mathbf{N}$  is the NORMAL VECTOR,  $\mathbf{B}$  is the BINORMAL VECTOR, and  $\tau$  is the TORSION (Coxeter 1969, p. 322).

The curvature at a point on a surface takes on a variety of values as the PLANE through the normal varies. As  $\kappa$  varies, it achieves a minimum and a maximum (which are in perpendicular directions) known as the PRINCIPAL CURVATURES. As shown in Coxeter (1969, pp. 352–353),

$$\kappa^2 - \sum b_i^i \kappa + \det(b_i^j) = 0 \quad (29)$$

$$\kappa^2 - 2H\kappa + K = 0, \quad (30)$$

where  $K$  is the GAUSSIAN CURVATURE,  $H$  is the MEAN CURVATURE, and  $\det$  denotes the DETERMINANT.

The curvature  $\kappa$  is sometimes called the FIRST CURVATURE and the TORSION  $\tau$  the SECOND CURVATURE. In addition, a THIRD CURVATURE (sometimes called TOTAL CURVATURE)

$$\sqrt{ds_T^2 + ds_B^2} \quad (31)$$

is also defined. A signed version of the curvature of a CIRCLE appearing in the DESCARTES CIRCLE THEOREM for the radius of the fourth of four mutually tangent circles is called the BEND.

**Curvature Center**

The point on the POSITIVE RAY of the NORMAL VECTOR at a distance  $\rho(s)$ , where  $\rho$  is the RADIUS OF CURVATURE. It is given by

$$\mathbf{z} = \mathbf{x} + \rho \mathbf{N} = \mathbf{x} + \rho^2 \frac{\mathbf{T}}{ds}, \quad (1)$$

where  $\mathbf{N}$  is the NORMAL VECTOR and  $\mathbf{T}$  is the TANGENT VECTOR. It can be written in terms of  $\mathbf{x}$  explicitly as

$$\mathbf{z} = \mathbf{x} + \frac{\mathbf{x}''(\mathbf{x}' \cdot \mathbf{x}')^2 - \mathbf{x}'(\mathbf{x}' \cdot \mathbf{x}')(\mathbf{x}' \cdot \mathbf{x}'')}{(\mathbf{x}' \cdot \mathbf{x}')(\mathbf{x}'' \cdot \mathbf{x}'') - (\mathbf{x}' \cdot \mathbf{x}'')^2}. \quad (2)$$

For a CURVE represented parametrically by  $(f(t), g(t))$ ,

$$\alpha = f - \frac{(f'^2 - g'^2)g'}{f'g'' - f''g'} \quad (3)$$

$$\beta = g + \frac{(f'^2 - g'^2)f'}{f'g'' - f''g'}. \quad (4)$$

**Curvature Scalar**

The curvature scalar is given by

$$R \equiv g^{\mu\kappa} R_{\mu\kappa},$$

where  $g^{\mu\kappa}$  is the METRIC TENSOR and  $R_{\mu\kappa}$  is the RICCI TENSOR.

see also CURVATURE, GAUSSIAN CURVATURE, MEAN CURVATURE, METRIC TENSOR, RADIUS OF CURVATURE, RICCI TENSOR, RIEMANN-CHRISTOFFEL TENSOR

**Curvature Vector**

$$\mathbf{K} \equiv \frac{d\mathbf{T}}{ds},$$

where  $\mathbf{T}$  is the TANGENT VECTOR defined by

$$\mathbf{T} \equiv \frac{\frac{d\mathbf{x}}{ds}}{\left| \frac{d\mathbf{x}}{ds} \right|}.$$

**Curve**

A CONTINUOUS MAP from a 1-D SPACE to an  $n$ -D SPACE. Loosely speaking, the word "curve" is often used to mean the GRAPH of a 2- or 3-D curve. The simplest curves can be represented parametrically in  $n$ -D SPACE as

$$\begin{aligned} x_1 &= f_1(t) \\ x_2 &= f_2(t) \\ &\vdots \\ x_n &= f_n(t). \end{aligned}$$

Other simple curves can be simply defined only implicitly, i.e., in the form

$$f(x_1, x_2, \dots) = 0.$$

## Curve of Constant Breadth

see CURVE OF CONSTANT WIDTH

## Curve of Constant Precession

A curve whose CENTRODE revolves about a fixed axis with constant ANGLE and SPEED when the curve is traversed with unit SPEED. The TANGENT INDICATRIX of a curve of constant precession is a SPHERICAL HELIX. An ARC LENGTH parameterization of a curve of constant precession with NATURAL EQUATIONS

$$\kappa(s) = -\omega \sin(\mu s) \quad (1)$$

$$\tau(s) = \omega \cos(\mu s) \quad (2)$$

is

$$x(s) = \frac{\alpha + \mu \sin[(\alpha - \mu)s]}{2\alpha} - \frac{\alpha - \mu \sin[(\alpha + \mu)s]}{2\alpha} \quad (3)$$

$$y(s) = -\frac{\alpha + \mu \cos[(\alpha - \mu)s]}{2\alpha} + \frac{\alpha - \mu \cos[(\alpha + \mu)s]}{2\alpha} \quad (4)$$

$$z(s) = \frac{\omega}{\mu\alpha} \sin(\mu s), \quad (5)$$

where

$$\alpha \equiv \sqrt{\omega^2 + \mu^2} \quad (6)$$

and  $\omega$ , and  $\mu$  are constant. This curve lies on a circular one-sheeted HYPERBOLOID

$$x^2 + y^2 - \frac{\mu^2}{\omega^2} z^2 = \frac{4\mu^2}{\omega^4}. \quad (7)$$

The curve is closed IFF  $\mu/\alpha$  is RATIONAL.

## Curve of Constant Slope

see GENERALIZED HELIX

## Curve of Constant Width

Curves which, when rotated in a square, make contact with all four sides. The "width" of a closed convex curve is defined as the distance between parallel lines bounding it ("supporting lines"). Every curve of constant width is convex. Curves of constant width have the same "width" regardless of their orientation between the parallel lines. In fact, they also share the same PERIMETER (BARBIER'S THEOREM). Examples include the CIRCLE (with largest AREA), and REULEAUX TRIANGLE (with smallest AREA) but there are an infinite number. A curve of constant width can be used in a special drill chuck to cut square "HOLES."

A generalization gives solids of constant width. These do not have the same surface AREA for a given width, but their shadows are curves of constant width with the same width!

see also DELTA CURVE, KAKEYA NEEDLE PROBLEM, REULEAUX TRIANGLE

## Curvilinear Coordinates

A general METRIC  $g_{\mu\nu}$  has a LINE ELEMENT

$$ds^2 = g_{\mu\nu} du^\mu du^\nu, \quad (1)$$

where EINSTEIN SUMMATION is being used. Curvilinear coordinates are defined as those with a diagonal METRIC so that

$$g_{\mu\nu} \equiv \delta_\nu^\mu h_\mu^2, \quad (2)$$

where  $\delta_\nu^\mu$  is the KRONECKER DELTA. Curvilinear coordinates therefore have a simple LINE ELEMENT

$$ds^2 = \delta_\nu^\mu h_\mu^2 du^\mu du^\nu = h_\mu^2 du^{\mu^2}, \quad (3)$$

which is just the PYTHAGOREAN THEOREM, so the differential VECTOR is

$$d\mathbf{r} = h_\mu du_\mu \hat{\mathbf{u}}_\mu, \quad (4)$$

or

$$d\mathbf{r} = \frac{\partial \mathbf{r}}{\partial u_1} du_1 + \frac{\partial \mathbf{r}}{\partial u_2} du_2 + \frac{\partial \mathbf{r}}{\partial u_3} du_3, \quad (5)$$

where the SCALE FACTORS are

$$h_i = \left| \frac{\partial \mathbf{r}}{\partial u_i} \right| \quad (6)$$

and

$$\hat{\mathbf{u}}_i \equiv \frac{\frac{\partial \mathbf{r}}{\partial u_i}}{\left| \frac{\partial \mathbf{r}}{\partial u_i} \right|} = \frac{1}{h_i} \frac{\partial \mathbf{r}}{\partial u_i}. \quad (7)$$

Equation (5) may therefore be re-expressed as

$$d\mathbf{r} = h_1 du_1 \hat{\mathbf{u}}_1 + h_2 du_2 \hat{\mathbf{u}}_2 + h_3 du_3 \hat{\mathbf{u}}_3. \quad (8)$$

The GRADIENT is

$$\text{grad}(\phi) \equiv \nabla \phi = \frac{1}{h_1} \frac{\partial \phi}{\partial u_1} \hat{\mathbf{u}}_1 + \frac{1}{h_2} \frac{\partial \phi}{\partial u_2} \hat{\mathbf{u}}_2 + \frac{1}{h_3} \frac{\partial \phi}{\partial u_3} \hat{\mathbf{u}}_3, \quad (9)$$

the DIVERGENCE is

$$\text{div}(\mathbf{F}) \equiv \nabla \cdot \mathbf{F} \equiv \frac{1}{h_1 h_2 h_3} \left[ \frac{\partial}{\partial u_1} (h_2 h_3 F_1) + \frac{\partial}{\partial u_2} (h_3 h_1 F_2) + \frac{\partial}{\partial u_3} (h_1 h_2 F_3) \right], \quad (10)$$

and the CURL is

$$\begin{aligned} \nabla \times \mathbf{F} &\equiv \frac{1}{h_1 h_2 h_3} \begin{vmatrix} h_1 \hat{\mathbf{u}}_1 & h_2 \hat{\mathbf{u}}_2 & h_3 \hat{\mathbf{u}}_3 \\ \frac{\partial}{\partial u_1} & \frac{\partial}{\partial u_2} & \frac{\partial}{\partial u_3} \\ h_1 F_1 & h_2 F_2 & h_3 F_3 \end{vmatrix} \\ &= \frac{1}{h_2 h_3} \left[ \frac{\partial}{\partial u_2} (h_3 F_3) - \frac{\partial}{\partial u_3} (h_2 F_2) \right] \hat{\mathbf{u}}_1 \\ &\quad + \frac{1}{h_1 h_3} \left[ \frac{\partial}{\partial u_3} (h_1 F_1) - \frac{\partial}{\partial u_1} (h_3 F_3) \right] \hat{\mathbf{u}}_2 \\ &\quad + \frac{1}{h_1 h_2} \left[ \frac{\partial}{\partial u_1} (h_2 F_2) - \frac{\partial}{\partial u_2} (h_1 F_1) \right] \hat{\mathbf{u}}_3. \end{aligned} \quad (11)$$

Orthogonal curvilinear coordinates satisfy the additional constraint that

$$\hat{\mathbf{u}}_i \cdot \hat{\mathbf{u}}_j = \delta_{ij}. \quad (12)$$

Therefore, the LINE ELEMENT is

$$ds^2 = d\mathbf{r} \cdot d\mathbf{r} = h_1^2 du_1^2 + h_2^2 du_2^2 + h_3^2 du_3^2 \quad (13)$$

and the VOLUME ELEMENT is

$$\begin{aligned} dV &= |(h_1 \hat{\mathbf{u}}_1 du_1) \cdot (h_2 \hat{\mathbf{u}}_2 du_2) \times (h_3 \hat{\mathbf{u}}_3 du_3)| \\ &= h_1 h_2 h_3 du_1 du_2 du_3 \\ &= \left| \frac{\partial \mathbf{r}}{\partial u_1} \cdot \frac{\partial \mathbf{r}}{\partial u_2} \times \frac{\partial \mathbf{r}}{\partial u_3} \right| du_1 du_2 du_3 \\ &= \begin{vmatrix} \frac{\partial x}{\partial u_1} & \frac{\partial x}{\partial u_2} & \frac{\partial x}{\partial u_3} \\ \frac{\partial y}{\partial u_1} & \frac{\partial y}{\partial u_2} & \frac{\partial y}{\partial u_3} \\ \frac{\partial z}{\partial u_1} & \frac{\partial z}{\partial u_2} & \frac{\partial z}{\partial u_3} \end{vmatrix} du_1 du_2 du_3 \\ &= \left| \frac{\partial(x, y, z)}{\partial(u_1, u_2, u_3)} \right| du_1 du_2 du_3, \end{aligned} \quad (14)$$

where the latter is the JACOBIAN.

Orthogonal curvilinear coordinate systems include BIPOLAR CYLINDRICAL COORDINATES, BISPHERICAL COORDINATES, CARTESIAN COORDINATES, CONFOCAL ELLIPSOIDAL COORDINATES, CONFOCAL PARABOLOIDAL COORDINATES, CONICAL COORDINATES, CYCLIDIC COORDINATES, CYLINDRICAL COORDINATES, ELLIPSOIDAL COORDINATES, ELLIPTIC CYLINDRICAL COORDINATES, OBLATE SPHEROIDAL COORDINATES, PARABOLIC COORDINATES, PARABOLIC CYLINDRICAL COORDINATES, PARABOLOIDAL COORDINATES, POLAR COORDINATES, PROLATE SPHEROIDAL COORDINATES, SPHERICAL COORDINATES, and TOROIDAL COORDINATES. These are degenerate cases of the CONFOCAL ELLIPSOIDAL COORDINATES.

## Cusp

A function  $f(x)$  has a cusp (also called a SPINODE) at a point  $x_0$  if  $f(x)$  is CONTINUOUS at  $x_0$  and

$$\lim_{x \rightarrow x_0} f'(x) = \infty$$

from one side while

$$\lim_{x \rightarrow x_0} f'(x) = -\infty$$

from the other side, so the curve is CONTINUOUS but the DERIVATIVE is not. A cusp is a type of DOUBLE POINT. The above plot shows the curve  $x^3 - y^2 = 0$ , which has a cusp at the ORIGIN.

von Seggern, D. *CRC Standard Curves and Surfaces*. Boca Raton, FL: CRC Press, p. 28, 1993.

## Cusp Form

A cusp form on  $\Gamma_0(N)$ , the group of INTEGER matrices with determinant 1 which are upper triangular mod  $N$ , is an ANALYTIC FUNCTION on the upper half-plane consisting of the COMPLEX NUMBERS with POSITIVE IMAGINARY PART. Weight  $n$  cusp forms satisfy

$$f\left(\frac{az+b}{cz+d}\right) = (cz+d)^n f(z)$$

for all matrices

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \in \Gamma_0(N).$$

see also MODULAR FORM

## Cusp Map

The function

$$f(x) = 1 - 2|x|^{1/2}$$

for  $x \in [-1, 1]$ . The INVARIANT DENSITY is

$$\rho(y) = \frac{1}{2}(1 - y).$$

## CW-Approximation Theorem

If  $X$  is any SPACE, then there is a CW-COMPLEX  $Y$  and a MAP  $f : Y \rightarrow X$  inducing ISOMORPHISMS on all HOMOTOPY, HOMOLOGY, and COHOMOLOGY groups.

## CW-Complex

A CW-complex is a homotopy-theoretic generalization of the notion of a SIMPLICIAL COMPLEX. A CW-complex is any SPACE  $X$  which can be built by starting off with a discrete collection of points called  $X^0$ , then attaching 1-D DISKS  $D^1$  to  $X^0$  along their boundaries  $S^0$ , writing  $X^1$  for the object obtained by attaching the  $D^1$ s to  $X^0$ , then attaching 2-D DISKS  $D^2$  to  $X^1$  along their boundaries  $S^1$ , writing  $X^2$  for the new SPACE, and so on, giving spaces  $X^n$  for every  $n$ . A CW-complex is any SPACE that has this sort of decomposition into SUBSPACES  $X^n$  built up in such a hierarchical fashion (so the  $X^n$ s must exhaust all of  $X$ ). In particular,  $X^n$  may be built from  $X^{n-1}$  by attaching infinitely many  $n$ -DISKS, and the attaching MAPS  $S^{n-1} \rightarrow X^{n-1}$  may be any continuous MAPS.

The main importance of CW-complexes is that, for the sake of HOMOTOPY, HOMOLOGY, and COHOMOLOGY groups, every SPACE is a CW-complex. This is called the CW-APPROXIMATION THEOREM. Another is WHITEHEAD'S THEOREM, which says that MAPS between CW-complexes that induce ISOMORPHISMS on all HOMOTOPY GROUPS are actually HOMOTOPY equivalences.

see also COHOMOLOGY, CW-APPROXIMATION THEOREM, HOMOLOGY GROUP, HOMOTOPY GROUP, SIMPLICIAL COMPLEX, SPACE, SUBSPACE, WHITEHEAD'S THEOREM

### Cycle (Circle)

A CIRCLE with an arrow indicating a direction.

### Cycle (Graph)

A subset of the EDGE-set of a graph that forms a CHAIN (GRAPH), the first node of which is also the last (also called a CIRCUIT).

see also CYCLIC GRAPH, HAMILTONIAN CYCLE, WALK

### Cycle Graph

A cycle graph is a GRAPH which shows cycles of a GROUP as well as the connectivity between the cycles. Several examples are shown above. For  $Z_4$ , the group elements  $A_i$  satisfy  $A_i^4 = 1$ , where 1 is the IDENTITY ELEMENT, and two elements satisfy  $A_1^2 = A_3^2 = 1$ .

For a CYCLIC GROUP of COMPOSITE ORDER  $n$  (e.g.,  $Z_4$ ,  $Z_6$ ,  $Z_8$ ), the degenerate subcycles corresponding to factors dividing  $n$  are often not shown explicitly since their presence is implied.

see also CHARACTERISTIC FACTOR, CYCLIC GROUP

### References

Shanks, D. *Solved and Unsolved Problems in Number Theory*, 4th ed. New York: Chelsea, pp. 83–98, 1993.

### Cycle (Map)

An  $n$ -cycle is a finite sequence of points  $Y_0, \dots, Y_{n-1}$  such that, under a MAP  $G$ ,

$$Y_1 = G(Y_0)$$

$$Y_2 = G(Y_1)$$

$$Y_{n-1} = G(Y_{n-2})$$

$$Y_0 = G(Y_{n-1}).$$

In other words, it is a periodic trajectory which comes back to the same point after  $n$  iterations of the cycle. Every point  $Y_j$  of the cycle satisfies  $Y_j = G^n(Y_j)$  and is therefore a FIXED POINT of the mapping  $G^n$ . A fixed point of  $G$  is simply a CYCLE of period 1.

### Cycle (Permutation)

A SUBSET of a PERMUTATION whose elements trade places with one another. A cycle decomposition of a PERMUTATION can therefore be viewed as a CLASS of a PERMUTATION GROUP. For example, in the PERMUTATION GROUP  $\{4, 2, 1, 3\}$ ,  $\{1, 3, 4\}$  is a 3-cycle ( $1 \rightarrow 3, 3 \rightarrow 4$ , and  $4 \rightarrow 1$ ) and  $\{2\}$  is a 1-cycle ( $2 \rightarrow 2$ ). Every PERMUTATION GROUP on  $n$  symbols can be uniquely expressed as a product of disjoint cycles. The cyclic decomposition of a PERMUTATION can be computed in *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL) with the function `ToCycles` and the `PERMUTATION` corresponding to a cyclic decomposition can be computed with `FromCycles`. According to Vardi (1991), the *Mathematica* code for `ToCycles` is one of the most obscure ever written.

To find the number  $N(m, n)$  of  $m$  cycles in a PERMUTATION GROUP of order  $n$ , take

$$N(n, m) = (-1)^{n-m} S_1(n, m),$$

where  $S_1$  is the STIRLING NUMBER OF THE FIRST KIND.

### Cyclic Graph

A GRAPH of  $n$  nodes and  $n$  edges such that node  $i$  is connected to the two adjacent nodes  $i+1$  and  $i-1 \pmod{n}$ , where the nodes are numbered  $0, 1, \dots, n-1$ .

see also CYCLE (GRAPH), CYCLE GRAPH, STAR GRAPH, WHEEL GRAPH

### Cyclic Group

A cyclic group  $Z_n$  of ORDER  $n$  is a GROUP defined by the element  $X$  (the GENERATOR) and its  $n$  POWERS up to

$$X^n = I,$$

where  $I$  is the IDENTITY ELEMENT. Cyclic groups are both ABELIAN and SIMPLE. There exists a unique cyclic group of every order  $n \geq 2$ , so cyclic groups of the same order are always isomorphic (Shanks 1993, p. 74), and all GROUPS of PRIME ORDER are cyclic.

Examples of cyclic groups include  $Z_2$ ,  $Z_3$ ,  $Z_4$ , and the MODULO MULTIPLICATION GROUPS  $M_m$  such that  $m = 2, 4, p^n$ , or  $2p^n$ , for  $p$  an ODD PRIME and  $n \geq 1$  (Shanks 1993, p. 92). By computing the CHARACTERISTIC FACTORS, any ABELIAN GROUP can be expressed as a DIRECT PRODUCT of cyclic SUBGROUPS, for example,  $Z_2 \otimes Z_4$  or  $Z_2 \otimes Z_2 \otimes Z_2$ .

### Cyclic Hexagon

A hexagon (not necessarily regular) on whose VERTICES a CIRCLE may be CIRCUMSCRIBED. Let

$$\sigma_i \equiv \sum_{i,j,\dots,n=1} a_i^2 a_j^2 \dots a_n^2, \quad (1)$$

where the sum runs over all distinct permutations of the SQUARES of the six side lengths, so

$$\sigma_1 = a_1^2 + a_2^2 + a_3^2 + a_4^2 + a_5^2 + a_6^2 \quad (2)$$

$$\begin{aligned} \sigma_2 = & a_1^2 a_2^2 + a_1^2 a_3^2 + a_1^2 a_4^2 + a_1^2 a_5^2 + a_1^2 a_6^2 \\ & + a_2^2 a_3^2 + a_2^2 a_4^2 + a_2^2 a_5^2 + a_2^2 a_6^2 \\ & + a_3^2 a_4^2 + a_3^2 a_5^2 + a_3^2 a_6^2 \\ & + a_4^2 a_5^2 + a_4^2 a_6^2 + a_5^2 a_6^2 \end{aligned} \quad (3)$$

$$\begin{aligned} \sigma_3 = & a_1^2 a_2^2 a_3^2 + a_1^2 a_2^2 a_4^2 + a_1^2 a_2^2 a_5^2 + a_1^2 a_2^2 a_6^2 \\ & + a_2^2 a_3^2 a_4^2 + a_2^2 a_3^2 a_5^2 + a_2^2 a_3^2 a_6^2 \\ & + a_3^2 a_4^2 a_5^2 + a_3^2 a_4^2 a_6^2 + a_4^2 a_5^2 a_6^2 \end{aligned} \quad (4)$$

$$\begin{aligned} \sigma_4 = & a_1^2 a_2^2 a_3^2 a_4^2 + a_1^2 a_2^2 a_3^2 a_5^2 + a_1^2 a_2^2 a_3^2 a_6^2 \\ & + a_1^2 a_3^2 a_4^2 a_5^2 + a_1^2 a_3^2 a_4^2 a_6^2 \\ & + a_1^2 a_3^2 a_5^2 a_6^2 + a_1^2 a_4^2 a_5^2 a_6^2 \\ & + a_2^2 a_3^2 a_4^2 a_5^2 + a_2^2 a_3^2 a_4^2 a_6^2 + a_2^2 a_3^2 a_5^2 a_6^2 \\ & + a_2^2 a_4^2 a_5^2 a_6^2 + a_3^2 a_4^2 a_5^2 a_6^2 \end{aligned} \quad (5)$$

$$\begin{aligned} \sigma_5 = & a_1^2 a_2^2 a_3^2 a_4^2 a_5^2 + a_1^2 a_2^2 a_3^2 a_4^2 a_6^2 \\ & + a_1^2 a_2^2 a_3^2 a_5^2 a_6^2 + a_1^2 a_2^2 a_4^2 a_5^2 a_6^2 \\ & + a_1^2 a_3^2 a_4^2 a_5^2 a_6^2 + a_2^2 a_3^2 a_4^2 a_5^2 a_6^2 \end{aligned} \quad (6)$$

$$\sigma_6 = a_1^2 a_2^2 a_3^2 a_4^2 a_5^2 a_6^2. \quad (7)$$

Then define

$$t_2 = u - 4\sigma_2 + \sigma_1^2 \quad (8)$$

$$t_3 = 8\sigma_3 + \sigma_1 t_2 - 16\sqrt{\sigma_6} \quad (9)$$

$$t_4 = t_2^2 - 64\sigma_4 + 64\sigma_1\sqrt{\sigma_6} \quad (10)$$

$$t_5 = 128\sigma_5 + 32t_2\sqrt{\sigma_6} \quad (11)$$

$$u = 16K^2. \quad (12)$$

The AREA of the hexagon then satisfies

$$ut_4^3 + t_3^2 t_4^2 - 16t_3^3 t_5 - 18ut_3 t_4 t_5 - 27u^2 t_5^2 = 0, \quad (13)$$

or this equation with  $\sqrt{\sigma_6}$  replaced by  $-\sqrt{\sigma_6}$ , a seventh order POLYNOMIAL in  $u$ . This is  $1/(4u^2)$  times the DISCRIMINANT of the CUBIC EQUATION

$$z^3 + 2t_3 z^2 - ut_4 z + 2y^2 t_5. \quad (14)$$

### Cyclic-Inscriptable Quadrilateral

see BICENTRIC QUADRILATERAL

### Cyclic Number

A number having  $n-1$  DIGITS which, when MULTIPLIED by 1, 2, 3, ...,  $n-1$ , produces the same digits in a different order. Cyclic numbers are generated by the UNIT FRACTIONS  $1/n$  which have maximal period DECIMAL EXPANSIONS (which means  $n$  must be PRIME). The first few numbers which generate cyclic numbers are 7, 17, 19, 23, 29, 47, 59, 61, 97, ... (Sloane's A001913). A much larger generator is 17389.

It has been conjectured, but not yet proven, that an INFINITE number of cyclic numbers exist. In fact, the FRACTION of PRIMES which generate cyclic numbers seems to be approximately  $3/8$ . See Yates (1973) for a table of PRIME period lengths for PRIMES  $< 1,370,471$ . When a cyclic number is multiplied by its generator, the result is a string of 9s. This is a special case of MIDY'S THEOREM.

### Cyclic Pentagon

A cyclic pentagon is a not necessarily regular PENTAGON on whose VERTICES a CIRCLE may be CIRCUMSCRIBED. Let

$$\sigma_i \equiv \sum_{i,j,\dots,n=1} a_i^2 a_j^2 \cdots a_n^2, \quad (1)$$

where the SUM runs over all distinct PERMUTATIONS of the SQUARES of the 5 side lengths, so

$$\sigma_1 = a_1^2 + a_2^2 + a_3^2 + a_4^2 + a_5^2 \quad (2)$$

$$\begin{aligned} \sigma_2 = & a_1^2 a_2^2 + a_1^2 a_3^2 + a_1^2 a_4^2 + a_1^2 a_5^2 + a_2^2 a_3^2 \\ & + a_2^2 a_4^2 + a_2^2 a_5^2 + a_3^2 a_4^2 + a_3^2 a_5^2 \\ & + a_4^2 a_5^2 \end{aligned} \quad (3)$$

$$\begin{aligned} \sigma_3 = & a_1^2 a_2^2 a_3^2 + a_1^2 a_2^2 a_4^2 + a_1^2 a_2^2 a_5^2 \\ & + a_2^2 a_3^2 a_4^2 + a_2^2 a_3^2 a_5^2 + a_3^2 a_4^2 a_5^2 \end{aligned} \quad (4)$$

$$\begin{aligned} \sigma_4 = & a_1^2 a_2^2 a_3^2 a_4^2 + a_1^2 a_2^2 a_3^2 a_5^2 + a_1^2 a_3^2 a_4^2 a_5^2 \\ & + a_2^2 a_3^2 a_4^2 a_5^2 \end{aligned} \quad (5)$$

$$\sigma_5 = a_1^2 a_2^2 a_3^2 a_4^2 a_5^2. \quad (6)$$

Then define

$$t_2 = u - 4\sigma_2 + \sigma_1^2 \quad (7)$$

$$t_3 = 8\sigma_3 + \sigma_1 t_2 \quad (8)$$

$$t_4 = -64\sigma_4 + t_2^2 \quad (9)$$

$$t_5 = 128\sigma_5 \quad (10)$$

$$u = 16K^2. \quad (11)$$

The AREA of the pentagon then satisfies

$$ut_4^3 + t_3^2 t_4^2 - 16t_3^3 t_5 - 18ut_3 t_4 t_5 - 27u^2 t_5^2 = 0, \quad (12)$$

a seventh order POLYNOMIAL in  $u$ . This is  $1/(4u^2)$  times the DISCRIMINANT of the CUBIC EQUATION

$$z^3 + 2t_3 z^2 - ut_4 z + 2y^2 t_5. \quad (13)$$

see also CONCYCLIC, CYCLIC HEXAGON, CYCLIC POLYGON

### References

- Robbins, D. P. "Areas of Polygons Inscribed in a Circle." *Discr. Comput. Geom.* **12**, 223–236, 1994.

### Cyclic Permutation

A PERMUTATION which shifts all elements of a SET by a fixed offset, with the elements shifted off the end inserted back at the beginning. For a SET with elements  $a_0, a_1, \dots, a_{n-1}$ , this can be written  $a_i \rightarrow a_{i+k \pmod n}$  for a shift of  $k$ .

see also PERMUTATION

### Cyclic Polygon

A cyclic polygon is a POLYGON with VERTICES upon which a CIRCLE can be CIRCUMSCRIBED. Since every TRIANGLE has a CIRCUMCIRCLE, every TRIANGLE is cyclic. It is conjectured that for a cyclic polygon of  $2m + 1$  sides,  $16K^2$  (where  $K$  is the AREA) satisfies a MONIC POLYNOMIAL of degree  $\Delta_m$ , where

$$\Delta_m \equiv \sum_{k=0}^{m-1} (m-k) \binom{2m+1}{k} \quad (1)$$

$$= \frac{1}{2} \left[ (2m+1) \binom{2m}{m} - 2^{2m} \right] \quad (2)$$

(Robbins 1995). It is also conjectured that a cyclic polygon with  $2m + 2$  sides satisfies one of two POLYNOMIALS of degree  $\Delta_m$ . The first few values of  $\Delta_m$  are 1, 7, 38, 187, 874, ... (Sloane's A000531).

For TRIANGLES ( $n = 3 = 2 \cdot 1 + 1$ ), the POLYNOMIAL is HERON'S FORMULA, which may be written

$$16K^2 = 2a^2 b^2 + 2a^2 c^2 + 2b^2 c^2 - a^4 - b^4 - c^4, \quad (3)$$

and which is of order  $\Delta_1 = 1$  in  $16K^2$ . For a CYCLIC QUADRILATERAL, the POLYNOMIAL is BRAHMACUPTA'S FORMULA, which may be written

$$\begin{aligned} 16K^2 = & -a^4 + 2a^2 b^2 - b^4 + 2a^2 c^2 + 2b^2 c^2 - c^4 \\ & + 8abcd + 2a^2 d^2 + 2b^2 d^2 + 2c^2 d^2 - d^4, \end{aligned} \quad (4)$$

which is of order  $\Delta_1 = 1$  in  $16K^2$ . Robbins (1995) gives the corresponding FORMULAS for the CYCLIC PENTAGON and CYCLIC HEXAGON.

### Cyclic Quadrangle

Let  $A_1, A_2, A_3$ , and  $A_4$  be four POINTS on a CIRCLE, and  $H_1, H_2, H_3, H_4$  the ORTHOCENTERS of TRIANGLES  $\Delta A_2 A_3 A_4$ , etc. If, from the eight POINTS, four with different subscripts are chosen such that three are from one set and the fourth from the other, these POINTS form an ORTHOCENTRIC SYSTEM. There are eight such systems, which are analogous to the six sets of ORTHOCENTRIC SYSTEMS obtained using the feet of the ANGLE BISECTORS, ORTHOCENTER, and VERTICES of a generic TRIANGLE.

On the other hand, if all the POINTS are chosen from one set, or two from each set, with all different subscripts, the four POINTS lie on a CIRCLE. There are four pairs of such CIRCLES, and eight POINTS lie by fours on eight equal CIRCLES.

The SIMSON LINE of  $A_4$  with regard to TRIANGLE  $\Delta A_1 A_2 A_3$  is the same as that of  $H_4$  with regard to the TRIANGLE  $\Delta H_1 A_2 A_3$ .

### Cyclic Quadrilateral

A QUADRILATERAL for which a CIRCLE can be circumscribed so that it touches each VERTEX. The AREA is then given by a special case of BRETSCHNEIDER'S FORMULA. Let the sides have lengths  $a, b, c$ , and  $d$ , let  $s$  be the SEMIPERIMETER

$$s = \frac{1}{2}(a + b + c + d), \quad (1)$$

and let  $R$  be the CIRCUMRADIUS. Then

$$A = \sqrt{(s-a)(s-b)(s-c)(s-d)} \quad (2)$$

$$= \frac{\sqrt{(ac+bd)(ad+bc)(ab+cd)}}{4R}. \quad (3)$$

Solving for the CIRCUMRADIUS gives

$$R = \frac{1}{4} \sqrt{\frac{(ac+bd)(ad+bc)(ab+cd)}{(s-a)(s-b)(s-c)(s-d)}}. \quad (4)$$

The DIAGONALS of a cyclic quadrilateral have lengths

$$p = \sqrt{\frac{(ab+cd)(ac+bd)}{ad+bc}} \quad (5)$$

$$q = \sqrt{\frac{(ac+bd)(ad+bc)}{ab+cd}}, \quad (6)$$

so that  $pq = ac + bd$ . In general, there are three essentially distinct cyclic quadrilaterals (modulo ROTATION and REFLECTION) whose edges are permutations of the lengths  $a, b, c$ , and  $d$ . Of the six corresponding DIAGONAL lengths, three are distinct. In addition to  $p$  and  $q$ , there is therefore a "third" DIAGONAL which can be denoted  $r$ . It is given by the equation

$$r = \sqrt{\frac{(ad+bc)(ab+cd)}{ac+bd}}. \quad (7)$$

This allows the AREA formula to be written in the particularly beautiful and simple form

$$A = \frac{pqr}{4R}. \quad (8)$$

The DIAGONALS are sometimes also denoted  $p, q$ , and  $r$ .

The AREA of a cyclic quadrilateral is the MAXIMUM possible for any QUADRILATERAL with the given side lengths. Also, the opposite ANGLES of a cyclic quadrilateral sum to  $\pi$  RADIANS (Dunham 1990).

A cyclic quadrilateral with RATIONAL sides  $a, b, c$ , and  $d$ , DIAGONALS  $p$  and  $q$ , CIRCUMRADIUS  $R$ , and AREA  $A$  is given by  $a = 25, b = 33, c = 39, d = 65, p = 60, q = 52, R = 65/2$ , and  $A = 1344$ .

Let  $AHBO$  be a QUADRILATERAL such that the angles  $\angle HAB$  and  $\angle HOB$  are RIGHT ANGLES, then  $AHBO$  is a cyclic quadrilateral (Dunham 1990). This is a COROLLARY of the theorem that, in a RIGHT TRIANGLE, the MIDPOINT of the HYPOTENUSE is equidistant from the

three VERTICES. Since  $M$  is the MIDPOINT of both RIGHT TRIANGLES  $\triangle AHB$  and  $\triangle BOH$ , it is equidistant from all four VERTICES, so a CIRCLE centered at  $M$  may be drawn through them. This theorem is one of the building blocks of Heron's derivation of HERON'S FORMULA.

Place four equal CIRCLES so that they intersect in a point. The quadrilateral  $ABCD$  is then a cyclic quadrilateral (Honsberger 1991). For a CONVEX cyclic quadrilateral  $Q$ , consider the set of CONVEX cyclic quadrilaterals  $Q_{||}$  whose sides are PARALLEL to  $Q$ . Then the  $Q_{||}$  of maximal AREA is the one whose DIAGONALS are PERPENDICULAR (Gürel 1996).

### Cyclid

see CYCLIDE

### Cyclide

A pair of focal conics which are the envelopes of two one-parameter families of spheres, sometimes also called a CYCLID. The cyclide is a QUARTIC SURFACE, and the lines of curvature on a cyclide are all straight lines or circular arcs (Pinkall 1986). The STANDARD TORI and their inversions in a SPHERE  $S$  centered at a point  $\mathbf{x}_0$  and of RADIUS  $r$ , given by

$$I(\mathbf{x}_0, r) = \mathbf{x}_0 + \frac{\mathbf{x} - \mathbf{x}_0 r^2}{|\mathbf{x} - \mathbf{x}_0|^2},$$

are both cyclides (Pinkall 1986). Illustrated above are RING CYCLIDES, HORN CYCLIDES, and SPINDLE CYCLIDES. The figures on the right correspond to  $\mathbf{x}_0$  lying on the torus itself, and are called the PARABOLIC RING CYCLIDE, PARABOLIC HORN CYCLIDE, and PARABOLIC SPINDLE CYCLIDE, respectively.

## Cycloid

The cycloid is the locus of a point on the rim of a CIRCLE of RADIUS  $a$  rolling along a straight LINE. It was studied and named by Galileo in 1599. Galileo attempted to find the AREA by weighing pieces of metal cut into the shape of the cycloid. Torricelli, Fermat, and Descartes all found the AREA. The cycloid was also studied by Roberval in 1634, Wren in 1658, Huygens in 1673, and Johann Bernoulli in 1696. Roberval and Wren found the ARC LENGTH (MacTutor Archive). Gear teeth were also made out of cycloids, as first proposed by Desargues in the 1630s (Cundy and Rollett 1989).

In 1696, Johann Bernoulli challenged other mathematicians to find the curve which solves the BRACHISTOCHRON PROBLEM, knowing the solution to be a cycloid. Leibniz, Newton, Jakob Bernoulli and L'Hospital all solved Bernoulli's challenge. The cycloid also solves the TAUTOCHRON PROBLEM. Because of the frequency with which it provoked quarrels among mathematicians

in the 17th century, the cycloid became known as the "Helen of Geometers" (Boyer 1968, p. 389).

The cycloid is the CATACAUSTIC of a CIRCLE for a RADIANT POINT on the circumference, as shown by Jakob and Johann Bernoulli in 1692. The CAUSTIC of the cycloid when the rays are parallel to the  $y$ -axis is a cycloid with twice as many arches. The RADIAL CURVE of a CYCLOID is a CIRCLE. The EVOLUTE and INVOLUTE of a cycloid are identical cycloids.

If the cycloid has a CUSP at the ORIGIN, its equation in CARTESIAN COORDINATES is

$$x = a \cos^{-1} \left( \frac{a-y}{a} \right) \mp \sqrt{2ay - y^2}. \quad (1)$$

In parametric form, this becomes

$$x = a(t - \sin t) \quad (2)$$

$$y = a(1 - \cos t). \quad (3)$$

If the cycloid is upside-down with a cusp at  $(0, a)$ , (2) and (3) become

$$x = 2a \sin^{-1} \left( \frac{y}{2a} \right) + \sqrt{2ay - y^2} \quad (4)$$

or

$$x = a(t + \sin t) \quad (5)$$

$$y = a(1 - \cos t) \quad (6)$$

(sign of  $\sin t$  flipped for  $x$ ).

The DERIVATIVES of the parametric representation (2) and (3) are

$$x' = a(1 - \cos t) \quad (7)$$

$$y' = a \sin t \quad (8)$$

$$\begin{aligned} \frac{dy}{dx} &= \frac{y'}{x'} = \frac{a \sin t}{a(1 - \cos t)} = \frac{\sin t}{1 - \cos t} \\ &= \frac{2 \sin(\frac{1}{2}t) \cos(\frac{1}{2}t)}{2 \sin^2(\frac{1}{2}t)} = \cot(\frac{1}{2}t). \end{aligned} \quad (9)$$

The squares of the derivatives are

$$x'^2 = a^2(1 - 2 \cos t + \cos^2 t) \quad (10)$$

$$y'^2 = a^2 \sin^2 t, \quad (11)$$

so the ARC LENGTH of a single cycle is

$$\begin{aligned} L &= \int ds = \int_0^{2\pi} \sqrt{x'^2 + y'^2} dt \\ &= a \int_0^{2\pi} \sqrt{(1 - 2 \cos t + \cos^2 t) + \sin^2 t} dt \\ &= a\sqrt{2} \int_0^{2\pi} \sqrt{1 - \cos t} dt = 2a \int_0^{2\pi} \sqrt{\frac{1 - \cos t}{2}} dt \\ &= 2a \int_0^{2\pi} |\sin(\frac{1}{2}t)| dt. \end{aligned} \quad (12)$$

Now let  $u \equiv t/2$  so  $du = dt/2$ . Then

$$\begin{aligned} L &= 4a \int_0^\pi \sin u \, du = 4a[-\cos u]_0^\pi \\ &= -4a[(-1) - 1] = 8a. \end{aligned} \quad (13)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s = 8a \sin^2(\tfrac{1}{4}t) \quad (14)$$

$$\kappa = -\tfrac{1}{4}a \csc(\tfrac{1}{2}t) \quad (15)$$

$$\phi = -\tfrac{1}{2}at. \quad (16)$$

The AREA under a single cycle is

$$\begin{aligned} A &= \int_0^{2\pi} y \, dx = a^2 \int_0^{2\pi} (1 - \cos \phi)(1 - \cos \phi) \, d\phi \\ &= a^2 \int_0^{2\pi} (1 - \cos \phi)^2 \, d\phi \\ &= a^2 \int_0^{2\pi} (1 - 2\cos \phi + \cos^2 \phi) \, d\phi \\ &= a^2 \int_0^{2\pi} \{1 - 2\cos \phi + \tfrac{1}{2}[1 + \cos(2\phi)]\} \, d\phi \\ &= a^2 \int_0^{2\pi} [\tfrac{3}{2} - 2\cos \phi + \tfrac{1}{2}\cos(2\phi)] \, d\phi \\ &= a^2 [\tfrac{3}{2}\phi - 2\sin \phi + \tfrac{1}{4}\sin(2\phi)]_0^{2\pi} \\ &= a^2 \tfrac{3}{2}2\pi = 3\pi a^2. \end{aligned} \quad (17)$$

The NORMAL is

$$\hat{\mathbf{T}} = \frac{1}{\sqrt{2 - 2\cos t}} \begin{bmatrix} 1 - \cos t \\ \sin t \end{bmatrix}. \quad (18)$$

#### Cycloid Evolute

The EVOLUTE of the CYCLOID

$$x(t) = a(t - \sin t)$$

$$y(t) = a(1 - \cos t)$$

is given by

$$x(t) = a(t + \sin t)$$

$$y(t) = a(\cos t - 1).$$

As can be seen in the above figure, the EVOLUTE is simply a shifted copy of the original CYCLOID, so the CYCLOID is its own EVOLUTE.

#### Cycloid Involute

The INVOLUTE of the CYCLOID

$$x(t) = a(t - \sin t)$$

$$y(t) = a(1 - \cos t)$$

is given by

$$x(t) = a(t + \sin t)$$

$$y(t) = a(3 + \cos t).$$

As can be seen in the above figure, the INVOLUTE is simply a shifted copy of the original CYCLOID, so the CYCLOID is its own INVOLUTE!

**Cycloid Radial Curve**

The RADIAL CURVE of the CYCLOID is the CIRCLE

$$\begin{aligned}x &= x_0 + 2a \sin \phi \\ y &= -2a + y_0 + 2a \cos \phi.\end{aligned}$$

**Cyclomatic Number**

see CIRCUIT RANK

**Cyclotomic Equation**

The equation

$$x^p = 1,$$

where solutions  $\zeta_k = e^{2\pi i k/p}$  are the ROOTS OF UNITY sometimes called DE MOIVRE NUMBERS. Gauss showed that the cyclotomic equation can be reduced to solving a series of QUADRATIC EQUATIONS whenever  $p$  is a FERMAT PRIME. Wantzel (1836) subsequently showed that this condition is not only SUFFICIENT, but also NECESSARY. An “irreducible” cyclotomic equation is an expression of the form

$$\frac{x^p - 1}{x - 1} = x^{p-1} + x^{p-2} + \dots + 1 = 0,$$

where  $p$  is PRIME. Its ROOTS  $z_i$  satisfy  $|z_i| = 1$ .

see also CYCLOTOMIC POLYNOMIAL, DE MOIVRE NUMBER, POLYGON, PRIMITIVE ROOT OF UNITY

 Wantzel, P. L. “Recherches sur les moyens de reconnaître si un Problème de Géométrie peut se résoudre avec la règle et le compas.” *J. Math. pures appliq.* **1**, 366–372, 1836.

**Cyclotomic Factorization**

$$z^p - y^p = (z - y)(z - \zeta y) \cdots (z - \zeta^{p-1} y),$$

where  $\zeta \equiv e^{2\pi i/p}$  (a DE MOIVRE NUMBER) and  $p$  is a PRIME.

**Cyclotomic Field**

The smallest field containing  $m \in \mathbb{Z} \geq 1$  with  $\zeta$  a PRIME ROOT OF UNITY is denoted  $\mathbb{R}_m(\zeta)$ .

$$x^p + y^p = \prod_{k=1}^p (x + \zeta^k y).$$

Specific cases are

$$\begin{aligned}\mathbb{R}_3 &= \mathbb{Q}(\sqrt{-3}) \\ \mathbb{R}_4 &= \mathbb{Q}(\sqrt{-1}) \\ \mathbb{R}_6 &= \mathbb{Q}(\sqrt{-3}),\end{aligned}$$

where  $\mathbb{Q}$  denotes a QUADRATIC FIELD.

**Cyclotomic Integer**

A number of the form

$$a_0 + a_1 \zeta + \dots + a_{p-1} \zeta^{p-1},$$

where

$$\zeta \equiv e^{2\pi i/p}$$

is a DE MOIVRE NUMBER and  $p$  is a PRIME number. Unique factorizations of cyclotomic INTEGERS fail for  $p > 23$ .

**Cyclotomic Invariant**

Let  $p$  be an ODD PRIME and  $F_n$  the CYCLOTOMIC FIELD of  $p^{n+1}$ th ROOTS of unity over the rational FIELD. Now let  $p^{e(n)}$  be the POWER of  $p$  which divides the CLASS NUMBER  $h_n$  of  $F_n$ . Then there exist INTEGERS  $\mu_p, \lambda_p \geq 0$  and  $\nu_p$  such that

$$e(n) = \mu_p p^n + \lambda_p n + \nu_p$$

for all sufficiently large  $n$ . For REGULAR PRIMES,  $\mu_p = \lambda_p = \nu_p = 0$ .

**References**

- Johnson, W. “Irregular Primes and Cyclotomic Invariants.” *Math. Comput.* **29**, 113–120, 1975.

**Cyclotomic Number**

see DE MOIVRE NUMBER, SYLVESTER CYCLOTOMIC NUMBER

**Cyclotomic Polynomial**

A polynomial given by

$$\Phi_d(x) = \prod_{k=1}^d (x - \zeta_k), \quad (1)$$

where  $\zeta_i$  are the primitive  $d$ th ROOTS OF UNITY in  $\mathbb{C}$  given by  $\zeta_k = e^{2\pi i k/d}$ . The numbers  $\zeta_k$  are sometimes called DE MOIVRE NUMBERS.  $\Phi_d(x)$  is an irreducible

POLYNOMIAL in  $\mathbb{Z}[x]$  with degree  $\phi(d)$ , where  $\phi$  is the TOTIENT FUNCTION. For  $d$  PRIME,

$$\Phi_p = \sum_{k=0}^{p-1} x^k, \quad (2)$$

i.e., the coefficients are all 1.  $\Phi_{105}$  has coefficients of  $-2$  for  $x^7$  and  $x^{41}$ , making it the first cyclotomic polynomial to have a coefficient other than  $\pm 1$  and 0. This is true because 105 is the first number to have three distinct ODD PRIME factors, i.e.,  $105 = 3 \cdot 5 \cdot 7$  (McClellan and Rader 1979, Schroeder 1997). Migotti (1883) showed that COEFFICIENTS of  $\Phi_{pq}$  for  $p$  and  $q$  distinct PRIMES can be only 0,  $\pm 1$ . Lam and Leung (1996) considered

$$\Phi_{pq} \equiv \sum_{k=0}^{pq-1} a_k x^k \quad (3)$$

for  $p, q$  PRIME. Write the TOTIENT FUNCTION as

$$\phi(pq) = (p-1)(q-1) = rp + sq \quad (4)$$

and let

$$0 \leq k \leq (p-1)(q-1), \quad (5)$$

then

1.  $a_k = 1$  IFF  $k = ip + jq$  for some  $i \in [0, r]$  and  $j \in [0, s]$ ,
2.  $a_k = -1$  IFF  $k + pq = ip + jq$  for  $i \in [r+1, q-1]$  and  $j \in [s+1, p-1]$ ,
3. otherwise  $a_k = 0$ .

The number of terms having  $a_k = 1$  is  $(r+1)(s+1)$ , and the number of terms having  $a_k = -1$  is  $(p-s-1)(q-r-1)$ . Furthermore, assume  $q > p$ , then the middle COEFFICIENT of  $\Phi_{pq}$  is  $(-1)^r$ .

The LOGARITHM of the cyclotomic polynomial

$$\Phi_n(x) = \prod_{d|n} (1 - x^{n/d})^{\mu(d)} \quad (6)$$

is the MÖBIUS INVERSION FORMULA (Vardi 1991, p. 225).

The first few cyclotomic POLYNOMIALS are

$$\begin{aligned} \Phi_1(x) &= x - 1 \\ \Phi_2(x) &= x + 1 \\ \Phi_3(x) &= x^2 + x + 1 \\ \Phi_4(x) &= x^2 + 1 \\ \Phi_5(x) &= x^4 + x^3 + x^2 + x + 1 \\ \Phi_6(x) &= x^2 - x + 1 \\ \Phi_7(x) &= x^6 + x^5 + x^4 + x^3 + x^2 + x + 1 \\ \Phi_8(x) &= x^4 + 1 \\ \Phi_9(x) &= x^6 + x^3 + 1 \\ \Phi_{10}(x) &= x^4 - x^3 + x^2 - x + 1. \end{aligned}$$

The smallest values of  $n$  for which  $\Phi_n$  has one or more coefficients  $\pm 1, \pm 2, \pm 3, \dots$  are 0, 105, 385, 1365, 1785, 2805, 3135, 6545, 6545, 10465, 10465, 10465, 10465, 10465, 11305,  $\dots$  (Sloane's A013594).

The POLYNOMIAL  $x^n - 1$  can be factored as

$$x^n - 1 = \prod_{d|n} \Phi_d(x), \quad (7)$$

where  $\Phi_d(x)$  is a CYCLOTOMIC POLYNOMIAL. Furthermore,

$$x^n + 1 = \frac{x^{2n-1}}{x^n - 1} = \frac{\prod_{d|2n} \Phi_d(x)}{\prod_{d|n} \Phi_d(x)} = \prod_{d|m} \Phi_{2^t d}(x). \quad (8)$$

The COEFFICIENTS of the inverse of the cyclotomic POLYNOMIAL

$$\begin{aligned} \frac{1}{1+x+x^2} &= 1 - x + x^3 - x^4 + x^6 - x^7 + x^9 - x^{10} + \dots \\ &= \sum_{n=0}^{\infty} c_n x^n \end{aligned} \quad (9)$$

can also be computed from

$$c_n = 1 - 2 \left\lfloor \frac{1}{3}(n+2) \right\rfloor + \left\lfloor \frac{1}{3}(n+1) \right\rfloor + \left\lfloor \frac{1}{3}n \right\rfloor, \quad (10)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION.

**Cylinder**

A cylinder is a solid of circular CROSS-SECTION in which the centers of the CIRCLES all lie on a single LINE. The cylinder was extensively studied by Archimedes in his 2-volume work *On the Sphere and Cylinder* in ca. 225 BC.

A cylinder is called a right cylinder if it is “straight” in the sense that its cross-sections lie directly on top of each other; otherwise, the cylinder is called oblique. The surface of a cylinder of height  $h$  and RADIUS  $r$  can be described parametrically by

$$x = r \cos \theta \quad (1)$$

$$y = r \sin \theta \quad (2)$$

$$z = z, \quad (3)$$

for  $z \in [0, h]$  and  $\theta \in [0, 2\pi)$ . These are the basis for CYLINDRICAL COORDINATES. The SURFACE AREA (of the sides) and VOLUME of the cylinder of height  $h$  and RADIUS  $r$  are

$$S = 2\pi r h \quad (4)$$

$$V = \pi r^2 h. \quad (5)$$

Therefore, if top and bottom caps are added, the volume-to-surface area ratio for a cylindrical container is

$$\frac{V}{S} = \frac{\pi r^2 h}{2\pi r h + 2\pi r^2} = \frac{1}{2} \left( \frac{1}{r} + \frac{1}{h} \right)^{-1}, \quad (6)$$

which is related to the HARMONIC MEAN of the radius  $r$  and height  $h$ .

**Cylinder Cutting**

The maximum number of pieces into which a cylinder can be divided by  $n$  oblique cuts is given by

$$f(n) = \binom{n+1}{3} + n + 1 = \frac{1}{6}(n+2)(n+3),$$

where  $\binom{a}{b}$  is a BINOMIAL COEFFICIENT. This problem is sometimes also called CAKE CUTTING or PIE CUTTING. For  $n = 1, 2, \dots$  cuts, the maximum number of pieces is 2, 4, 8, 15, 26, 42, ... (Sloane's A000125).

**Cylinder-Cylinder Intersection**

see STEINMETZ SOLID

**Cylinder Function**

The cylinder function is defined as

$$C(x, y) \equiv \begin{cases} 1 & \text{for } \sqrt{x^2 + y^2} \leq a \\ 0 & \text{for } \sqrt{x^2 + y^2} > a. \end{cases} \quad (1)$$

The BESSEL FUNCTIONS are sometimes also called cylinder functions. To find the FOURIER TRANSFORM of the cylinder function, let

$$k_x = k \cos \alpha \quad (2)$$

$$k_y = k \sin \alpha \quad (3)$$

$$x = r \cos \theta \quad (4)$$

$$y = r \sin \theta. \quad (5)$$

Then

$$\begin{aligned} F(k, a) &= \mathcal{F}(C(x, y)) \\ &= \int_0^{2\pi} \int_0^a e^{i(k \cos \alpha r \cos \theta + k \sin \alpha r \sin \theta)} r dr d\theta \\ &= \int_0^{2\pi} \int_0^a e^{i k r \cos(\theta - \alpha)} r dr d\theta. \end{aligned} \quad (6)$$

Let  $b = \theta - \alpha$ , so  $db = d\theta$ . Then

$$\begin{aligned} F(k, a) &= \int_{-\alpha}^{2\pi - \alpha} \int_0^a e^{i k r \cos b} r dr d\theta \\ &= \int_0^{2\pi} \int_0^a e^{i k r \cos b} r dr db \\ &= 2\pi \int_0^a J_0(kr) r dr, \end{aligned} \quad (7)$$

where  $J_0$  is a zeroth order BESSEL FUNCTION OF THE FIRST KIND. Let  $u \equiv kr$ , so  $du = k dr$ , then

$$\begin{aligned} F(k, a) &= \frac{2\pi}{k^2} \int_0^{ka} J_0(u) u du = \frac{2\pi}{k^2} [u J_1(u)]_0^{ka} \\ &= \frac{2\pi a}{k} J_1(ka) = 2\pi a^2 \frac{J_1(ka)}{ka}. \end{aligned} \quad (8)$$

As defined by Watson (1966), a "cylinder function" is any function which satisfies the RECURRENCE RELATIONS

$$C_{\nu-1}(z) + C_{\nu+1}(z) = \frac{2\nu}{z} C_{\nu}(z) \quad (9)$$

$$C_{\nu-1}(z) - C_{\nu+1}(z) = 2C'_{\nu}(z). \quad (10)$$

This class of functions can be expressed in terms of BESSEL FUNCTIONS.

### Cylinder-Sphere Intersection

see VIVIANI'S CURVE

### Cylindrical Coordinates

Cylindrical coordinates are a generalization of 2-D POLAR COORDINATES to 3-D by superposing a height ( $z$ ) axis. Unfortunately, there are a number of different notations used for the other two coordinates. Either  $r$  or  $\rho$  is used to refer to the radial coordinate and either  $\phi$  or  $\theta$  to the azimuthal coordinates. Arfken (1985), for instance, uses  $(\rho, \phi, z)$ , while Beyer (1987) uses  $(r, \theta, z)$ . In this work, the NOTATION  $(r, \theta, z)$  is used.

$$r = \sqrt{x^2 + y^2} \quad (1)$$

$$\theta = \tan^{-1} \left( \frac{y}{x} \right) \quad (2)$$

$$z = z, \quad (3)$$

where  $r \in [0, \infty)$ ,  $\theta \in [0, 2\pi)$ , and  $z \in (-\infty, \infty)$ . In terms of  $x$ ,  $y$ , and  $z$

$$x = r \cos \theta \quad (4)$$

$$y = r \sin \theta \quad (5)$$

$$z = z. \quad (6)$$

Morse and Feshbach (1953) define the cylindrical coordinates by

$$x = \xi_1 \xi_2 \quad (7)$$

$$y = \xi_1 \sqrt{1 - \xi_2^2} \quad (8)$$

$$z = \xi_3, \quad (9)$$

where  $\xi_1 = r$  and  $\xi_2 = \cos \theta$ . The METRIC elements of the cylindrical coordinates are

$$g_{rr} = 1 \quad (10)$$

$$g_{\theta\theta} = r^2 \quad (11)$$

$$g_{zz} = 1, \quad (12)$$

so the SCALE FACTORS are

$$g_r = 1 \quad (13)$$

$$g_{\theta} = r \quad (14)$$

$$g_z = 1. \quad (15)$$

The LINE ELEMENT is

$$ds = dr \hat{\mathbf{r}} + r d\theta \hat{\boldsymbol{\theta}} + dz \hat{\mathbf{z}}, \quad (16)$$

and the VOLUME ELEMENT is

$$dV = r dr d\theta dz. \quad (17)$$

The JACOBIAN is

$$\left| \frac{\partial(x, y, z)}{\partial(r, \theta, z)} \right| = r. \quad (18)$$

A CARTESIAN VECTOR is given in CYLINDRICAL COORDINATES by

$$\mathbf{r} = \begin{bmatrix} r \cos \theta \\ r \sin \theta \\ z \end{bmatrix}. \quad (19)$$

To find the UNIT VECTORS,

$$\hat{\mathbf{r}} \equiv \frac{d\mathbf{r}}{dr} = \begin{bmatrix} \cos \theta \\ \sin \theta \\ 0 \end{bmatrix} \quad (20)$$

$$\hat{\boldsymbol{\theta}} \equiv \frac{d\mathbf{r}}{d\theta} = \begin{bmatrix} -\sin \theta \\ \cos \theta \\ 0 \end{bmatrix} \quad (21)$$

$$\hat{\mathbf{z}} \equiv \frac{d\mathbf{r}}{dz} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}. \quad (22)$$

Derivatives of unit VECTORS with respect to the coordinates are

$$\frac{\partial \hat{\mathbf{r}}}{\partial r} = \mathbf{0} \quad (23)$$

$$\frac{\partial \hat{\mathbf{r}}}{\partial \theta} = \begin{bmatrix} -\sin \theta \\ \cos \theta \\ 0 \end{bmatrix} = \hat{\boldsymbol{\theta}} \quad (24)$$

$$\frac{\partial \hat{\mathbf{r}}}{\partial z} = \mathbf{0} \quad (25)$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial r} = \mathbf{0} \quad (26)$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial \theta} = \begin{bmatrix} -\cos \theta \\ -\sin \theta \\ 0 \end{bmatrix} = -\hat{\mathbf{r}} \quad (27)$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial z} = \mathbf{0} \quad (28)$$

$$\frac{\partial \hat{\mathbf{z}}}{\partial r} = \mathbf{0} \quad (29)$$

$$\frac{\partial \hat{\mathbf{z}}}{\partial \theta} = \mathbf{0} \quad (30)$$

$$\frac{\partial \hat{\mathbf{z}}}{\partial z} = \mathbf{0}. \quad (31)$$

The GRADIENT of a VECTOR FIELD in cylindrical coordinates is given by

$$\nabla \equiv \hat{\mathbf{r}} \frac{\partial}{\partial r} + \hat{\boldsymbol{\theta}} \frac{1}{r} \frac{\partial}{\partial \theta} + \hat{\mathbf{z}} \frac{\partial}{\partial z}, \quad (32)$$

so the GRADIENT components become

$$\nabla_r \hat{\mathbf{r}} = \mathbf{0} \quad (33)$$

$$\nabla_\theta \hat{\mathbf{r}} = \frac{1}{r} \hat{\boldsymbol{\theta}} \quad (34)$$

$$\nabla_z \hat{\mathbf{r}} = \mathbf{0} \quad (35)$$

$$\nabla_r \hat{\boldsymbol{\theta}} = \mathbf{0} \quad (36)$$

$$\nabla_\theta \hat{\boldsymbol{\theta}} = -\frac{1}{r} \hat{\mathbf{r}} \quad (37)$$

$$\nabla_z \hat{\boldsymbol{\theta}} = \mathbf{0} \quad (38)$$

$$\nabla_r \hat{\mathbf{z}} = \mathbf{0} \quad (39)$$

$$\nabla_\theta \hat{\mathbf{z}} = \mathbf{0} \quad (40)$$

$$\nabla_z \hat{\mathbf{z}} = \mathbf{0}. \quad (41)$$

Now, since the CONNECTION COEFFICIENTS are defined by

$$\Gamma_{jk}^i = \hat{\mathbf{x}}_i \cdot (\nabla_k \hat{\mathbf{x}}_j), \quad (42)$$

$$\Gamma^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & -\frac{1}{r} & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (43)$$

$$\Gamma^\theta = \begin{bmatrix} 0 & \frac{1}{r} & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (44)$$

$$\Gamma^z = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \quad (45)$$

The COVARIANT DERIVATIVES, given by

$$A_{j;k} = \frac{1}{g^{kk}} \frac{\partial A_j}{\partial x_k} - \Gamma_{jk}^i A_i, \quad (46)$$

are

$$A_{r;r} = \frac{\partial A_r}{\partial r} - \Gamma_{rr}^i A_i = \frac{\partial A_r}{\partial r} \quad (47)$$

$$\begin{aligned} A_{r;\theta} &= \frac{1}{r} \frac{\partial A_r}{\partial \theta} - \Gamma_{r\theta}^i A_i = \frac{1}{r} \frac{\partial A_r}{\partial \theta} - \Gamma_{r\theta}^\theta A_\theta \\ &= \frac{1}{r} \frac{\partial A_r}{\partial \theta} - \frac{A_\theta}{r} \end{aligned} \quad (48)$$

$$A_{r;z} = \frac{\partial A_r}{\partial z} - \Gamma_{rz}^i A_i = \frac{\partial A_r}{\partial z} \quad (49)$$

$$A_{\theta;r} = \frac{\partial A_\theta}{\partial r} \Gamma_{\theta r}^i A_i = \frac{\partial A_\theta}{\partial r} \quad (50)$$

$$\begin{aligned} A_{\theta;\theta} &= \frac{1}{r} \frac{\partial A_\theta}{\partial \theta} - \Gamma_{\theta\theta}^i A_i = \frac{1}{r} \frac{\partial A_\theta}{\partial \theta} - \Gamma_{\theta\theta}^r A_r \\ &= \frac{1}{r} \frac{\partial A_\theta}{\partial \theta} + \frac{A_r}{r} \end{aligned} \quad (51)$$

$$A_{\theta;z} = \frac{\partial A_\theta}{\partial z} - \Gamma_{\theta z}^i A_i = \frac{\partial A_\theta}{\partial z} \quad (52)$$

$$A_{z;r} = \frac{\partial A_z}{\partial r} - \Gamma_{zr}^i A_i = \frac{\partial A_z}{\partial r} \quad (53)$$

$$A_{z;\theta} = \frac{1}{r} \frac{\partial A_z}{\partial \theta} - \Gamma_{z\theta}^i A_i = \frac{1}{r} \frac{\partial A_z}{\partial \theta} \quad (54)$$

$$A_{z;z} = \frac{\partial A_z}{\partial z} - \Gamma_{zz}^i A_i = \frac{\partial A_z}{\partial z}. \quad (55)$$

CROSS PRODUCTS of the coordinate axes are

$$\hat{\mathbf{r}} \times \hat{\mathbf{z}} = -\hat{\boldsymbol{\theta}} \quad (56)$$

$$\hat{\boldsymbol{\theta}} \times \hat{\mathbf{z}} = \hat{\mathbf{r}} \quad (57)$$

$$\hat{\mathbf{r}} \times \hat{\boldsymbol{\theta}} = \hat{\mathbf{z}}. \quad (58)$$

The COMMUTATION COEFFICIENTS are given by

$$c_{\alpha\beta}^\mu \vec{e}_\mu = [\vec{e}_\alpha, \vec{e}_\beta] = \nabla_\alpha \vec{e}_\beta - \nabla_\beta \vec{e}_\alpha, \quad (59)$$

But

$$[\hat{\mathbf{r}}, \hat{\mathbf{r}}] = [\hat{\boldsymbol{\theta}}, \hat{\boldsymbol{\theta}}] = [\hat{\boldsymbol{\phi}}, \hat{\boldsymbol{\phi}}] = \mathbf{0}, \quad (60)$$

so  $c_{rr}^\alpha = c_{\theta\theta}^\alpha = c_{\phi\phi}^\alpha = 0$ , where  $\alpha = r, \theta, \phi$ . Also

$$[\hat{\mathbf{r}}, \hat{\boldsymbol{\theta}}] = -[\hat{\boldsymbol{\theta}}, \hat{\mathbf{r}}] = \nabla_r \hat{\boldsymbol{\theta}} - \nabla_\theta \hat{\mathbf{r}} = \mathbf{0} - \frac{1}{r} \hat{\boldsymbol{\theta}} = -\frac{1}{r} \hat{\boldsymbol{\theta}}, \quad (61)$$

so  $c_{r\theta}^\theta = -c_{\theta r}^\theta = -\frac{1}{r}$ ,  $c_{r\theta}^r = c_{\theta r}^r = 0$ . Finally,

$$[\hat{\mathbf{r}}, \hat{\boldsymbol{\phi}}] = [\hat{\boldsymbol{\theta}}, \hat{\boldsymbol{\phi}}] = \mathbf{0}. \quad (62)$$

Summarizing,

$$c^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (63)$$

$$c^\theta = \begin{bmatrix} 0 & -\frac{1}{r} & 0 \\ \frac{1}{r} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (64)$$

$$c^\phi = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \quad (65)$$

Time DERIVATIVES of the VECTOR are

$$\dot{\mathbf{r}} = \begin{bmatrix} \cos \theta \dot{r} - r \sin \theta \dot{\theta} \\ \sin \theta \dot{r} + r \cos \theta \dot{\theta} \\ \dot{z} \end{bmatrix} = \dot{r} \hat{\mathbf{r}} + r \dot{\theta} \hat{\boldsymbol{\theta}} + \dot{z} \hat{\mathbf{z}} \quad (66)$$

$$\begin{aligned} \ddot{\mathbf{r}} &= \begin{bmatrix} -\sin \theta \dot{r} \dot{\theta} + \cos \theta \ddot{r} - \sin \theta \ddot{\theta} - r \cos \theta \dot{\theta}^2 - r \sin \theta \ddot{\theta} \\ \cos \theta \dot{r} \dot{\theta} + \sin \theta \ddot{r} + \cos \theta \ddot{\theta} - r \sin \theta \dot{\theta}^2 + r \cos \theta \ddot{\theta} \\ \ddot{z} \end{bmatrix} \\ &= \begin{bmatrix} -2 \sin \theta \dot{r} \dot{\theta} + \cos \theta \ddot{r} - r \cos \theta \dot{\theta}^2 - r \sin \theta \ddot{\theta} \\ 2 \cos \theta \dot{r} \dot{\theta} + \sin \theta \ddot{r} - r \sin \theta \dot{\theta}^2 + r \cos \theta \ddot{\theta} \\ \ddot{z} \end{bmatrix} \\ &= (\ddot{r} - r \dot{\theta}^2) \hat{\mathbf{r}} + (2 \dot{r} \dot{\theta} + r \ddot{\theta}) \hat{\boldsymbol{\theta}} + \ddot{z} \hat{\mathbf{z}}. \end{aligned} \quad (67)$$

SPEED is given by

$$v \equiv |\dot{\mathbf{r}}| = \sqrt{\dot{r}^2 + r^2 \dot{\theta}^2 + \dot{z}^2}. \quad (68)$$

Time derivatives of the unit VECTORS are

$$\dot{\hat{\mathbf{r}}} = \begin{bmatrix} -\sin \theta \dot{\theta} \\ \cos \theta \dot{\theta} \\ 0 \end{bmatrix} = \dot{\theta} \hat{\boldsymbol{\theta}} \quad (69)$$

$$\dot{\hat{\boldsymbol{\theta}}} = \begin{bmatrix} -\cos \theta \dot{\theta} \\ -\sin \theta \dot{\theta} \\ 0 \end{bmatrix} = -\dot{\theta} \hat{\mathbf{r}} \quad (70)$$

$$\dot{\hat{\mathbf{z}}} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} = \mathbf{0}. \quad (71)$$

CROSS PRODUCTS of the axes are

$$\hat{\mathbf{r}} \times \hat{\mathbf{z}} = -\hat{\boldsymbol{\theta}} \quad (72)$$

$$\hat{\boldsymbol{\theta}} \times \hat{\mathbf{z}} = \hat{\mathbf{r}} \quad (73)$$

$$\hat{\mathbf{r}} \times \hat{\boldsymbol{\theta}} = \hat{\mathbf{z}}. \quad (74)$$

The CONVECTIVE DERIVATIVE is

$$\frac{D\mathbf{r}}{Dt} \equiv \left( \frac{\partial}{\partial t} + \dot{\mathbf{r}} \cdot \nabla \right) \mathbf{r} = \frac{\partial \mathbf{r}}{\partial t} + \dot{\mathbf{r}} \cdot \nabla \mathbf{r}. \quad (75)$$

To rewrite this, use the identity

$$\nabla(\mathbf{A} \cdot \mathbf{B}) = \mathbf{A} \times (\nabla \times \mathbf{B}) + \mathbf{B} \times (\nabla \times \mathbf{A}) + (\mathbf{A} \cdot \nabla) \mathbf{B} + (\mathbf{B} \cdot \nabla) \mathbf{A} \quad (76)$$

and set  $\mathbf{A} = \mathbf{B}$ , to obtain

$$\nabla(\mathbf{A} \cdot \mathbf{A}) = 2\mathbf{A} \times (\nabla \times \mathbf{A}) + 2(\mathbf{A} \cdot \nabla) \mathbf{A}, \quad (77)$$

so

$$(\mathbf{A} \cdot \nabla) \mathbf{A} = \nabla(\frac{1}{2} \mathbf{A}^2) - \mathbf{A} \times (\nabla \times \mathbf{A}). \quad (78)$$

Then

$$\frac{D\mathbf{r}}{Dt} = \ddot{\mathbf{r}} + \nabla(\frac{1}{2} \dot{\mathbf{r}}^2) - \dot{\mathbf{r}} \times (\nabla \times \dot{\mathbf{r}}) = \ddot{\mathbf{r}} + (\nabla \times \dot{\mathbf{r}}) \times \dot{\mathbf{r}} + \nabla(\frac{1}{2} \dot{\mathbf{r}}^2). \quad (79)$$

The CURL in the above expression gives

$$\nabla \times \dot{\mathbf{r}} = \frac{1}{r} \frac{\partial}{\partial r} (r^2 \dot{\boldsymbol{\theta}}) \hat{\mathbf{z}} = 2\dot{\boldsymbol{\theta}} \hat{\mathbf{z}}, \quad (80)$$

so

$$\begin{aligned} -\dot{\mathbf{r}} \times (\nabla \times \dot{\mathbf{r}}) &= -2\dot{\boldsymbol{\theta}} (\dot{\mathbf{r}} \times \hat{\mathbf{z}} + r\dot{\boldsymbol{\theta}} \hat{\boldsymbol{\theta}} \times \hat{\mathbf{z}}) \\ &= -2\dot{\boldsymbol{\theta}} (-\dot{\mathbf{r}} \hat{\boldsymbol{\theta}} + r\dot{\boldsymbol{\theta}} \hat{\mathbf{r}}) = 2\dot{\mathbf{r}} \dot{\boldsymbol{\theta}} \hat{\boldsymbol{\theta}} - 2r\dot{\boldsymbol{\theta}}^2 \hat{\mathbf{r}}. \end{aligned} \quad (81)$$

We expect the gradient term to vanish since SPEED does not depend on position. Check this using the identity  $\nabla(f^2) = 2f\nabla f$ ,

$$\nabla(\frac{1}{2} \dot{\mathbf{r}}^2) = \frac{1}{2} \nabla(\dot{\mathbf{r}}^2 + r^2 \dot{\boldsymbol{\theta}}^2 + \dot{\mathbf{z}}^2) = \dot{\mathbf{r}} \nabla \dot{\mathbf{r}} + r\dot{\boldsymbol{\theta}} \nabla(r\dot{\boldsymbol{\theta}}) + \dot{\mathbf{z}} \nabla \dot{\mathbf{z}}. \quad (82)$$

Examining this term by term,

$$\dot{\mathbf{r}} \nabla \dot{\mathbf{r}} = \dot{\mathbf{r}} \frac{\partial}{\partial t} \nabla r = \dot{\mathbf{r}} \frac{\partial}{\partial t} \hat{\mathbf{r}} = \dot{\mathbf{r}} \hat{\boldsymbol{\theta}} = \dot{\mathbf{r}} \hat{\boldsymbol{\theta}} \quad (83)$$

$$\begin{aligned} r\dot{\boldsymbol{\theta}} \nabla(r\dot{\boldsymbol{\theta}}) &= r\dot{\boldsymbol{\theta}} \left[ r \frac{\partial}{\partial t} \nabla \boldsymbol{\theta} + \dot{\boldsymbol{\theta}} \nabla r \right] = r\dot{\boldsymbol{\theta}} \left[ r \frac{\partial}{\partial t} \left( \frac{1}{r} \hat{\boldsymbol{\theta}} \right) + \dot{\boldsymbol{\theta}} \hat{\mathbf{r}} \right] \\ &= r\dot{\boldsymbol{\theta}} \left[ r \left( -\frac{1}{r^2} \dot{\mathbf{r}} \hat{\boldsymbol{\theta}} + \frac{1}{r} \dot{\boldsymbol{\theta}} \right) + \dot{\boldsymbol{\theta}} \hat{\mathbf{r}} \right] \\ &= -\dot{\boldsymbol{\theta}} \hat{\boldsymbol{\theta}} + r\dot{\boldsymbol{\theta}} (-\dot{\boldsymbol{\theta}} \hat{\mathbf{r}}) + r\dot{\boldsymbol{\theta}}^2 \hat{\mathbf{r}} = -\dot{\boldsymbol{\theta}} \hat{\boldsymbol{\theta}} \end{aligned} \quad (84)$$

$$\dot{\mathbf{z}} \nabla \dot{\mathbf{z}} = \dot{\mathbf{z}} \frac{\partial}{\partial t} \nabla z = \dot{\mathbf{z}} \frac{\partial}{\partial t} \hat{\mathbf{z}} = \dot{\mathbf{z}} \hat{\mathbf{z}} = \mathbf{0}, \quad (85)$$

so, as expected,

$$\nabla(\frac{1}{2} \dot{\mathbf{r}}^2) = \mathbf{0}. \quad (86)$$

We have already computed  $\ddot{\mathbf{r}}$ , so combining all three pieces gives

$$\begin{aligned} \frac{D\mathbf{r}}{Dt} &= (\ddot{r} - r\dot{\boldsymbol{\theta}}^2 - 2r\dot{\boldsymbol{\theta}}\dot{\boldsymbol{\theta}}) \hat{\mathbf{r}} + (2\dot{r}\dot{\boldsymbol{\theta}} + 2\dot{\mathbf{r}}\dot{\boldsymbol{\theta}} + r\ddot{\boldsymbol{\theta}}) \hat{\boldsymbol{\theta}} + \ddot{\mathbf{z}} \hat{\mathbf{z}} \\ &= (\ddot{r} - 3r\dot{\boldsymbol{\theta}}^2) \hat{\mathbf{r}} + (4\dot{r}\dot{\boldsymbol{\theta}} + r\ddot{\boldsymbol{\theta}}) \hat{\boldsymbol{\theta}} + \ddot{\mathbf{z}} \hat{\mathbf{z}}. \end{aligned} \quad (87)$$

The DIVERGENCE is

$$\begin{aligned} \nabla \cdot \mathbf{A} &= A_{r,r}^r = A_{r,r}^r + (\Gamma_{rr}^r A^r + \Gamma_{\theta r}^r A^\theta + \Gamma_{zr}^r A^z) + A_{,\theta}^\theta \\ &\quad + (\Gamma_{r\theta}^\theta A^r + \Gamma_{\theta\theta}^\theta A^\theta + \Gamma_{z\theta}^\theta A^z) \\ &\quad + A_{,z}^z + (\Gamma_{rz}^z A^r + \Gamma_{\theta z}^z A^\theta + \Gamma_{zz}^z A^z) \\ &= A_{r,r}^r + A_{,\theta}^\theta + A_{,z}^z + (0 + 0 + 0) + \left( \frac{1}{r} + 0 + 0 \right) \\ &\quad + (0 + 0 + 0) \\ &= \frac{1}{r} \frac{\partial}{\partial r} A^r + \frac{1}{r} \frac{\partial}{\partial \theta} A^\theta + \frac{1}{r} \frac{\partial}{\partial z} A^z + \frac{1}{r} A^r \\ &= \left( \frac{\partial}{\partial r} + \frac{1}{r} \right) A^r + \frac{1}{r} \frac{\partial}{\partial \theta} A^\theta + \frac{\partial}{\partial z} A^z, \end{aligned} \quad (88)$$

or, in VECTOR notation

$$\nabla \cdot \mathbf{F} = \frac{1}{r} \frac{\partial}{\partial r} (r F_r) + \frac{1}{r} \frac{\partial F_\theta}{\partial \theta} + \frac{\partial F_z}{\partial z}. \quad (89)$$

The CROSS PRODUCT is

$$\begin{aligned} \nabla \times \mathbf{F} &= \left( \frac{1}{r} \frac{\partial F_z}{\partial \theta} - \frac{\partial F_\theta}{\partial z} \right) \hat{\mathbf{r}} + \left( \frac{\partial F_r}{\partial z} - \frac{\partial F_z}{\partial r} \right) \hat{\boldsymbol{\theta}} \\ &\quad + \frac{1}{r} \left[ \frac{\partial}{\partial r} (r F_\theta) - \frac{\partial F_r}{\partial \theta} \right] \hat{\mathbf{z}}, \end{aligned} \quad (90)$$

and the LAPLACIAN is

$$\begin{aligned} \nabla^2 f &\equiv \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial f}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2 f}{\partial \theta^2} + \frac{\partial^2 f}{\partial z^2} \\ &= \frac{\partial^2 f}{\partial r^2} + \frac{1}{r} \frac{\partial f}{\partial r} + \frac{1}{r^2} \frac{\partial^2 f}{\partial \theta^2} + \frac{\partial^2 f}{\partial z^2}. \end{aligned} \quad (91)$$

The vector LAPLACIAN is

$$\nabla^2 \mathbf{v} = \left[ \begin{aligned} &\frac{\partial^2 v_r}{\partial r^2} + \frac{1}{r^2} \frac{\partial^2 v_r}{\partial \phi^2} + \frac{\partial^2 v_r}{\partial z^2} + \frac{1}{r} \frac{\partial v_r}{\partial r} - \frac{2}{r^2} \frac{\partial v_\phi}{\partial \theta} - \frac{v_r}{r^2} \\ &\frac{\partial^2}{\partial r^2} + \frac{1}{r^2} \frac{\partial^2 v_\phi}{\partial \phi^2} + \frac{\partial^2 v_\phi}{\partial z^2} + \frac{1}{r} \frac{\partial v_\phi}{\partial r} + \frac{2}{r^2} \frac{\partial v_r}{\partial \theta} - \frac{v_\phi}{r^2} \\ &\frac{\partial^2 v_z}{\partial r^2} + \frac{1}{r^2} \frac{\partial^2 v_z}{\partial \phi^2} + \frac{\partial^2 v_z}{\partial z^2} + \frac{1}{r} \frac{\partial v_z}{\partial r} \end{aligned} \right]. \quad (92)$$

The HELMHOLTZ DIFFERENTIAL EQUATION is separable in cylindrical coordinates and has STÄCKEL DETERMINANT  $S = 1$  (for  $r, \theta, z$ ) or  $S = 1/(1 - \xi_2^2)$  (for Morse and Feshbach's  $\xi_1, \xi_2, \xi_3$ ).

**Cylindrical Equal-Area Projection**

The MAP PROJECTION having transformation equations,

$$x = (\lambda - \lambda_0) \cos \phi_s \quad (1)$$

$$y = \frac{\sin \phi}{\cos \phi_s} \quad (2)$$

for the normal aspect, and inverse transformation equations

$$\phi = \sin^{-1}(y \cos \phi_s) \quad (3)$$

$$\lambda = \frac{x}{\cos \phi_s} + \lambda_0. \quad (4)$$

An oblique form of the cylindrical equal-area projection is given by the equations

$$\lambda_p = \tan^{-1} \left( \frac{\cos \phi_1 \sin \phi_2 \cos \lambda_1 - \sin \phi_1 \cos \phi_2 \cos \lambda_2}{\sin \phi_1 \cos \phi_2 \sin \lambda_2 - \cos \phi_1 \sin \phi_2 \sin \lambda_1} \right) \quad (5)$$

$$\phi_p = \tan^{-1} \left[ -\frac{\cos(\lambda_p - \lambda_1)}{\tan \phi_1} \right], \quad (6)$$

and the inverse FORMULAS are

$$\phi = \sin^{-1}(y \sin \phi_p + \sqrt{1 - y^2} \cos \phi_p \sin x) \quad (7)$$

$$\lambda = \lambda_0 + \tan^{-1} \left( \frac{\sqrt{1 - y^2} \sin \phi_p \sin x - y \cos \phi_p}{\sqrt{1 - y^2} \cos x} \right). \quad (8)$$

A transverse form of the cylindrical equal-area projection is given by the equations

$$x = \cos \phi \sin(\lambda - \lambda_0) \quad (9)$$

$$y = \tan^{-1} \left[ \frac{\tan \phi}{\cos(\lambda - \lambda_0)} \right] - \phi_0, \quad (10)$$

and the inverse FORMULAS are

$$\phi = \sin^{-1}[\sqrt{1 - x^2} \sin(y + \phi_0)] \quad (11)$$

$$\lambda = \lambda_0 + \tan^{-1} \left[ \frac{x}{\sqrt{1 - x^2}} \cos(y + \phi_0) \right]. \quad (12)$$

**Cylindrical Segment**

The solid portion of a CYLINDER below a cutting PLANE which is oriented PARALLEL to the CYLINDER's axis of symmetry. For a CYLINDER of RADIUS  $r$  and length  $L$ , the VOLUME of the cylindrical segment is given by multiplying the AREA of a circular SEGMENT of height  $h$  by  $L$ ,

$$V = Lr^2 \cos^{-1} \left( \frac{r-h}{r} \right) - (r-h)L\sqrt{2rh-h^2}.$$

see also CYLINDRICAL WEDGE, SECTOR, SEGMENT, SPHERICAL SEGMENT

**Cylindrical Wedge**

The solid cut from a CYLINDER by a tilted PLANE passing through a DIAMETER of the base. It is also called a CYLINDRICAL HOOF. Let the height of the wedge be  $h$  and the radius of the CYLINDER from which it is cut  $r$ . Then plugging the points  $(0, -r, 0)$ ,  $(0, r, 0)$ , and  $(r, 0, h)$  into the 3-point equation for a PLANE gives the equation for the plane as

$$hx - rz = 0. \quad (1)$$

Combining with the equation of the CIRCLE which describes the curved part remaining of the cylinder (and

writing  $t = x$ ) then gives the parametric equations of the "tongue" of the wedge as

$$x = t \quad (2)$$

$$y = \pm \sqrt{r^2 - t^2} \quad (3)$$

$$z = \frac{ht}{r} \quad (4)$$

for  $t \in [0, r]$ . To examine the form of the tongue, it needs to be rotated into a convenient plane. This can be accomplished by first rotating the plane of the curve by  $90^\circ$  about the  $x$ -AXIS using the ROTATION MATRIX  $R_x(90^\circ)$  and then by the ANGLE

$$\theta = \tan^{-1} \left( \frac{h}{r} \right) \quad (5)$$

above the  $z$ -AXIS. The transformed plane now rests in the  $xz$ -plane and has parametric equations

$$x = \frac{t\sqrt{h^2 + r^2}}{r} \quad (6)$$

$$z = \pm \sqrt{r^2 - t^2} \quad (7)$$

and is shown below.

The length of the tongue (measured down its middle) is obtained by plugging  $t = r$  into the above equation for  $x$ , which becomes

$$L = \sqrt{h^2 + r^2} \quad (8)$$

(and which follows immediately from the PYTHAGOREAN THEOREM). The VOLUME of the wedge is given by

$$V = \frac{2}{3}r^2h. \quad (9)$$

## Damped Exponential Cosine Integral

$$\int_0^{\infty} e^{-\omega T} \cos(\omega t) d\omega. \quad (1)$$

Integrate by parts with

$$u \equiv e^{-\omega T} \quad dv = \cos(\omega t) d\omega \quad (2)$$

$$du = -Te^{-\omega T} d\omega \quad v = \frac{1}{t} \sin(\omega t), \quad (3)$$

so

$$\begin{aligned} \int e^{-\omega T} \cos(\omega t) d\omega \\ = \frac{1}{t} e^{-\omega t} \sin(\omega t) + \frac{T}{t} \int e^{-\omega T} \sin(\omega t) d\omega. \end{aligned} \quad (4)$$

Now integrate

$$\int e^{-\omega T} \sin(\omega t) d\omega \quad (5)$$

by parts. Let

$$v = e^{-\omega T} \quad dv = \sin(\omega t) d\omega \quad (6)$$

$$du = -Te^{-\omega T} d\omega \quad v = -\frac{1}{t} \cos(\omega t), \quad (7)$$

so

$$\int e^{-\omega t} \sin(\omega t) d\omega = -\frac{1}{t} \cos(\omega t) - \frac{T}{t} \int e^{-\omega T} \cos(\omega t) d\omega \quad (8)$$

and

$$\begin{aligned} \int e^{\omega T} \cos(\omega t) d\omega &= \frac{1}{t} e^{-\omega t} \sin(\omega t) \\ &- \frac{T}{t^2} e^{-\omega t} \cos(\omega t) - \frac{T^2}{t^2} \int e^{-\omega T} \cos(\omega t) d\omega \end{aligned} \quad (9)$$

$$\begin{aligned} \left(1 + \frac{T^2}{t^2}\right) \int e^{-\omega T} \cos(\omega t) d\omega \\ = e^{-\omega T} \left[ \frac{1}{t} \sin(\omega t) - \frac{T}{t^2} \cos(\omega t) \right] \end{aligned} \quad (10)$$

$$\begin{aligned} \frac{t^2 + T^2}{t^2} \int e^{-\omega T} \cos(\omega t) d\omega \\ = \frac{e^{-\omega t}}{t^2} [t \sin(\omega T) - T \cos(\omega t)] \end{aligned} \quad (11)$$

$$\int e^{-\omega T} \cos(\omega t) d\omega = \frac{e^{-\omega T}}{t^2 + T^2} [t \sin(\omega t) - T \cos(\omega T)]. \quad (12)$$

Therefore,

$$\int_0^{\infty} e^{-\omega T} \cos(\omega t) d\omega = 0 + \frac{T}{t^2 + T^2} = \frac{T}{t^2 + T^2}. \quad (13)$$

see also COSINE INTEGRAL, FOURIER TRANSFORM—LORENTZIAN FUNCTION, LORENTZIAN FUNCTION

## Dandelin Spheres

The inner and outer SPHERES TANGENT internally to a CONE and also to a PLANE intersecting the CONE are called Dandelin spheres.

The SPHERES can be used to show that the intersection of the PLANE with the CONE is an ELLIPSE. Let  $\pi$  be a PLANE intersecting a right circular CONE with vertex  $O$  in the curve  $E$ . Call the SPHERES TANGENT to the CONE and the PLANE  $S_1$  and  $S_2$ , and the CIRCLES on which the CIRCLES are TANGENT to the CONE  $R_1$  and  $R_2$ . Pick a line along the CONE which intersects  $R_1$  at  $Q$ ,  $E$  at  $P$ , and  $R_2$  at  $T$ . Call the points on the PLANE where the CIRCLES are TANGENT  $F_1$  and  $F_2$ . Because intersecting tangents have the same length,

$$F_1P = QP$$

$$F_2P = TP.$$

Therefore,

$$PF_1 + PF_2 = QP + PT = QT,$$

which is a constant independent of  $P$ , so  $E$  is an ELLIPSE with  $a = QT/2$ .

**Danielson-Lanczos Lemma**

The DISCRETE FOURIER TRANSFORM of length  $N$  (where  $N$  is EVEN) can be rewritten as the sum of two DISCRETE FOURIER TRANSFORMS, each of length  $N/2$ . One is formed from the EVEN numbered points; the other from the ODD numbered points. Denote the  $k$ th point of the DISCRETE FOURIER TRANSFORM by  $F_n$ . Then

$$\begin{aligned} F_n &= \sum_{k=0}^{N-1} f_k e^{-2\pi i k n / N} \\ &= \sum_{k=0}^{N/2-1} e^{-2\pi i k n / (N/2)} f_{2k} + W^n \sum_{k=0}^{N/2-1} e^{-2\pi i k n / (N/2)} f_{2k+1} \\ &= F_n^e + W^n F_n^o, \end{aligned}$$

where  $W \equiv e^{-2\pi i / N}$  and  $n = 0, \dots, N$ . This procedure can be applied recursively to break up the  $N/2$  even and ODD points to their  $N/4$  EVEN and ODD points. If  $N$  is a POWER of 2, this procedure breaks up the original transform into  $\lg N$  transforms of length 1. Each transform of an individual point has  $F_n^{e e o \dots} = f_k$  for some  $k$ . By reversing the patterns of evens and odds, then letting  $e = 0$  and  $o = 1$ , the value of  $k$  in BINARY is produced. This is the basis for the FAST FOURIER TRANSFORM.

#### Dawson's Integral

An INTEGRAL which arises in computation of the Voigt lineshape:

$$D(x) \equiv e^{-x^2} \int_0^x e^{y^2} dy. \quad (1)$$

It is sometimes generalized such that

$$D_{\pm}(x) \equiv e^{\mp x^2} \int_0^x e^{\pm y^2} dy, \quad (2)$$

giving

$$D_+(x) = \frac{1}{2} \sqrt{\pi} e^{-x^2} \operatorname{erfi}(x) \quad (3)$$

$$D_-(x) = \frac{1}{2} \sqrt{\pi} e^{x^2} \operatorname{erf}(x), \quad (4)$$

where  $\operatorname{erf}(z)$  is the ERF function and  $\operatorname{erfi}(z)$  is the imaginary error function ERFI.  $D_+(x)$  is illustrated in the left figure above, and  $D_-(x)$  in the right figure.  $D_+$  has a maximum at  $D'_+(x) = 0$ , or

$$1 - \sqrt{\pi} e^{-x^2} x^2 \operatorname{erfi}(x) = 0, \quad (5)$$

giving

$$D_+(0.9241388730) = 0.5410442246, \quad (6)$$

and an inflection at  $D''_+(x) = 0$ , or

$$-2x + \sqrt{\pi} e^{-x^2} (2x^2 - 1) \operatorname{erfi}(x) = 0, \quad (7)$$

giving

$$D_+(1.5019752683) = 0.4276866160. \quad (8)$$

#### de Bruijn Constant

Also called the COPSON-DE BRUIJN CONSTANT. It is defined by

$$\sum_{n=1}^{\infty} a_n \leq c \sum_{n=1}^{\infty} \sqrt{\frac{a_n^2 + a_{n+1}^2 + a_{n+2}^2 + \dots}{n}}.$$

where

$$c = 1.0164957714\dots$$

#### de Bruijn-Newman Constant

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let  $\Xi$  be the XI FUNCTION defined by

$$\Xi(iz) = \frac{1}{2} \left( z^2 - \frac{1}{4} \right) \pi^{-z/2 - \frac{1}{4}} \Gamma\left(\frac{1}{2}z + \frac{1}{4}\right) \zeta\left(z + \frac{1}{2}\right). \quad (1)$$

$\Xi(z/2)/8$  can be viewed as the FOURIER TRANSFORM of the signal

$$\Phi(t) = \sum_{n=1}^{\infty} (2\pi^2 n^4 e^{9t} - 3\pi n^2 e^{5t}) e^{-\pi n^2 e^{4t}} \quad (2)$$

for  $t \in \mathbb{R} \geq 0$ . Then denote the FOURIER TRANSFORM of  $\Phi(t)e^{\lambda t^2}$  as  $H(\lambda, z)$ ,

$$\mathcal{F}[\Phi(t)e^{\lambda t^2}] = H(\lambda, z). \quad (3)$$

de Bruijn (1950) proved that  $H$  has only REAL zeros for  $\lambda \geq 1/2$ . C. M. Newman (1976) proved that there exists a constant  $\Lambda$  such that  $H$  has only REAL zeros IFF  $\lambda \geq \Lambda$ . The best current lower bound (Csordas *et al.* 1993, 1994) is  $\Lambda > -5.895 \times 10^{-9}$ . The RIEMANN HYPOTHESIS is equivalent to the conjecture that  $\Lambda \leq 0$ .

**de Bruijn Sequence**

The shortest sequence such that every string of length  $n$  on the ALPHABET  $a$  occurs as a contiguous subrange of the sequence described by  $a$ . Every de Bruijn sequence corresponds to an EULERIAN CYCLE on a "DE BRUIJN GRAPH." Surprisingly, it turns out that the lexicographic sequence of LYNDON WORDS of lengths DIVISIBLE by  $n$  gives the lexicographically smallest de Bruijn sequence (Ruskey).

**de Mere's Problem**

The probability of getting at least one "6" in four rolls of a single 6-sided DIE is

$$1 - \left(\frac{5}{6}\right)^4 = 0.518 \dots, \quad (1)$$

which is slightly higher than the probability of at least one double 6 in 24 throws,

$$1 - \left(\frac{35}{36}\right)^{24} = 0.491 \dots \quad (2)$$

de Mere suspected that (1) was higher than (2). He posed the question to Pascal, who solved the problem and proved de Mere correct.

**References**

Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, 1996.

**de Moivre-Laplace Theorem**

The sum of those terms of the BINOMIAL SERIES of  $(p+q)^s$  for which the number of successes  $x$  falls between  $d_1$  and  $d_2$  is approximately

$$Q \approx \frac{1}{\sqrt{2\pi}} \int_{t_1}^{t_2} e^{-t^2/2} dt, \quad (1)$$

where

$$t_1 \equiv \frac{d_1 - \frac{1}{2} - sp}{\sigma} \quad (2)$$

$$t_2 \equiv \frac{d_2 + \frac{1}{2} - sp}{\sigma} \quad (3)$$

$$\sigma \equiv \sqrt{spq}. \quad (4)$$

Uspensky (1937) has shown that

$$Q = \frac{1}{\sqrt{2\pi}} \int_{t_1}^{t_2} e^{-t^2/2} dt + \frac{q-p}{6\sigma} \left[ (1-t^2) \frac{1}{2\pi} e^{-t^2/2} \right]_{t_1}^{t_2} + \Omega, \quad (5)$$

where

$$|\Omega| < \frac{0.12 + 0.18|p-q|}{\sigma^2} + e^{-3\sigma/2} \quad (6)$$

for  $\sigma \geq 5$ .

A COROLLARY states that the probability that  $x$  successes in  $s$  trials will differ from the expected value  $sp$  by more than  $d$  is

$$P_\delta \approx 1 - 2 \int_0^\delta \phi(t) dt, \quad (7)$$

where

$$\delta \equiv \frac{d + \frac{1}{2}}{\sigma}. \quad (8)$$

Uspensky (1937) showed that

$$Q_{\delta_1} \equiv P(|x - sp| \leq d) = 2 \int_0^{\delta_1} \phi(t) dt + \frac{1 - \theta_1 - \theta_2}{\sigma} \phi(\delta_1) + \Omega_1, \quad (9)$$

where

$$\delta_1 \equiv \frac{d}{\sigma} \quad (10)$$

$$\theta_1 \equiv (sq + d) - [sq + d] \quad (11)$$

$$\theta_2 \equiv (sp + d) - [sp + d] \quad (12)$$

and

$$|\Omega_1| < \frac{0.20 + 0.25|p-q|}{\sigma^2} + e^{-3\sigma/2}, \quad (13)$$

for  $\sigma \geq 5$ .

**de Rham Cohomology**

de Rham cohomology is a formal set-up for the analytic problem: If you have a DIFFERENTIAL  $k$ -FORM  $\omega$  on a MANIFOLD  $M$ , is it the EXTERIOR DERIVATIVE of another DIFFERENTIAL  $k$ -FORM  $\omega'$ ? Formally, if  $\omega = d\omega'$  then  $d\omega = 0$ . This is more commonly stated as  $d \circ d = 0$ , meaning that if  $\omega$  is to be the EXTERIOR DERIVATIVE of a DIFFERENTIAL  $k$ -FORM, a NECESSARY condition that  $\omega$  must satisfy is that its EXTERIOR DERIVATIVE is zero.

de Rham cohomology gives a formalism that aims to answer the question, "Are all differential  $k$ -forms on a MANIFOLD with zero EXTERIOR DERIVATIVE the EXTERIOR DERIVATIVES of  $(k+1)$ -forms?" In particular, the  $k$ th de Rham cohomology vector space is defined to be the space of all  $k$ -forms with EXTERIOR DERIVATIVE 0, modulo the space of all boundaries of  $(k+1)$ -forms. This is the trivial VECTOR SPACE IFF the answer to our question is yes.

The fundamental result about de Rham cohomology is that it is a topological invariant of the MANIFOLD, namely: the  $k$ th de Rham cohomology VECTOR SPACE of a MANIFOLD  $M$  is canonically isomorphic to the ALEXANDER-SPANIER COHOMOLOGY VECTOR SPACE  $H^k(M; \mathbb{R})$  (also called cohomology with compact support). In the case that  $M$  is compact, ALEXANDER-SPANIER COHOMOLOGY is exactly singular cohomology. *see also* ALEXANDER-SPANIER COHOMOLOGY, CHANGE OF VARIABLES THEOREM, DIFFERENTIAL  $k$ -FORM, EXTERIOR DERIVATIVE, VECTOR SPACE

**Decimal Expansion**

The decimal expansion of a number is its representation in base 10. For example, the decimal expansion of  $25^2$  is 625, of  $\pi$  is 3.14159..., and of  $1/9$  is 0.1111....

If  $r \equiv p/q$  has a finite decimal expansion, then

$$\begin{aligned} r &= \frac{a_1}{10} + \frac{a_2}{10^2} + \dots + \frac{a_n}{10^n} \\ &= \frac{a_1 10^{n-1} + a_2 10^{n-2} + \dots + a_n}{10^n} \\ &= \frac{a_1 10^{n-1} + a_2 10^{n-2} + \dots + a_n}{2^n 5^n}. \end{aligned} \quad (1)$$

FACTORING possible common multiples gives

$$r = \frac{p}{2^\alpha 5^\beta}, \quad (2)$$

where  $p \not\equiv 0 \pmod{2, 5}$ . Therefore, the numbers with finite decimal expansions are fractions of this form. The number of decimals is given by  $\max(\alpha, \beta)$ . Numbers which have a finite decimal expansion are called REGULAR NUMBERS.

Any NONREGULAR fraction  $m/n$  is periodic, and has a period  $\lambda(n)$  independent of  $m$ , which is at most  $n - 1$  DIGITS long. If  $n$  is RELATIVELY PRIME to 10, then the period of  $m/n$  is a divisor of  $\phi(n)$  and has at most  $\phi(n)$  DIGITS, where  $\phi$  is the TOTIENT FUNCTION. When a rational number  $m/n$  with  $(m, n) = 1$  is expanded, the period begins after  $s$  terms and has length  $t$ , where  $s$  and  $t$  are the smallest numbers satisfying

$$10^2 \equiv 10^{s+t} \pmod{n}. \quad (3)$$

When  $n \not\equiv 0 \pmod{2, 5}$ ,  $s = 0$ , and this becomes a purely periodic decimal with

$$10^t \equiv 1 \pmod{n}. \quad (4)$$

As an example, consider  $n = 84$ .

$$\begin{aligned} 10^0 &\equiv 1 & 10^1 &\equiv 10 & 10^2 &\equiv 16 & 10^3 &\equiv -8 \\ 10^4 &\equiv 4 & 10^5 &\equiv 40 & 10^6 &\equiv -20 & 10^7 &\equiv -32, \\ 10^8 &\equiv 16 \end{aligned}$$

so  $s = 2$ ,  $t = 6$ . The decimal representation is  $1/84 = 0.0119047\bar{6}$ . When the DENOMINATOR of a fraction  $m/n$  has the form  $n = n_0 2^\alpha 5^\beta$  with  $(n_0, 10) = 1$ , then the period begins after  $\max(\alpha, \beta)$  terms and the length of the period is the exponent to which 10 belongs (mod  $n_0$ ), i.e., the number  $x$  such that  $10^x \equiv 1 \pmod{n_0}$ . If  $q$  is PRIME and  $\lambda(q)$  is EVEN, then breaking the repeating DIGITS into two equal halves and adding gives all 9s. For example,  $1/7 = 0.14285\bar{7}$ , and  $142 + 857 = 999$ . For  $1/q$  with a PRIME DENOMINATOR other than 2 or 5, all cycles  $n/q$  have the same length (Conway and Guy 1996).

If  $n$  is a PRIME and 10 is a PRIMITIVE ROOT of  $n$ , then the period  $\lambda(n)$  of the repeating decimal  $1/n$  is given by

$$\lambda(n) = \phi(n), \quad (5)$$

where  $\phi(n)$  is the TOTIENT FUNCTION. Furthermore, the decimal expansions for  $p/n$ , with  $p = 1, 2, \dots, n-1$  have periods of length  $n-1$  and differ only by a cyclic permutation. Such numbers are called LONG PRIMES by Conway and Guy (1996). An equivalent definition is that

$$10^i \equiv 1 \pmod{n} \quad (6)$$

for  $i = n-1$  and no  $i$  less than this. In other words, a NECESSARY (but not SUFFICIENT) condition is that the number  $9R_{n-1}$  (where  $R_n$  is a REPUNIT) is DIVISIBLE by  $n$ , which means that  $R_n$  is DIVISIBLE by  $n$ .

The first few numbers with maximal decimal expansions, called FULL REPTEND PRIMES, are 7, 17, 19, 23, 29, 47, 59, 61, 97, 109, 113, 131, 149, 167, ... (Sloane's A001913). The decimals corresponding to these are called CYCLIC NUMBERS. No general method is known for finding FULL REPTEND PRIMES. Artin conjectured that ARTIN'S CONSTANT  $C = 0.3739558136\dots$  is the fraction of PRIMES  $p$  for which  $1/p$  has decimal maximal period (Conway and Guy 1996). D. Lehmer has generalized this conjecture to other bases, obtaining values which are small rational multiples of  $C$ .

To find DENOMINATORS with short periods, note that

$$\begin{aligned} 10^1 - 1 &= 3^2 \\ 10^2 - 1 &= 3^2 \cdot 11 \\ 10^3 - 1 &= 3^3 \cdot 37 \\ 10^4 - 1 &= 3^2 \cdot 11 \cdot 101 \\ 10^5 - 1 &= 3^2 \cdot 41 \cdot 271 \\ 10^6 - 1 &= 3^3 \cdot 7 \cdot 11 \cdot 13 \cdot 37 \\ 10^7 - 1 &= 3^2 \cdot 239 \cdot 4649 \\ 10^8 - 1 &= 3^2 \cdot 11 \cdot 73 \cdot 101 \cdot 137 \\ 10^9 - 1 &= 3^4 \cdot 37 \cdot 333667 \\ 10^{10} - 1 &= 3^2 \cdot 11 \cdot 41 \cdot 271 \cdot 9091 \\ 10^{11} - 1 &= 3^2 \cdot 21649 \cdot 513239 \\ 10^{12} - 1 &= 3^3 \cdot 7 \cdot 11 \cdot 13 \cdot 37 \cdot 101 \cdot 9901. \end{aligned}$$

The period of a fraction with DENOMINATOR equal to a PRIME FACTOR above is therefore the POWER of 10 in which the factor first appears. For example, 37 appears in the factorization of  $10^3 - 1$  and  $10^9 - 1$ , so its period is 3. Multiplication of any FACTOR by a  $2^\alpha 5^\beta$  still gives the same period as the FACTOR alone. A DENOMINATOR obtained by a multiplication of two FACTORS has a period equal to the first POWER of 10 in which both FACTORS appear. The following table gives the PRIMES having small periods (Sloane's A046106, A046107, and A046108; Ogilvy and Anderson 1988).

period	primes
1	3
2	11
3	37
4	101
5	41, 271
6	7, 13
7	239, 4649
8	73, 137
9	333667
10	9091
11	21649, 513239
12	9901
13	53, 79, 265371653
14	909091
15	31, 2906161
16	17, 5882353
17	2071723, 5363222357
18	19, 52579
19	111111111111111111
20	3541, 27961

A table of the periods  $e$  of small PRIMES other than the special  $p = 5$ , for which the decimal expansion is not periodic, follows (Sloane's A002371).

$p$	$e$	$p$	$e$	$p$	$e$
3	1	31	15	67	33
7	6	37	3	71	35
11	2	41	5	73	8
13	6	43	21	79	13
17	16	47	46	83	41
19	18	53	13	89	44
23	22	59	58	97	96
29	28	61	60	101	4

Shanks (1873ab) computed the periods for all PRIMES up to 120,000 and published those up to 29,989.

## Decimal Period

see DECIMAL EXPANSION

## Decision Problem

Does there exist an ALGORITHM for deciding whether or not a specific mathematical assertion does or does not have a proof? The decision problem is also known as the ENTSCHEIDUNGSPROBLEM (which, not so coincidentally, is German for "decision problem"). Using the concept of the TURING MACHINE, Turing showed the answer to be NEGATIVE for elementary NUMBER THEORY. J. Robinson and Tarski showed the decision problem is undecidable for arbitrary FIELDS.

## Decision Theory

A branch of GAME THEORY dealing with strategies to maximize the outcome of a given process in the face of uncertain conditions.

see also NEWCOMB'S PARADOX, OPERATIONS RESEARCH, PRISONER'S DILEMMA

## Decomposition

A rewriting of a given quantity (e.g., a MATRIX) in terms of a combination of "simpler" quantities.

see also CHOLESKY DECOMPOSITION, CONNECTED SUM DECOMPOSITION, JACO-SHALEN-JOHANNSON TORUS DECOMPOSITION, LU DECOMPOSITION, QR DECOMPOSITION, SINGULAR VALUE DECOMPOSITION

## Deconvolution

The inversion of a CONVOLUTION equation, i.e., the solution for  $f$  of an equation of the form

$$f * g = h + \epsilon,$$

given  $g$  and  $h$ , where  $\epsilon$  is the NOISE and  $*$  denotes the CONVOLUTION. Deconvolution is ill-posed and will usually not have a unique solution even in the absence of NOISE.

Linear deconvolution ALGORITHMS include INVERSE FILTERING and WIENER FILTERING. Nonlinear ALGORITHMS include the CLEAN ALGORITHM, MAXIMUM ENTROPY METHOD, and LUCY.

see also CLEAN ALGORITHM, CONVOLUTION, LUCY, MAXIMUM ENTROPY METHOD, WIENER FILTER

## Decreasing Function

A function  $f(x)$  decreases on an INTERVAL  $I$  if  $f(b) < f(a)$  for all  $b > a$ , where  $a, b \in I$ . Conversely, a function  $f(x)$  increases on an INTERVAL  $I$  if  $f(b) > f(a)$  for all  $b > a$  with  $a, b \in I$ .

If the DERIVATIVE  $f'(x)$  of a CONTINUOUS FUNCTION  $f(x)$  satisfies  $f'(x) < 0$  on an OPEN INTERVAL  $(a, b)$ , then  $f(x)$  is decreasing on  $(a, b)$ . However, a function may decrease on an interval without having a derivative defined at all points. For example, the function  $-x^{1/3}$  is decreasing everywhere, including the origin  $x = 0$ , despite the fact that the DERIVATIVE is not defined at that point.

see also DERIVATIVE, INCREASING FUNCTION, NONDECREASING FUNCTION, NONINCREASING FUNCTION

## Decreasing Sequence

A SEQUENCE  $\{a_1, a_2, \dots\}$  for which  $a_1 \geq a_2 \geq \dots$

see also INCREASING SEQUENCE

## Decreasing Series

A SERIES  $s_1, s_2, \dots$  for which  $s_1 \geq s_2 \geq \dots$

## Dedekind's Axiom

For every partition of all the points on a line into two nonempty SETS such that no point of either lies between two points of the other, there is a point of one SET which lies between every other point of that SET and every point of the other SET.

### Dedekind Cut

A set partition of the RATIONAL NUMBERS into two nonempty subsets  $S_1$  and  $S_2$  such that all members of  $S_1$  are less than those of  $S_2$  and such that  $S_1$  has no greatest member. REAL NUMBERS can be defined using either Dedekind cuts or CAUCHY SEQUENCES.

see also CANTOR-DEDEKIND AXIOM, CAUCHY SEQUENCE

### Dedekind Eta Function

Let

$$q = e^{2\pi iz}, \quad (1)$$

then the Dedekind eta function is defined by

$$\eta(z) \equiv q^{1/24} \prod_{n=1}^{\infty} (1 - q^n), \quad (2)$$

which can be written as

$$\eta(z) = q^{1/24} \left\{ 1 + \sum_{n=1}^{\infty} (-1)^n [q^{n(3n-1)/2} + q^{n(3n+1)/2}] \right\} \quad (3)$$

(Weber 1902, pp. 85 and 112; Atkin and Morain 1993).  $\eta$  is a MODULAR FORM. Letting  $\zeta_{24} = 2^{2\pi i/24}$  be a ROOT OF UNITY,  $\eta(z)$  satisfies

$$\eta(z+1) = \zeta_{24} \eta(z) \quad (4)$$

$$\eta\left(-\frac{1}{z}\right) = -\sqrt{z}i \eta(z) \quad (5)$$

(Weber 1902, p. 113; Atkin and Morain 1993).

### Dedekind Function

$$\psi(n) = n \prod_{\substack{\text{distinct prime} \\ \text{factors } p \text{ of } n}} (1 + p^{-1}),$$

where the PRODUCT is over the distinct PRIME FACTORS of  $n$ . The first few values are 1, 3, 4, 6, 6, 12, 8, 12, 12, 18, ... (Sloane's A001615).

### Dedekind's Problem

The determination of the number of monotone BOOLEAN FUNCTIONS of  $n$  variables is called Dedekind's problem.

### Dedekind Ring

A abstract commutative RING in which every NONZERO IDEAL is a unique product of PRIME IDEALS.

### Dedekind Sum

Given RELATIVELY PRIME INTEGERS  $p$  and  $q$ , the Dedekind sum is defined by

$$s(p, q) \equiv \sum_{i=1}^q \left( \left( \frac{i}{q} \right) \right) \left( \left( \frac{pi}{q} \right) \right), \quad (1)$$

where

$$((x)) \equiv \begin{cases} x - [x] - \frac{1}{2} & x \in \mathbb{Z} \\ 0 & x \notin \mathbb{Z}. \end{cases} \quad (2)$$

Dedekind sums obey 2-term

$$s(p, q) + s(q, p) = -\frac{1}{4} + \frac{1}{12} \left( \frac{p}{q} + \frac{q}{p} + \frac{1}{pq} \right), \quad (3)$$

and 3-term

$$s(bc', a) + s(ca', b) + s(ab', c) = -\frac{1}{4} + \frac{1}{12} \left( \frac{a}{bc} + \frac{b}{ca} + \frac{c}{ab} \right) \quad (4)$$

reciprocity laws, where  $a, b, c$  are pairwise COPRIME and

$$aa' \equiv 1 \pmod{b} \quad (5)$$

$$bb' \equiv 1 \pmod{c} \quad (6)$$

$$cc' \equiv 1 \pmod{a}. \quad (7)$$

Let  $p, q, u, v \in \mathbb{N}$  with  $(p, q) = (u, v) = 1$  (i.e., are pairwise RELATIVELY PRIME), then the Dedekind sums also satisfy

$$s(p, q) + s(u, v) = s(pu' - qv', pv + qu) - \frac{1}{4} + \frac{1}{12} \left( \frac{q}{vt} + \frac{v}{tq} + \frac{t}{qv} \right), \quad (8)$$

where  $t = pv + qu$ , and  $u', v'$  are any INTEGERS such that  $uu' + vv' = 1$  (Pommersheim 1993).

#### References

Pommersheim, J. "Toric Varieties, Lattice Points, and Dedekind Sums." *Math. Ann.* **295**, 1–24, 1993.

### Deducible

If  $q$  is logically deducible from  $p$ , this is written  $p \vdash q$ .

### Deep Theorem

Qualitatively, a deep theorem is a theorem whose proof is long, complicated, difficult, or appears to involve branches of mathematics which are not obviously related to the theorem itself (Shanks 1993). Shanks (1993) cites the QUADRATIC RECIPROCITY THEOREM as an example of a deep theorem.

see also THEOREM

#### References

Shanks, D. "Is the Quadratic Reciprocity Law a Deep Theorem?" §2.25 in *Solved and Unsolved Problems in Number Theory*, 4th ed. New York: Chelsea, pp. 64–66, 1993.

### Defective Matrix

A MATRIX whose EIGENVECTORS are not COMPLETE.

### Defective Number

see DEFICIENT NUMBER

### Deficiency

The deficiency of a BINOMIAL COEFFICIENT  $\binom{n+k}{k}$  with  $k \leq n$  as the number of  $i$  for which  $b_i = 1$ , where

$$n + i = a_i b_i,$$

$1 \leq i \leq k$ , the PRIME factors of  $b_i$  are  $> k$ , and  $\prod a_i = k!$ , where  $k!$  is the FACTORIAL.

see also ABUNDANCE

#### References

Guy, R. K. *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 84–85, 1994.

### Deficient Number

Numbers which are not PERFECT and for which

$$s(N) \equiv \sigma(N) - N < N,$$

or equivalently

$$\sigma(n) < 2n,$$

where  $\sigma(N)$  is the DIVISOR FUNCTION. Deficient numbers are sometimes called DEFECTIVE NUMBERS (Singh 1997). PRIMES, POWERS of PRIMES, and any divisors of a PERFECT or deficient number are all deficient. The first few deficient numbers are 1, 2, 3, 4, 5, 7, 8, 9, 10, 11, 13, 14, 15, 16, 17, 19, 21, 22, 23, ... (Sloane's A002855). see also ABUNDANT NUMBER, LEAST DEFICIENT NUMBER, PERFECT NUMBER

### Definable Set

An ANALYTIC, BOREL, or COANALYTIC SET.

### Defined

If  $A$  and  $B$  are equal by definition (i.e.,  $A$  is defined as  $B$ ), then this is written symbolically as  $A \equiv B$  or  $A := B$ .

### Definite Integral

An INTEGRAL

$$\int_a^b f(x) dx$$

with upper and lower limits. The first FUNDAMENTAL THEOREM OF CALCULUS allows definite integrals to be computed in terms of INDEFINITE INTEGRALS, since if  $F$  is the INDEFINITE INTEGRAL for  $f(x)$ , then

$$\int_a^b f(x) dx = F(b) - F(a).$$

see also CALCULUS, FUNDAMENTAL THEOREMS OF CALCULUS, INDEFINITE INTEGRAL, INTEGRAL

**Degenerate**

A limiting case in which a class of object changes its nature so as to belong to another, usually simpler, class. For example, the POINT is a degenerate case of the CIRCLE as the RADIUS approaches 0, and the CIRCLE is a degenerate form of an ELLIPSE as the ECCENTRICITY approaches 0. Another example is the two identical ROOTS of the second-order POLYNOMIAL  $(x-1)^2$ . Since the  $n$  ROOTS of an  $n$ th degree POLYNOMIAL are usually distinct, ROOTS which coincide are said to be degenerate. Degenerate cases often require special treatment in numerical and analytical solutions. For example, a simple search for both ROOTS of the above equation would find only a single one: 1

The word degenerate also has several very specific and technical meanings in different branches of mathematics.

**References**

Arfken, G. *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 513–514, 1985.

**Degree**

The word “degree” has many meanings in mathematics. The most common meaning is the unit of ANGLE measure defined such that an entire rotation is  $360^\circ$ . This unit harks back to the Babylonians, who used a base 60 number system.  $360^\circ$  likely arises from the Babylonian year, which was composed of 360 days (12 months of 30 days each). The degree is subdivided into 60 MINUTES per degree, and 60 SECONDS per MINUTE.

see also ARC MINUTE, ARC SECOND, DEGREE OF FREEDOM, DEGREE (MAP), DEGREE (POLYNOMIAL), DEGREE (VERTEX), INDEGREE, LOCAL DEGREE, OUT-DEGREE

**Degree (Algebraic Surface)**

see ORDER (ALGEBRAIC SURFACE)

**Degree of Freedom**

The number of degrees of freedom in a problem, distribution, etc., is the number of parameters which may be independently varied.

see also LIKELIHOOD RATIO

**Degree (Map)**

Let  $f : M \mapsto N$  be a MAP between two compact, connected, oriented  $n$ -D MANIFOLDS without boundary. Then  $f$  induces a HOMEOMORPHISM  $f_*$  from the HOMOLOGY GROUPS  $H_n(M)$  to  $H_n(N)$ , both canonically isomorphic to the INTEGERS, and so  $f_*$  can be thought of as a HOMEOMORPHISM of the INTEGERS. The INTEGER  $d(f)$  to which the number 1 gets sent is called the degree of the MAP  $f$ .

There is an easy way to compute  $d(f)$  if the MANIFOLDS involved are smooth. Let  $x \in N$ , and approximate  $f$  by a smooth map HOMOTOPIC to  $f$  such that  $x$  is a “regular value” of  $f$  (which exist and are everywhere by

SARD’S THEOREM). By the IMPLICIT FUNCTION THEOREM, each point in  $f^{-1}(x)$  has a NEIGHBORHOOD such that  $f$  restricted to it is a DIFFEOMORPHISM. If the DIFFEOMORPHISM is orientation preserving, assign it the number +1, and if it is orientation reversing, assign it the number –1. Add up all the numbers for all the points in  $f^{-1}(x)$ , and that is the  $d(f)$ , the degree of  $f$ . One reason why the degree of a map is important is because it is a HOMOTOPY invariant. A sharper result states that two self-maps of the  $n$ -sphere are homotopic IFF they have the same degree. This is equivalent to the result that the  $n$ th HOMOTOPY GROUP of the  $n$ -SPHERE is the set  $\mathbb{Z}$  of INTEGERS. The ISOMORPHISM is given by taking the degree of any representation.

One important application of the degree concept is that homotopy classes of maps from  $n$ -spheres to  $n$ -spheres are classified by their degree (there is exactly one homotopy class of maps for every INTEGER  $n$ , and  $n$  is the degree of those maps).

**Degree (Polynomial)**

see ORDER (POLYNOMIAL)

**Degree Sequence**

Given an (undirected) GRAPH, a degree sequence is a monotonic nonincreasing sequence of the degrees of its VERTICES. A degree sequence is said to be  $k$ -connected if there exists some  $k$ -CONNECTED GRAPH corresponding to the degree sequence. For example, while the degree sequence  $\{1, 2, 1\}$  is 1- but not 2-connected,  $\{2, 2, 2\}$  is 2-connected. The number of degree sequences for  $n = 1, 2, \dots$  is given by 1, 2, 4, 11, 31, 102, ... (Sloane’s A004251).

**Degree (Vertex)**

see VERTEX DEGREE

**Dehn Invariant**

An invariant defined using the angles of a 3-D POLYHEDRON. It remains constant under solid DISSECTION and reassembly. However, solids with the same volume can have different Dehn invariants. Two POLYHEDRA can be dissected into each other only if they have the same volume and the same Dehn invariant.

see also DISSECTION, EHRHART POLYNOMIAL

**Dehn's Lemma**

If you have an embedding of a 1-SPHERE in a 3-MANIFOLD which exists continuously over the 2-DISK, then it also extends over the DISK as an embedding. It was proposed by Dehn in 1910, but a correct proof was not obtained until the work of Papakyriakopoulos (1957ab).

**Delannoy Number**

The Delannoy numbers are defined by

$$D(a, b) = D(a - 1, b) + D(a, b - 1) + D(a - 1, b - 1),$$

where  $D(0, 0) = 1$ . They are the number of lattice paths from  $(0, 0)$  to  $(b, a)$  in which only east  $(1, 0)$ , north  $(0, 1)$ , and northeast  $(1, 1)$  steps are allowed (i.e.,  $\rightarrow$ ,  $\uparrow$ , and  $\nearrow$ ).

For  $n \equiv a = b$ , the Delannoy numbers are the number of "king walks"

$$D(n, n) = P_n(3),$$

where  $P_n(x)$  is a LEGENDRE POLYNOMIAL (Moser 1955, Vardi 1991). Another expression is

$$D(n, n) = \sum_{k=0}^n \binom{n}{k} \binom{n+k}{k} = {}_2F_1(-n, n+1; 1; -1),$$

where  $\binom{a}{b}$  is a BINOMIAL COEFFICIENT and  ${}_2F_1(a, b; c; z)$  is a HYPERGEOMETRIC FUNCTION. The values of  $D(n, n)$  for  $n = 1, 2, \dots$  are 3, 13, 63, 321, 1683, 8989, 48639, ... (Sloane's A001850).

The SCHRÖDER NUMBERS bear the same relation to the Delannoy numbers as the CATALAN NUMBERS do to the BINOMIAL COEFFICIENTS.

see also BINOMIAL COEFFICIENT, CATALAN NUMBER, MOTZKIN NUMBER, SCHRÖDER NUMBER

**Delaunay Triangulation**

The NERVE of the cells in a VORONOI DIAGRAM, which is the triangular of the CONVEX HULL of the points in the diagram. The Delaunay triangulation of a VORONOI DIAGRAM in  $\mathbb{R}^2$  is the diagram's planar dual.

see also TRIANGULATION

**Delian Constant**

The number  $2^{1/3}$  (the CUBE ROOT of 2) which is to be constructed in the CUBE DUPLICATION problem. This number is not a EUCLIDEAN NUMBER although it is an ALGEBRAIC of third degree.

**References**

- Conway, J. H. and Guy, R. K. "Three Greek Problems." In *The Book of Numbers*. New York: Springer-Verlag, pp. 192–194, 1996.

**Delian Problem**

see CUBE DUPLICATION

**Delta Amplitude**

Given an AMPLITUDE  $\phi$  and a MODULUS  $m$  in an ELLIPTIC INTEGRAL,

$$\Delta(\phi) \equiv \sqrt{1 - m \sin^2 \phi}.$$

see also AMPLITUDE, ELLIPTIC INTEGRAL, MODULUS (ELLIPTIC INTEGRAL)

**Delta Curve**

A curve which can be turned continuously inside an EQUILATERAL TRIANGLE. There are an infinite number of delta curves, but the simplest are the CIRCLE and lens-shaped  $\Delta$ -biangle. All the  $\Delta$  curves of height  $h$  have the same PERIMETER  $2\pi h/3$ . Also, at each position of a  $\Delta$  curve turning in an EQUILATERAL TRIANGLE, the perpendiculars to the sides at the points of contact are CONCURRENT at the instantaneous center of rotation.

see also REULEAUX TRIANGLE

**References**

Honsberger, R. *Mathematical Gems I*. Washington, DC: Math. Assoc. Amer., pp. 56–59, 1973.

**Delta Function**

Defined as the limit of a class of DELTA SEQUENCES. Sometimes called the IMPULSE SYMBOL. The most commonly used (equivalent) definitions are

$$\delta(x) \equiv \lim_{n \rightarrow \infty} \frac{1}{2\pi} \frac{\sin[(n + \frac{1}{2})x]}{\sin(\frac{1}{2}x)} \quad (1)$$

(the so-called DIRICHLET KERNEL) and

$$\delta(x) \equiv \lim_{n \rightarrow \infty} \frac{\sin(nx)}{\pi x} \quad (2)$$

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-ikx} dk \quad (3)$$

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-ikx} dk \quad (4)$$

$$= \mathcal{F}[1], \quad (5)$$

where  $\mathcal{F}$  is the FOURIER TRANSFORM. Some identities include

$$\delta(x - a) = 0 \quad (6)$$

for  $x \neq a$ ,

$$\int_{a-\epsilon}^{a+\epsilon} \delta(x - a) dx = 1, \quad (7)$$

where  $\epsilon$  is any POSITIVE number, and

$$\int_{-\infty}^{\infty} f(x) \delta(x - a) dx = f(a) \quad (8)$$

$$\int_{-\infty}^{\infty} f(x) \delta'(x - a) dx = -f'(a) \quad (9)$$

$$x \int f(x) \delta(x - x_0) dx = x_0 \int f(x) \delta(x - x_0) dx \quad (10)$$

$$\delta' * f = \int_{-\infty}^{\infty} \delta'(a - x) f(x) dx = f'(x) \quad (11)$$

$$\int_{-\infty}^{\infty} |\delta'(x)| dx = \infty \quad (12)$$

$$x^2 \delta'(x) = 0 \quad (13)$$

$$\delta'(-x) = -\delta'(x) \quad (14)$$

$$x \delta'(x) = -\delta(x). \quad (15)$$

(15) can be established using INTEGRATION BY PARTS as follows:

$$\begin{aligned} \int f(x) x \delta'(x) dx &= - \int \delta(x) \frac{d}{dx} [x f(x)] dx \\ &= - \int \delta[f(x) + x f'(x)] dx \\ &= - \int f(x) \delta(x) dx. \end{aligned} \quad (16)$$

Additional identities are

$$\delta(ax) = \frac{1}{a} \delta(x) \quad (17)$$

$$\delta(x^2 - a^2) = \frac{1}{2a} [\delta(x + a) + \delta(x - a)] \quad (18)$$

$$\delta[g(x)] = \sum_i \frac{\delta(x - x_i)}{|g'(x_i)|}, \quad (19)$$

where the  $x_i$ s are the ROOTS of  $g$ . For example, examine

$$\delta(x^2 + x - 2) = \delta[(x - 1)(x + 2)]. \quad (20)$$

Then  $g'(x) = 2x + 1$ , so  $g'(x_1) = g'(1) = 3$  and  $g'(x_2) = g'(-2) = -3$ , and we have

$$\delta(x^2 + x - 2) = \frac{1}{3} \delta(x - 1) + \frac{1}{3} \delta(x + 2). \quad (21)$$

A FOURIER SERIES expansion of  $\delta(x - a)$  gives

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} \delta(x - a) \cos(nx) dx = \frac{1}{\pi} \cos(na) \quad (22)$$

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} \delta(x - a) \sin(nx) dx = \frac{1}{\pi} \sin(na), \quad (23)$$

so

$$\begin{aligned} \delta(x - a) &= \frac{1}{2\pi} + \frac{1}{\pi} \sum_{n=1}^{\infty} [\cos(na) \cos(nx) + \sin(na) \sin(nx)] \\ &= \frac{1}{2\pi} + \frac{1}{\pi} \sum_{n=1}^{\infty} \cos[n(x - a)]. \end{aligned} \quad (24)$$

The FOURIER TRANSFORM of the delta function is

$$\mathcal{F}[\delta(x - x_0)] = \int_{-\infty}^{\infty} e^{-2\pi i k x} \delta(x - x_0) dx = e^{-2\pi i k x_0}. \quad (25)$$

Delta functions can also be defined in 2-D, so that in 2-D CARTESIAN COORDINATES

$$\delta^2(x - x_0, y - y_0) = \delta(x - x_0)\delta(y - y_0), \quad (26)$$

and in 3-D, so that in 3-D CARTESIAN COORDINATES

$$\delta^3(x - x_0, y - y_0, z - z_0) = \delta(x - x_0)\delta(y - y_0)\delta(z - z_0), \quad (27)$$

in CYLINDRICAL COORDINATES

$$\delta^3(r, \theta, z) = \frac{\delta(r)\delta(z)}{\pi r}, \quad (28)$$

and in SPHERICAL COORDINATES,

$$\delta^3(r, \theta, \phi) = \frac{\delta(r)}{2\pi r^2}. \quad (29)$$

A series expansion in CYLINDRICAL COORDINATES gives

$$\begin{aligned} \delta^3(\mathbf{r}_1 - \mathbf{r}_2) &= \frac{1}{r_1} \delta(r_1 - r_2) \delta(\phi_1 - \phi_2) \delta(z_1 - z_2) \\ &= \frac{1}{r_1} \delta(r_1 - r_2) \frac{1}{2\pi} \sum_{m=-\infty}^{\infty} e^{im(\phi_1 - \phi_2)} \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ik(z_1 - z_2)} dk. \end{aligned} \quad (30)$$

The delta function also obeys the so-called SIFTING PROPERTY

$$\int f(\mathbf{y}) \delta(\mathbf{x} - \mathbf{y}) d\mathbf{y} = f(\mathbf{x}). \quad (31)$$

#### Delta Sequence

A SEQUENCE of strongly peaked functions for which

$$\lim_{n \rightarrow \infty} \int_{-\infty}^{\infty} \delta_n(x) f(x) dx = f(n) \quad (1)$$

so that in the limit as  $n \rightarrow \infty$ , the sequences become DELTA FUNCTIONS. Examples include

$$\delta_n(x) = \begin{cases} 0 & x < -\frac{1}{2n} \\ n & -\frac{1}{2n} < x < \frac{1}{2n} \\ 0 & x > \frac{1}{2n} \end{cases} \quad (2)$$

$$= \frac{n}{\sqrt{\pi}} e^{-n^2 x^2} \quad (3)$$

$$= \frac{n}{\pi} \text{sinc}(ax) \equiv \frac{\sin(nx)}{\pi x} \quad (4)$$

$$= \frac{1}{\pi x} \frac{e^{inx} - e^{-inx}}{2i} \quad (5)$$

$$= \frac{1}{2\pi i x} [e^{ixt}]_{-n}^n \quad (6)$$

$$= \frac{1}{2\pi} \int_{-n}^n e^{ixt} dt \quad (7)$$

$$= \frac{1}{2\pi} \frac{\sin[(n + \frac{1}{2})x]}{\sin(\frac{1}{2}x)}, \quad (8)$$

where (8) is known as the DIRICHLET KERNEL.

#### Delta Variation

see VARIATION

#### Deltahedron

A semiregular POLYHEDRON whose faces are all EQUILATERAL TRIANGLES. There are an infinite number of deltahedra, but only eight convex ones (Freudenthal and van der Waerden 1947). They have 4, 6, 8, 10, 12, 14, 16, and 20 faces. These are summarized in the table below, and illustrated in the following figures.

$n$	Name
4	tetrahedron
6	triangular dipyramid
8	octahedron
10	pentagonal dipyramid
12	snub disphenoid
14	triaugmented triangular prism
16	gyroelongated square dipyramid
20	icosahedron

The STELLA OCTANGULA is a concave deltahedron with 24 sides:

Another with 60 faces is a “caved in” DODECAHEDRON which is ICOSAHDRON STELLATION  $I_{20}$ .

Cundy (1952) identifies 17 concave deltahedra with two kinds of VERTICES.

see also GYROELONGATED SQUARE DIPYRAMID, ICOSAHDREDON, OCTAHEDRON, PENTAGONAL DIPYRAMID, SNUB DISPHENOID TETRAHEDRON, TRIANGULAR DIPYRAMID, TRIAUGMENTED TRIANGULAR PRISM

#### Deltoid

A 3-cusped HYPOCYCLOID, also called a TRICUSPOID, which has  $n \equiv a/b = 3$  or  $3/2$ , where  $a$  is the RADIUS of the large fixed CIRCLE and  $b$  is the RADIUS of the small rolling CIRCLE. The deltoid was first considered by Euler in 1745 in connection with an optical problem. It was also investigated by Steiner in 1856 and is sometimes called STEINER’S HYPOCYCLOID (MacTutor Archive). The equation of the deltoid is obtained

by setting  $n = 3$  in the equation of the HYPOCYCLOID, yielding the parametric equations

$$x = \left[ \frac{2}{3} \cos \phi - \frac{1}{3} \cos(2\phi) \right] a = 2b \cos \phi + b \cos(2\phi) \quad (1)$$

$$y = \left[ \frac{2}{3} \sin \phi + \frac{1}{3} \sin(2\phi) \right] a = 2b \sin \phi - b \sin(2\phi). \quad (2)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = 4 \int_0^t \left| \sin\left(\frac{3}{2}t'\right) \right| dt' = \frac{16}{3} \sin^2\left(\frac{3}{4}t\right) \quad (3)$$

$$\kappa(t) = -\frac{1}{8} \csc\left(\frac{3}{2}t\right) \quad (4)$$

$$\phi(t) = -\frac{1}{2}t. \quad (5)$$

As usual, care must be taken in the evaluation of  $s(t)$  for  $t > 2\pi/3$ . Since the form given above comes from an integral involving the ABSOLUTE VALUE of a function, it must be monotonic increasing. Each branch can be treated correctly by defining

$$n = \left\lfloor \frac{3t}{2\pi} \right\rfloor + 1, \quad (6)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, giving the formula

$$s(t) = (-1)^{1+[n \pmod{2}]} \frac{16}{3} \sin^2\left(\frac{3}{4}t\right) + \frac{32}{3} \left\lfloor \frac{1}{2}n \right\rfloor. \quad (7)$$

The total ARC LENGTH is computed from the general HYPOCYCLOID equation

$$s_n = \frac{8a(n-1)}{n}. \quad (8)$$

With  $n = 3$ , this gives

$$s_3 = \frac{16}{3}a. \quad (9)$$

The AREA is given by

$$A_n = \frac{(n-1)(n-2)}{n^2} \pi a^2 \quad (10)$$

with  $n = 3$ ,

$$A_3 = \frac{2}{9} \pi a^2. \quad (11)$$

The length of the tangent to the tricuspid, measured between the two points  $P, Q$  in which it cuts the curve again, is constant and equal to  $4a$ . If you draw TANGENTS at  $P$  and  $Q$ , they are at RIGHT ANGLES.

## Deltoid Caustic

The caustic of the DELTOID when the rays are PARALLEL in any direction is an ASTROID.

## Deltoid Evolute

A HYPOCYCLOID EVOLUTE for  $n = 3$  is another DELTOID scaled by a factor  $n/(n-2) = 3/1 = 3$  and rotated  $1/(2 \cdot 3) = 1/6$  of a turn.

## Deltoid Involute

A HYPOCYCLOID INVOLUTE for  $n = 3$  is another DELTOID scaled by a factor  $(n-2)/n = 1/3$  and rotated  $1/(2 \cdot 3) = 1/6$  of a turn.

## Deltoid Pedal Curve

The PEDAL CURVE for a DELTOID with the PEDAL POINT at the CUSP is a FOLIUM. For the PEDAL POINT at the CUSP (NEGATIVE  $x$ -intercept), it is a BIFOLIUM. At the center, or anywhere on the inscribed EQUILATERAL TRIANGLE, it is a TRIFOLIUM.

## Deltoid Radial Curve

The TRIFOLIUM

$$x = x_0 + 4a \cos \phi - 4a \cos(2\phi)$$

$$y = y_0 + 4a \sin \phi + 4a \sin(2\phi).$$

## Deltoidal Hexecontahedron

The DUAL POLYHEDRON of the RHOMBICOSIDODECAHEDRON.

## Deltoidal Icositetrahedron

The DUAL POLYHEDRON of the SMALL RHOMBICUB-OCTAHEDRON. It is also called the TRAPEZOIDAL ICOSITETRAHEDRON.

### Demlo Number

The initially PALINDROMIC NUMBERS 1, 121, 12321, 1234321, 123454321, ... (Sloane's A002477). For the first through ninth terms, the sequence is given by the GENERATING FUNCTION

$$\frac{10x + 1}{(x-1)(10x-1)(100x-1)} \\ = 1 + 121x + 12321x^2 + 1234321x^3 + \dots$$

(Plouffe 1992, Sloane and Plouffe 1995). The definition of this sequence is slightly ambiguous from the tenth term on.

see also CONSECUTIVE NUMBER SEQUENCES, PALINDROMIC NUMBER

### Dendrite Fractal

A JULIA SET with  $c = i$ .

### Denjoy Integral

A type of INTEGRAL which is an extension of both the RIEMANN INTEGRAL and the LEBESGUE INTEGRAL. The original Denjoy integral is now called a Denjoy integral "in the restricted sense," and a more general type is now called a Denjoy integral "in the wider sense." The independently discovered PERON INTEGRAL turns out to be equivalent to the Denjoy integral "in the restricted sense."

see also INTEGRAL, LEBESGUE INTEGRAL, PERON INTEGRAL, RIEMANN INTEGRAL

### Denominator

The number  $q$  in a FRACTION  $p/q$ .

see also FRACTION, NUMERATOR, RATIO, RATIONAL NUMBER

### Dense

A set  $A$  in a FIRST-COUNTABLE SPACE is dense in  $B$  if  $B = A \cup L$ , where  $L$  is the limit of sequences of elements of  $A$ . For example, the rational numbers are dense in the reals. In general, a SUBSET  $A$  of  $X$  is dense if its CLOSURE  $\text{cl}(A) = X$ .

see also CLOSURE, DENSITY, DERIVED SET, PERFECT SET

### Density

see DENSITY (POLYGON), DENSITY (SEQUENCE), NATURAL DENSITY

### Density (Polygon)

The number  $q$  in a STAR POLYGON  $\{\frac{p}{q}\}$ .

see also STAR POLYGON

### Density (Sequence)

Let a SEQUENCE  $\{a_i\}_{i=1}^{\infty}$  be strictly increasing and composed of NONNEGATIVE INTEGERS. Call  $A(x)$  the number of terms not exceeding  $x$ . Then the density is given by  $\lim_{x \rightarrow \infty} A(x)/x$  if the LIMIT exists.

### Denumerable Set

A SET is denumerable if a prescription can be given for identifying its members one at a time. Such a set is said to have CARDINAL NUMBER  $\aleph_0$ . Examples of denumerable sets include ALGEBRAIC NUMBERS, INTEGERS, and RATIONAL NUMBERS. Once one denumerable set  $S$  is given, any other set which can be put into a ONE-TO-ONE correspondence with  $S$  is also denumerable. Examples of nondenumerable sets include the REAL, COMPLEX, IRRATIONAL, and TRANSCENDENTAL NUMBERS.

### Denumerably Infinite

see DENUMERABLE SET

**Depth (Graph)**

The depth  $E(G)$  of a GRAPH  $G$  is the minimum number of PLANAR GRAPHS  $P_i$  needed such that the union  $\cup_i P_i = G$ .

see also PLANAR GRAPH

**Depth (Size)**

The depth of a box is the horizontal DISTANCE from front to back (usually not necessarily defined to be smaller than the WIDTH, the horizontal DISTANCE from side to side).

see also HEIGHT, WIDTH (SIZE)

**Depth (Statistics)**

The smallest RANK (either up or down) of a set of data.

**References**

Tukey, J. W. *Explanatory Data Analysis*. Reading, MA: Addison-Wesley, p. 30, 1977.

**Depth (Tree)**

The depth of a RESOLVING TREE is the number of levels of links, not including the top. The depth of the link is the minimal depth for any RESOLVING TREE of that link. The only links of length 0 are the trivial links. A KNOT of length 1 is always a trivial KNOT and links of depth one are always HOPF LINKS, possibly with a few additional trivial components (Bleiler and Scharlemann). The LINKS of depth two have also been classified (Thompson and Scharlemann).

**References**

Adams, C. C. *The Knot Book: An Elementary Introduction to the Mathematical Theory of Knots*. New York: W. H. Freeman, p. 169, 1994.

**Derangement**

A PERMUTATION of  $n$  ordered objects in which none of the objects appears in its natural place. The function giving this quantity is the SUBFACTORIAL  $!n$ , defined by

$$!n \equiv n! \sum_{k=0}^n \frac{(-1)^k}{k!} \quad (1)$$

or

$$!n \equiv \left[ \frac{n!}{e} \right], \quad (2)$$

where  $k!$  is the usual FACTORIAL and  $[x]$  is the NINT function. These are also called RENCONTRES NUMBERS (named after rencontres solitaire), or COMPLETE PERMUTATIONS, or derangements. The number of derangements  $!n = d(n)$  of length  $n$  satisfy the RECURRENCE RELATIONS

$$d(n) = (n-1)[d(n-1) + d(n-2)] \quad (3)$$

and

$$d(n) = nd(n-1) + (-1)^n, \quad (4)$$

with  $d(1) = 0$  and  $d(2) = 1$ . The first few are 0, 1, 2, 9, 44, 265, 1854, ... (Sloane's A000166). This sequence cannot be expressed as a fixed number of hypergeometric terms (Petkovšek *et al.* 1996, pp. 157–160).

**Derivative**

The derivative of a FUNCTION represents an infinitesimal change in the function with respect to whatever parameters it may have. The "simple" derivative of a function  $f$  with respect to  $x$  is denoted either  $f'(x)$  or  $\frac{df}{dx}$  (and often written in-line as  $df/dx$ ). When derivatives are taken with respect to time, they are often denoted using Newton's FLUXION notation,  $\frac{dx}{dt} = \dot{x}$ . The derivative of a function  $f(x)$  with respect to the variable  $x$  is defined as

$$f'(x) \equiv \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}. \quad (1)$$

Note that in order for the limit to exist, both  $\lim_{h \rightarrow 0+}$  and  $\lim_{h \rightarrow 0-}$  must exist and be equal, so the FUNCTION must be continuous. However, continuity is a NECESSARY but *not* SUFFICIENT condition for differentiability. Since some DISCONTINUOUS functions can be integrated, in a sense there are "more" functions which can be integrated than differentiated. In a letter to Stieltjes, Hermite wrote, "I recoil with dismay and horror at this lamentable plague of functions which do not have derivatives."

A 3-D generalization of the derivative to an arbitrary direction is known as the DIRECTIONAL DERIVATIVE.

In general, derivatives are mathematical objects which exist between smooth functions on manifolds. In this formalism, derivatives are usually assembled into "TANGENT MAPS."

Simple derivatives of some simple functions follow.

$$\frac{d}{dx} x^n = nx^{n-1} \quad (2)$$

$$\frac{d}{dx} \ln |x| = \frac{1}{x} \quad (3)$$

$$\frac{d}{dx} \sin x = \cos x \quad (4)$$

$$\frac{d}{dx} \cos x = -\sin x \quad (5)$$

$$\begin{aligned} \frac{d}{dx} \tan x &= \frac{d}{dx} \left( \frac{\sin x}{\cos x} \right) = \frac{\cos x \cos x - \sin x(-\sin x)}{\cos^2 x} \\ &= \frac{1}{\cos^2 x} = \sec^2 x \end{aligned} \quad (6)$$

$$\begin{aligned} \frac{d}{dx} \csc x &= \frac{d}{dx} (\sin x)^{-1} = -(\sin x)^{-2} \cos x = -\frac{\cos x}{\sin^2 x} \\ &= -\csc x \cot x \end{aligned} \quad (7)$$

$$\begin{aligned} \frac{d}{dx} \sec x &= \frac{d}{dx} (\cos x)^{-1} = -(\cos x)^{-2} (-\sin x) = \frac{\sin x}{\cos^2 x} \\ &= \sec x \tan x \end{aligned} \quad (8)$$

$$\begin{aligned} \frac{d}{dx} \cot x &= \frac{d}{dx} \left( \frac{\cos x}{\sin x} \right) = \frac{\sin x(-\sin x) - \cos x \cos x}{\cos^2 x} \\ &= -\frac{1}{\cos^2 x} = -\csc^2 x \end{aligned} \quad (9)$$

$$\frac{d}{dx} e^x = e^x \quad (10)$$

$$\begin{aligned} \frac{d}{dx} a^x &= \frac{d}{dx} e^{x \ln a} = \frac{d}{dx} e^{x \ln a} \\ &= (\ln a) e^{x \ln a} = (\ln a) a^x \end{aligned} \quad (11)$$

$$\frac{d}{dx} \sin^{-1} x = \frac{1}{\sqrt{1-x^2}} \quad (12)$$

$$\frac{d}{dx} \cos^{-1} x = -\frac{1}{\sqrt{1-x^2}} \quad (13)$$

$$\frac{d}{dx} \tan^{-1} x = \frac{1}{1+x^2} \quad (14)$$

$$\frac{d}{dx} \cot^{-1} x = -\frac{1}{1+x^2} \quad (15)$$

$$\frac{d}{dx} \sec^{-1} x = \frac{1}{x\sqrt{x^2-1}} \quad (16)$$

$$\frac{d}{dx} \csc^{-1} x = -\frac{1}{x\sqrt{x^2-1}} \quad (17)$$

$$\frac{d}{dx} \sinh x = \cosh x \quad (18)$$

$$\frac{d}{dx} \cosh x = \sinh x \quad (19)$$

$$\frac{d}{dx} \tanh x = \operatorname{sech}^2 x \quad (20)$$

$$\frac{d}{dx} \coth x = -\operatorname{csch}^2 x \quad (21)$$

$$\frac{d}{dx} \operatorname{sech} x = -\operatorname{sech} x \tanh x \quad (22)$$

$$\frac{d}{dx} \operatorname{csch} x = -\operatorname{csch} x \coth x \quad (23)$$

$$\frac{d}{dx} \operatorname{sn} x = \operatorname{cn} x \operatorname{dn} x \quad (24)$$

$$\frac{d}{dx} \operatorname{cn} x = -\operatorname{sn} x \operatorname{dn} x \quad (25)$$

$$\frac{d}{dx} \operatorname{dn} x = -k^2 \operatorname{sn} x \operatorname{cn} x. \quad (26)$$

Derivatives of sums are equal to the sum of derivatives so that

$$[f(x) + \dots + h(x)]' = f'(x) + \dots + h'(x). \quad (27)$$

In addition, if  $c$  is a constant,

$$\frac{d}{dx} [cf(x)] = cf'(x). \quad (28)$$

Furthermore,

$$\frac{d}{dx} [f(x)g(x)] = f(x)g'(x) + f'(x)g(x), \quad (29)$$

where  $f'$  denotes the DERIVATIVE of  $f$  with respect to  $x$ . This derivative rule can be applied iteratively to yield derivate rules for products of three or more functions, for example,

$$\begin{aligned} [fgh]' &= (fg)h' + (fg)'h = fgh' + (f'g + fg')h \\ &= f'gh + fg'h + fgh'. \end{aligned} \quad (30)$$

Other rules involving derivatives include the CHAIN RULE, POWER RULE, PRODUCT RULE, and QUOTIENT RULE. Miscellaneous other derivative identities include

$$\frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} \quad (31)$$

$$\frac{dy}{dx} = \frac{1}{\frac{dx}{dy}}. \quad (32)$$

If  $F(x, y) = C$ , where  $C$  is a constant, then

$$dF = \frac{\partial F}{\partial y} dy + \frac{\partial F}{\partial x} dx = 0, \quad (33)$$

so

$$\frac{dy}{dx} = -\frac{\frac{\partial F}{\partial x}}{\frac{\partial F}{\partial y}}. \quad (34)$$

A vector derivative of a vector function

$$\mathbf{X}(t) \equiv \begin{bmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_k(t) \end{bmatrix} \quad (35)$$

can be defined by

$$\frac{d\mathbf{X}}{dt} = \begin{bmatrix} \frac{dx_1}{dt} \\ \frac{dx_2}{dt} \\ \vdots \\ \frac{dx_k}{dt} \end{bmatrix} \quad (36)$$

#### Dervish

A QUINTIC SURFACE having the maximum possible number of ORDINARY DOUBLE POINTS (31), which was constructed by W. Barth in 1994 (Endraß). The implicit equation of the surface is

$$\begin{aligned} &64(x-w)[x^4 - 4x^3w - 10x^2y^2 - 4x^2w^2 \\ &+ 16xw^3 - 20xy^2w + 5y^4 + 16w^4 - 20y^2w^2] \\ &- 5\sqrt{5 - \sqrt{5}}(2z - \sqrt{5 - \sqrt{5}}w) \\ &\times [4(x^2 + y^2 + z^2) + (1 + 3\sqrt{5})w^2]^2, \end{aligned}$$

where  $w$  is a parameter (Endraß). The surface can also be described by the equation

$$aF + q = 0, \quad (1)$$

where

$$F = h_1h_2h_3h_4h_5, \quad (2)$$

$$h_1 = x - z \quad (3)$$

$$h_2 = \cos\left(\frac{2\pi}{5}\right)x - \sin\left(\frac{2\pi}{5}\right)y - z \quad (4)$$

$$h_3 = \cos\left(\frac{4\pi}{5}\right)x - \sin\left(\frac{4\pi}{5}\right)y - z \quad (5)$$

$$h_4 = \cos\left(\frac{6\pi}{5}\right)x - \sin\left(\frac{6\pi}{5}\right)y - z \quad (6)$$

$$h_5 = \cos\left(\frac{8\pi}{5}\right)x - \sin\left(\frac{8\pi}{5}\right)y - z \quad (7)$$

$$q = (1 - cz)(x^2 + y^2 - 1 + rz^2)^2, \quad (8)$$

and

$$r = \frac{1}{4}(1 + \sqrt{5}) \quad (9)$$

$$a = -\frac{8}{5}\left(1 + \frac{1}{\sqrt{5}}\right)\sqrt{5 - \sqrt{5}} \quad (10)$$

$$c = \frac{1}{2}\sqrt{5 - \sqrt{5}} \quad (11)$$

(Nordstrand).

The dervish is invariant under the GROUP  $D_5$  and contains exactly 15 lines. Five of these are the intersection of the surface with a  $D_5$ -invariant cone containing 16 nodes, five are the intersection of the surface with a  $D_5$ -invariant plane containing 10 nodes, and the last five are the intersection of the surface with a second  $D_5$ -invariant plane containing no nodes (Endraß).

#### Desargues' Theorem

If the three straight LINES joining the corresponding VERTICES of two TRIANGLES  $ABC$  and  $A'B'C'$  all meet in a point (the PERSPECTIVE CENTER), then the three intersections of pairs of corresponding sides lie on a straight LINE (the PERSPECTIVE AXIS). Equivalently, if two TRIANGLES are PERSPECTIVE from a POINT, they are PERSPECTIVE from a LINE.

Desargues' theorem is essentially its own dual according to the DUALITY PRINCIPLE of PROJECTIVE GEOMETRY.

### Descartes Circle Theorem

A special case of APOLLONIUS' PROBLEM requiring the determination of a CIRCLE touching three mutually tangent CIRCLES (also called the KISSING CIRCLES PROBLEM). There are two solutions: a small circle surrounded by the three original CIRCLES, and a large circle surrounding the original three. Frederick Soddy gave the FORMULA for finding the RADIUS of the so-called inner and outer SODDY CIRCLES given the RADII of the other three. The relationship is

$$2(\kappa_1^2 + \kappa_2^2 + \kappa_3^2 + \kappa_4^2) = (\kappa_1 + \kappa_2 + \kappa_3 + \kappa_4)^2,$$

where  $\kappa_i$  are the CURVATURES of the CIRCLES. Here, the NEGATIVE solution corresponds to the outer SODDY CIRCLE and the POSITIVE solution to the inner SODDY CIRCLE. This formula was known to Descartes and Viète (Boyer and Merzbach 1991, p. 159), but Soddy extended it to SPHERES. In  $n$ -D space,  $n + 2$  mutually touching  $n$ -SPHERES can always be found, and the relationship of their CURVATURES is

$$n \left( \sum_{i=1}^{n+2} \kappa_i^2 \right) = \left( \sum_{i=1}^{n+2} \kappa_i \right)^2.$$

### Descartes' Sign Rule

A method of determining the maximum number of POSITIVE and NEGATIVE REAL ROOTS of a POLYNOMIAL.

For POSITIVE ROOTS, start with the SIGN of COEFFICIENT of the lowest (or highest) POWER. Count the number of SIGN changes  $n$  as you proceed from the lowest to the highest POWER (ignoring POWERS which do not appear). Then  $n$  is the *maximum* number of POSITIVE ROOTS. Furthermore, the number of allowable ROOTS is  $n, n - 2, n - 4, \dots$ . For example, consider the POLYNOMIAL

$$f(x) = x^7 + x^6 - x^4 - x^3 - x^2 + x - 1.$$

Since there are three SIGN changes, there are a maximum of three possible POSITIVE ROOTS.

For NEGATIVE ROOTS, starting with a POLYNOMIAL  $f(x)$ , write a new POLYNOMIAL  $g(x)$  with the SIGNS of all ODD POWERS reversed, while leaving the SIGNS of the EVEN POWERS unchanged. Then proceed as before to count the number of SIGN changes  $n$ . Then  $n$  is the *maximum* number of NEGATIVE ROOTS. For example, consider the POLYNOMIAL

$$f(x) = x^7 + x^6 - x^4 - x^3 - x^2 + x - 1,$$

and compute the new POLYNOMIAL

$$g(x) = -x^7 + x^6 - x^4 + x^3 - x^2 - x - 1.$$

There are four SIGN changes, so there are a maximum of four NEGATIVE ROOTS.

### Descartes Total Angular Defect

The total angular defect is the sum of the ANGULAR DEFECTS over all VERTICES of a POLYHEDRON, where the ANGULAR DEFECT  $\delta$  at a given VERTEX is the difference between the sum of face angles and  $2\pi$ . For any convex POLYHEDRON, the Descartes total angular defect is

$$\Delta = \sum_i \delta_i = 4\pi. \quad (1)$$

This is equivalent to the POLYHEDRAL FORMULA for a closed rectilinear surface, which satisfies

$$\Delta = 2\pi(V - E + F). \quad (2)$$

A POLYHEDRON with  $N_0$  equivalent VERTICES is called a PLATONIC SOLID and can be assigned a SCHLÄFLI SYMBOL  $\{p, q\}$ . It then satisfies

$$N_0 = \frac{4\pi}{\delta} \quad (3)$$

and

$$\delta = 2\pi - q \left( 1 - \frac{2}{p} \right) \pi, \quad (4)$$

so

$$N_0 = \frac{4p}{2p + 2q - pq}. \quad (5)$$

### Desmic Surface

Let  $\Delta_1$ ,  $\Delta_2$ , and  $\Delta_3$  be tetrahedra in projective 3-space  $\mathbb{P}^3$ . Then the tetrahedra are said to be desmically related if there exist constants  $\alpha$ ,  $\beta$ , and  $\gamma$  such that

$$\alpha\Delta_1 + \beta\Delta_2 + \gamma\Delta_3 = 0.$$

A desmic surface is then defined as a QUARTIC SURFACE which can be written as

$$a\Delta_1 + b\Delta_2 + c\Delta_3 = 0$$

for desmically related tetrahedra  $\Delta_1$ ,  $\Delta_2$ , and  $\Delta_3$ . Desmic surfaces have 12 ORDINARY DOUBLE POINTS, which are the vertices of three tetrahedra in 3-space (Hunt).

### Destructive Dilemma

A formal argument in LOGIC in which it is stated that

1.  $P \Rightarrow Q$  and  $R \Rightarrow S$  (where  $\Rightarrow$  means "IMPLIES"), and
2. Either not- $Q$  or not- $S$  is true, from which two statements it follows that either not- $P$  or not- $R$  is true.

see also CONSTRUCTIVE DILEMMA, DILEMMA

### Determinant

Determinants are mathematical objects which are very useful in the analysis and solution of systems of linear equations. As shown in CRAMER'S RULE, a nonhomogeneous system of linear equations has a nontrivial solution IFF the determinant of the system's MATRIX is NONZERO (so that the MATRIX is nonsingular). A  $2 \times 2$  determinant is defined to be

$$\det \begin{bmatrix} a & b \\ c & d \end{bmatrix} \equiv \begin{vmatrix} a & b \\ c & d \end{vmatrix} \equiv ad - bc. \quad (1)$$

A  $k \times k$  determinant can be expanded by MINORS to obtain

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1k} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2k} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & a_{k3} & \cdots & a_{kk} \end{vmatrix} \\ = a_{11} \begin{vmatrix} a_{22} & a_{23} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k2} & a_{k3} & \cdots & a_{kk} \end{vmatrix} - a_{12} \begin{vmatrix} a_{21} & a_{23} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k3} & \cdots & a_{kk} \end{vmatrix} \\ + \dots \pm a_{1k} \begin{vmatrix} a_{21} & a_{22} & \cdots & a_{2(k-1)} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{k(k-1)} \end{vmatrix}. \quad (2)$$

A general determinant for a MATRIX  $A$  has a value

$$|A| = \sum_i a_{ij} a^{ij}, \quad (3)$$

with no implied summation over  $i$  and where  $a^{ij}$  is the COFACTOR of  $a_{ij}$  defined by

$$a^{ij} \equiv (-1)^{i+j} C_{ij}. \quad (4)$$

Here,  $C$  is the  $(n-1) \times (n-1)$  MATRIX formed by eliminating row  $i$  and column  $j$  from  $A$ , i.e., by DETERMINANT EXPANSION BY MINORS.

Given an  $n \times n$  determinant, the additive inverse is

$$|-A| = (-1)^n |A|. \quad (5)$$

Determinants are also DISTRIBUTIVE, so

$$|AB| = |A| |B|. \quad (6)$$

This means that the determinant of a MATRIX INVERSE can be found as follows:

$$|| = |AA^{-1}| = |A| |A^{-1}| = 1, \quad (7)$$

where  $I$  is the IDENTITY MATRIX, so

$$|A| = \frac{1}{|A^{-1}|}. \quad (8)$$

Determinants are MULTILINEAR in rows and columns, since

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} = \begin{vmatrix} a_1 & 0 & 0 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} \\ + \begin{vmatrix} 0 & a_2 & 0 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} + \begin{vmatrix} 0 & 0 & a_3 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} \quad (9)$$

and

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} = \begin{vmatrix} a_1 & a_2 & a_3 \\ 0 & a_5 & a_6 \\ 0 & a_8 & a_9 \end{vmatrix} \\ + \begin{vmatrix} 0 & a_2 & a_3 \\ a_4 & a_5 & a_6 \\ 0 & a_8 & a_9 \end{vmatrix} + \begin{vmatrix} 0 & a_2 & a_3 \\ 0 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix}. \quad (10)$$

The determinant of the SIMILARITY TRANSFORMATION of a matrix is equal to the determinant of the original MATRIX

$$|BAB^{-1}| = |B| |A| |B^{-1}| = |B| |A| \frac{1}{|B^{-1}|} = |A|. \quad (11)$$

The determinant of a similarity transformation minus a multiple of the unit MATRIX is given by

$$|B^{-1}AB - \lambda I| = |B^{-1}AB - B^{-1}\lambda B| = |B^{-1}(A - \lambda I)B| \\ = |B^{-1}| |A - \lambda I| |B| = |A - \lambda I|. \quad (12)$$

The determinant of a MATRIX TRANSPOSE equals the determinant of the original MATRIX,

$$|A| = |A^T|, \quad (13)$$

and the determinant of a COMPLEX CONJUGATE is equal to the COMPLEX CONJUGATE of the determinant

$$|A^*| = |A|^*. \quad (14)$$

Let  $\epsilon$  be a small number. Then

$$|I + \epsilon A| = 1 + \epsilon \text{Tr}(A) + \mathcal{O}(\epsilon^2), \quad (15)$$

where  $\text{Tr}(A)$  is the trace of  $A$ . The determinant takes on a particularly simple form for a TRIANGULAR MATRIX

$$\begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ 0 & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a_{kk} \end{vmatrix} = \prod_{n=1}^k a_{nn}. \quad (16)$$

Important properties of the determinant include the following.

1. Switching two rows or columns changes the sign.
2. Scalars can be factored out from rows and columns.
3. Multiples of rows and columns can be added together without changing the determinant's value.
4. Scalar multiplication of a row by a constant  $c$  multiplies the determinant by  $c$ .
5. A determinant with a row or column of zeros has value 0.
6. Any determinant with two rows or columns equal has value 0.

Property 1 can be established by induction. For a  $2 \times 2$  MATRIX, the determinant is

$$\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = a_1 b_2 - b_1 a_2 = -(b_1 a_2 - a_1 b_2) \\ = - \begin{vmatrix} b_1 & a_1 \\ b_2 & a_2 \end{vmatrix} \quad (17)$$

For a  $3 \times 3$  MATRIX, the determinant is

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} \\ = a_1 \begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} - b_1 \begin{vmatrix} a_2 & c_2 \\ a_3 & c_3 \end{vmatrix} + c_1 \begin{vmatrix} a_2 & b_2 \\ a_3 & b_3 \end{vmatrix} \\ = - \left( a_1 \begin{vmatrix} c_2 & b_2 \\ c_3 & b_3 \end{vmatrix} + b_1 \begin{vmatrix} c_2 & a_2 \\ c_3 & a_3 \end{vmatrix} - c_1 \begin{vmatrix} a_2 & b_2 \\ a_3 & b_3 \end{vmatrix} \right) \\ = - \begin{vmatrix} a_1 & c_1 & b_1 \\ a_2 & c_2 & b_2 \\ a_3 & c_3 & b_3 \end{vmatrix} \\ = - \left( -a_1 \begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} + b_1 \begin{vmatrix} a_2 & c_2 \\ a_3 & c_3 \end{vmatrix} + c_1 \begin{vmatrix} b_2 & a_2 \\ b_3 & a_3 \end{vmatrix} \right) \\ = - \begin{vmatrix} b_1 & a_1 & c_1 \\ b_2 & a_2 & c_2 \\ b_3 & a_3 & c_3 \end{vmatrix} \\ = - \left( -a_1 \begin{vmatrix} c_2 & b_2 \\ c_3 & b_3 \end{vmatrix} - b_1 \begin{vmatrix} a_2 & c_2 \\ a_3 & c_3 \end{vmatrix} + c_1 \begin{vmatrix} b_2 & a_2 \\ b_3 & a_3 \end{vmatrix} \right) \\ = - \begin{vmatrix} c_1 & b_1 & a_1 \\ c_2 & b_2 & a_2 \\ c_3 & b_3 & a_3 \end{vmatrix}. \quad (18)$$

Property 2 follows likewise. For  $2 \times 2$  and  $3 \times 3$  matrices,

$$\begin{vmatrix} ka_1 & b_1 \\ ka_2 & b_2 \end{vmatrix} = k(a_1 b_2) - k(b_1 a_2) = k \begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} \quad (19)$$

and

$$\begin{vmatrix} ka_1 & b_1 & c_1 \\ ka_2 & b_2 & c_2 \\ ka_3 & b_3 & c_3 \end{vmatrix} = ka_1 \begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} - b_1 \begin{vmatrix} ka_2 & c_2 \\ ka_3 & c_3 \end{vmatrix} \\ + c_1 \begin{vmatrix} ka_2 & b_2 \\ ka_3 & b_3 \end{vmatrix} = k \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}. \quad (20)$$

Property 3 follows from the identity

$$\begin{vmatrix} a_1 + kb_1 & b_1 & c_1 \\ a_2 + kb_2 & b_2 & c_2 \\ a_3 + kb_3 & b_3 & c_3 \end{vmatrix} = (a_1 + kb_1) \begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} \\ - b_1 \begin{vmatrix} a_2 + kb_2 & c_2 \\ a_3 + kb_3 & c_3 \end{vmatrix} + c_1 \begin{vmatrix} a_2 + kb_2 & b_2 \\ a_3 + kb_3 & b_3 \end{vmatrix}. \quad (21)$$

If  $a_{ij}$  is an  $n \times n$  MATRIX with  $a_{ij}$  REAL NUMBERS, then  $\det[a_{ij}]$  has the interpretation as the oriented  $n$ -dimensional CONTENT of the PARALLELEPIPED spanned

by the column vectors  $[a_{i,1}], \dots, [a_{i,n}]$  in  $\mathbb{R}^n$ . Here, “oriented” means that, up to a change of  $+$  or  $-$  SIGN, the number is the  $n$ -dimensional CONTENT, but the SIGN depends on the “orientation” of the column vectors involved. If they agree with the standard orientation, there is a  $+$  SIGN; if not, there is a  $-$  SIGN. The PARALLELEPIPED spanned by the  $n$ -D vectors  $\mathbf{v}_1$  through  $\mathbf{v}_i$  is the collection of points

$$t_1 \mathbf{v}_1 + \dots + t_i \mathbf{v}_i, \quad (22)$$

where  $t_j$  is a REAL NUMBER in the CLOSED INTERVAL  $[0,1]$ .

There are an infinite number of  $3 \times 3$  determinants with no 0 or  $\pm 1$  entries having unity determinant. One parametric family is

$$\begin{vmatrix} -8n^2 - 8n & 2n + 1 & 4n \\ -4n^2 - 4n & n + 1 & 2n + 1 \\ -4n^2 - 4n - 1 & n & 2n - 1 \end{vmatrix}. \quad (23)$$

Specific examples having small entries include

$$\begin{vmatrix} 2 & 3 & 2 \\ 4 & 2 & 3 \\ 9 & 6 & 7 \end{vmatrix}, \begin{vmatrix} 2 & 3 & 5 \\ 3 & 2 & 3 \\ 9 & 5 & 7 \end{vmatrix}, \begin{vmatrix} 2 & 3 & 6 \\ 3 & 2 & 3 \\ 17 & 11 & 16 \end{vmatrix}, \dots \quad (24)$$

(Guy 1989, 1994).

## Determinant (Binary Quadratic Form)

The determinant of a BINARY QUADRATIC FORM

$$Au^2 + 2Buv + Cv^2$$

is

$$D \equiv B^2 - AC.$$

It is equal to 1/4 of the corresponding DISCRIMINANT.

**Determinant Expansion by Minors**

Also known as LAPLACIAN DETERMINANT EXPANSION BY MINORS. Let  $|M|$  denote the DETERMINANT of a MATRIX  $M$ , then

$$|M| = \sum_{i=1}^k (-1)^{i+j} a_i M_{ij},$$

where  $M_{ij}$  is called a MINOR,

$$|M| = \sum_{i=1}^k a_i C_{ij},$$

where  $C_{ij}$  is called a COFACTOR.

see also COFACTOR, DETERMINANT

**Determinant (Knot)**

see KNOT DETERMINANT

**Determinant Theorem**

Given a MATRIX  $m$ , the following are equivalent:

1.  $|m| \neq 0$ .
2. The columns of  $m$  are linearly independent.
3. The rows of  $m$  are linearly independent.
4.  $\text{Range}(m) = \mathbb{R}^n$ .
5.  $\text{Null}(m) = \{0\}$ .
6.  $m$  has a MATRIX INVERSE.

**Developable Surface**

A surface on which the GAUSSIAN CURVATURE  $K$  is everywhere 0.

see also BINORMAL DEVELOPABLE, NORMAL DEVELOPABLE, SYNCLASTIC, TANGENT DEVELOPABLE

**Deviation**

The DIFFERENCE of a quantity from some fixed value, usually the “correct” or “expected” one.

see ABSOLUTE DEVIATION, AVERAGE ABSOLUTE DEVIATION, DIFFERENCE, DISPERSION (STATISTICS), MEAN DEVIATION, SIGNED DEVIATION, STANDARD DEVIATION

**Devil's Curve**

The devil's curve was studied by G. Cramer in 1750 and Lacroix in 1810 (MacTutor Archive). It appeared in *Nouvelles Annales* in 1858. The Cartesian equation is

$$y^4 - a^2 y^2 = x^4 - b^2 x^2, \quad (1)$$

equivalent to

$$y^2(y^2 - a^2) = x^2(x^2 - b^2), \quad (2)$$

the polar equation is

$$r^2(\sin^2 \theta - \cos^2 \theta) = a^2 \sin^2 \theta - b^2 \cos^2 \theta, \quad (3)$$

and the parametric equations are

$$x = \cos t \sqrt{\frac{a^2 \sin^2 t - b^2 \cos^2 t}{\sin^2 t - \cos^2 t}} \quad (4)$$

$$y = \sin t \sqrt{\frac{a^2 \sin^2 t - b^2 \cos^2 t}{\sin^2 t - \cos^2 t}}. \quad (5)$$

A special case of the Devil's curve is the so-called ELECTRIC MOTOR CURVE:

$$y^2(y^2 - 96) = x^2(x^2 - 100) \quad (6)$$

(Cundy and Rollett 1989).

see also ELECTRIC MOTOR CURVE

**Devil's Staircase**

A plot of the WINDING NUMBER  $W$  resulting from MODE LOCKING as a function of  $\Omega$  for the CIRCLE MAP with  $K = 1$ . At each value of  $\Omega$ , the WINDING NUMBER is some RATIONAL NUMBER. The result is a monotonic increasing "staircase" for which the simplest RATIONAL NUMBERS have the largest steps. For  $K = 1$ , the MEASURE of quasiperiodic states ( $\Omega$  IRRATIONAL) on the  $\Omega$ -axis has become zero, and the measure of MODE-LOCKED state has become 1. The DIMENSION of the Devil's staircase  $\approx 0.8700 \pm 3.7 \times 10^{-4}$ .

**Diagonal Matrix**

A diagonal matrix is a MATRIX  $A$  of the form

$$a_{ij} = c_i \delta_{ij}, \quad (1)$$

where  $\delta$  is the KRONECKER DELTA,  $c_i$  are constants, and there is no summation over indices. The general diagonal matrix is therefore SQUARE and of the form

$$\begin{bmatrix} c_1 & 0 & \cdots & 0 \\ 0 & c_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & c_n \end{bmatrix}. \quad (2)$$

Given a MATRIX equation of the form

$$\begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_n \end{bmatrix} = \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_n \end{bmatrix} \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{bmatrix}, \quad (3)$$

multiply through to obtain

$$\begin{bmatrix} a_{11}\lambda_1 & \cdots & a_{1n}\lambda_n \\ \vdots & \ddots & \vdots \\ a_{n1}\lambda_1 & \cdots & a_{nn}\lambda_n \end{bmatrix} = \begin{bmatrix} a_{11}\lambda_1 & \cdots & a_{1n}\lambda_1 \\ \vdots & \ddots & \vdots \\ a_{n1}\lambda_n & \cdots & a_{nn}\lambda_n \end{bmatrix}. \quad (4)$$

Since in general,  $\lambda_i \neq \lambda_j$  for  $i \neq j$ , this can be true only if off-diagonal components vanish. Therefore,  $A$  must be diagonal.

Given a diagonal matrix  $T$ ,

$$T^n = \begin{bmatrix} t_1 & 0 & \cdots & 0 \\ 0 & t_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & t_k \end{bmatrix}^n = \begin{bmatrix} t_1^n & 0 & \cdots & 0 \\ 0 & t_2^n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & t_k^n \end{bmatrix}. \quad (5)$$

**Diagonal Metric**

A METRIC  $g_{ij}$  which is zero for  $i \neq j$ .

see also METRIC

**Diagonal (Polygon)**

A LINE SEGMENT connecting two nonadjacent VERTICES of a POLYGON. The number of ways a fixed convex  $n$ -gon can be divided into TRIANGLES by nonintersecting diagonals is  $C_{n-2}$  (with  $C_{n-3}$  diagonals), where  $C_n$  is a CATALAN NUMBER. This is EULER'S POLYGON DIVISION PROBLEM. Counting the number of regions determined by drawing the diagonals of a regular  $n$ -gon is a more difficult problem, as is determining the number of  $n$ -tuples of CONCURRENT diagonals (Beller *et al.* 1972, Item 2).

The number of regions which the diagonals of a CONVEX POLYGON divide its center if no three are concurrent in its interior is

$$N = \binom{n}{4} + \binom{n-1}{2} = \frac{1}{24}(n-1)(n-2)(n^2-3n+12).$$

The first few values are 0, 0, 1, 4, 11, 25, 50, 91, 154, 246, ... (Sloane's A006522).

#### References

Eppstein, D. "Width, Diameter, and Geometric Inequalities." <http://www.ics.uci.edu/~eppstein/junkyard/diam.html>.

### Diameter (Graph)

The length of the "longest shortest path" between two VERTICES of a GRAPH. In other words, a graph's diameter is the largest number of vertices which must be traversed in order to travel from one vertex to another when paths which backtrack, detour, or loop are excluded from consideration.

### Diamond

A convex QUADRILATERAL having sides of equal length and PERPENDICULAR PLANES of symmetry passing through opposite pairs of VERTICES. The LOZENGE is a special case of a diamond.

see also KITE, LOZENGE, PARALLELOGRAM, QUADRILATERAL, RHOMBUS

### Dice

A die (plural "dice") is a SOLID with markings on each of its faces. The faces are usually all the same shape, making PLATONIC SOLIDS and ARCHIMEDEAN SOLID DUALS the obvious choices. The die can be "rolled" by throwing it in the air and allowing it to come to rest on one of its faces. Dice are used in many games of chance as a way of picking RANDOM NUMBERS on which to bet, and are used in board or roll-playing games to determine the number of spaces to move, results of a conflict, etc. A COIN can be viewed as a degenerate 2-sided case of a die.

The most common type of die is a six-sided CUBE with the numbers 1–6 placed on the faces. The value of the roll is indicated by the number of "spots" showing on the top. For the six-sided die, opposite faces are arranged to always sum to seven. This gives two possible MIRROR IMAGE arrangements in which the numbers 1, 2, and 3 may be arranged in a clockwise or counterclockwise order about a corner. Commercial dice may, in fact, have either orientation. The illustrations below show 6-sided dice with counterclockwise and clockwise arrangements, respectively.

The CUBE has the nice property that there is an upward-pointing face opposite the bottom face from which the value of the "roll" can easily be read. This would not be true, for instance, for a TETRAHEDRAL die, which would have to be picked up and turned over to reveal the number underneath (although it could be determined by noting which number 1-4 was *not* visible on one of the upper three faces). The arrangement of spots  $\begin{smallmatrix} \bullet & \bullet \\ \bullet & \bullet \end{smallmatrix}$  corresponding to a roll of 5 on a six-sided die is called the QUINCUNX. There are also special names for certain rolls of two six-sided dice: two 1s are called SNAKE EYES and two 6s are called BOXCARS.

Shapes of dice other than the usual 6-sided CUBE are commercially available from companies such as Dice & Games, Ltd.<sup>®</sup>

Diaconis and Keller (1989) show that there exist "fair" dice other than the usual PLATONIC SOLIDS and duals of the ARCHIMEDEAN SOLIDS, where a fair die is one for which its symmetry group acts transitively on its faces. However, they did not explicitly provide any examples.

The probability of obtaining  $p$  points (a roll of  $p$ ) on  $n$   $s$ -sided dice can be computed as follows. The number of ways in which  $p$  can be obtained is the COEFFICIENT of  $x^p$  in

$$f(x) = (x + x^2 + \dots + x^s)^n, \quad (1)$$

since each possible arrangement contributes one term.  $f(x)$  can be written as a MULTINOMIAL SERIES

$$f(x) = x^n \left( \sum_{i=0}^{s-1} x^i \right)^n = x^n \left( \frac{1-x^s}{1-x} \right)^n, \quad (2)$$

so the desired number  $c$  is the COEFFICIENT of  $x^p$  in

$$x^n (1-x^s)^n (1-x)^{-n}. \quad (3)$$

Expanding,

$$x^n \sum_{k=0}^n (-1)^k \binom{n}{k} x^{sk} \sum_{l=0}^{\infty} \binom{n+l-1}{l} x^l, \quad (4)$$

so in order to get the COEFFICIENT of  $x^p$ , include all terms with

$$p = n + sk + l. \quad (5)$$

$c$  is therefore

$$c = \sum_{k=0}^n (-1)^k \binom{n}{k} \binom{p-sk-1}{p-sk-n}. \quad (6)$$

But  $p-sk-n > 0$  only when  $k < (p-n)/s$ , so the other terms do not contribute. Furthermore,

$$\binom{p-sk-1}{p-sk-n} = \binom{p-sk-1}{n-1}, \quad (7)$$

so

$$c = \sum_{k=0}^{\lfloor (p-n)/s \rfloor} (-1)^k \binom{n}{k} \binom{p-sk-1}{n-1}, \quad (8)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, and

$$P(p, n, s) = \frac{1}{s^n} \sum_{k=0}^{\lfloor (p-n)/s \rfloor} (-1)^k \binom{n}{k} \binom{p-sk-1}{n-1}. \quad (9)$$

Consider now  $s = 6$ . For  $n = 2$  six-sided dice,

$$k_{\max} \equiv \left\lfloor \frac{p-2}{6} \right\rfloor = \begin{cases} 0 & \text{for } 2 \leq p \leq 7 \\ 1 & \text{for } 12 \leq p \leq 8, \end{cases} \quad (10)$$

and

$$\begin{aligned} P(p, 2, 6) &= \frac{1}{6^2} \sum_{k=0}^{k_{\max}} (-1)^k \binom{2}{k} \binom{p-6k-1}{1} \\ &= \frac{1}{6^2} \sum_{k=0}^{k_{\max}} (-1)^k \frac{2!}{k!(2-k)!} (p-6k-1) \\ &= \frac{1}{36} \sum_{k=0}^{k_{\max}} (1-2k)(k+1)(p-6k-1) \\ &= \frac{1}{36} \begin{cases} p-1 & \text{for } 2 \leq p \leq 7 \\ 13-p & \text{for } 8 \leq p \leq 12 \end{cases} \\ &= \frac{6-|p-7|}{36} \quad \text{for } 2 \leq p \leq 12. \end{aligned} \quad (11)$$

The most common roll is therefore seen to be a 7, with probability  $6/36 = 1/6$ , and the least common rolls are 2 and 12, both with probability  $1/36$ .

For  $n = 3$  six-sided dice,

$$k_{\max} = \left\lfloor \frac{p-3}{6} \right\rfloor = \begin{cases} 0 & \text{for } 3 \leq p \leq 8 \\ 1 & \text{for } 9 \leq p \leq 14 \\ 2 & \text{for } 15 \leq p \leq 18, \end{cases} \quad (12)$$

and

$$\begin{aligned} P(p, 3, 6) &= \frac{1}{6^3} \sum_{k=0}^{k_{\max}} (-1)^k \binom{3}{k} \binom{p-6k-1}{2} \\ &= \frac{1}{6^3} \sum_{k=0}^{k_{\max}} (-1)^k \frac{3!}{k!(3-k)!} \frac{(p-6k-1)(p-6k-2)}{2} \\ &= \frac{1}{216} \begin{cases} \frac{(p-1)(p-2)}{2} & \text{for } 3 \leq p \leq 8 \\ \frac{(p-1)(p-2)}{2} - 3 \frac{(p-7)(p-8)}{2} & \text{for } 9 \leq p \leq 14 \\ \frac{(p-1)(p-2)}{2} - 3 \frac{(p-7)(p-8)}{2} + 3 \frac{(p-13)(p-14)}{2} & \text{for } 15 \leq p \leq 18 \end{cases} \\ &= \frac{1}{216} \begin{cases} \frac{1}{2}(p-1)(p-2) & \text{for } 3 \leq p \leq 8 \\ -p^2 + 21p - 83 & \text{for } 9 \leq p \leq 14 \\ \frac{1}{2}(19-p)(20-p) & \text{for } 15 \leq p \leq 18. \end{cases} \end{aligned} \quad (13)$$

For three six-sided dice, the most common rolls are 10 and 11, both with probability  $1/8$ ; and the least common rolls are 3 and 18, both with probability  $1/216$ .

For four six-sided dice, the most common roll is 14, with probability 73/648; and the least common rolls are 4 and 24, both with probability 1/1296.

In general, the likeliest roll  $p_L$  for  $n$   $s$ -sided dice is given by

$$p_L(n, s) = \left\lfloor \frac{1}{2}n(s+1) \right\rfloor, \quad (14)$$

which can be written explicitly as

$$p_L(n, s) = \begin{cases} \frac{1}{2}n(s+1) & \text{for } n \text{ even} \\ \frac{1}{2}[n(s+1) - 1] & \text{for } n \text{ odd, } s \text{ even} \\ \frac{1}{2}n(s+1) & \text{for } n \text{ odd, } s \text{ odd.} \end{cases} \quad (15)$$

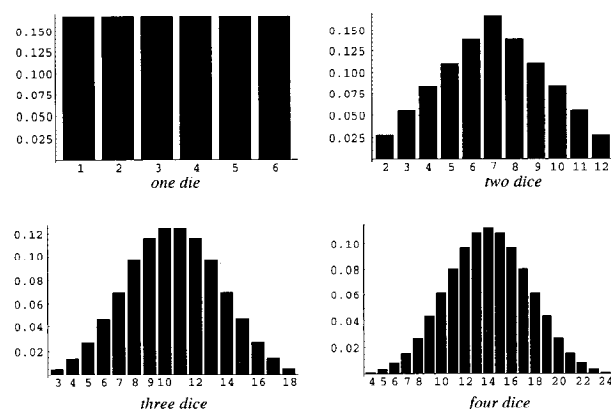

For 6-sided dice, the likeliest rolls are given by

$$p_L(n, 6) = \left\lfloor \frac{7}{2}n \right\rfloor = \begin{cases} \frac{7}{2}n & \text{for } n \text{ even} \\ \frac{7}{2}(7n-1) & \text{for } n \text{ odd, } s \text{ even} \\ \frac{7}{2}n & \text{for } n \text{ odd, } s \text{ odd,} \end{cases} \quad (16)$$

or 7, 10, 14, 17, 21, 24, 28, 31, 35, ... for  $n = 2, 3, \dots$  (Sloane's A030123) dice. The probabilities corresponding to the most likely rolls can be computed by plugging  $p = p_L$  into the general formula together with

$$k_L(n, s) = \begin{cases} \frac{1}{2}n & \text{for } n \text{ even} \\ \left\lfloor \frac{n(s-1)-1}{2s} \right\rfloor & \text{for } n \text{ odd, } s \text{ even} \\ \left\lfloor \frac{n(s-1)}{2s} \right\rfloor & \text{for } n \text{ odd, } s \text{ odd.} \end{cases} \quad (17)$$

Unfortunately,  $P(p_L, n, s)$  does not have a simple closed-form expression in terms of  $s$  and  $n$ . However, the probabilities of obtaining the likeliest roll totals can be found explicitly for a particular  $s$ . For  $n$  6-sided dice, the probabilities are 1/6, 1/8, 73/648, 65/648, 361/3888, 24017/279936, 7553/93312, ... for  $n = 2, 3, \dots$

The probabilities for obtaining a given total using  $n$  6-sided dice are shown above for  $n = 1, 2, 3$ , and 4 dice. They can be seen to approach a GAUSSIAN DISTRIBUTION as the number of dice is increased.

## Dichroic Polynomial

A POLYNOMIAL  $Z_G(q, v)$  in two variables for abstract GRAPHS. A GRAPH with one VERTEX has  $Z = q$ . Adding a VERTEX not attached by any EDGES multiplies the  $Z$  by  $q$ . Picking a particular EDGE of a GRAPH  $G$ , the POLYNOMIAL for  $G$  is defined by adding the POLYNOMIAL of the GRAPH with that EDGE deleted to  $v$  times the POLYNOMIAL of the graph with that EDGE collapsed to a point. Setting  $v = -1$  gives the number of distinct VERTEX colorings of the GRAPH. The dichroic POLYNOMIAL of a PLANAR GRAPH can be expressed as the SQUARE BRACKET POLYNOMIAL of the corresponding ALTERNATING LINK by

$$Z_G(q, v) = q^{N/2} B_{L(G)},$$

where  $N$  is the number of VERTICES in  $G$ . Dichroic POLYNOMIALS for some simple GRAPHS are

$$\begin{aligned} Z_{K_1} &= q \\ Z_{K_2} &= q^2 + vq \\ Z_{K_3} &= q^3 + 3vq^2 + 3v^2q + v^3q. \end{aligned}$$

## Dido's Problem

Find the figure bounded by a line which has the maximum AREA for a given PERIMETER. The solution is a SEMICIRCLE.

see also ISOPERIMETRIC PROBLEM, ISOVOLUME PROBLEM, PERIMETER, SEMICIRCLE

## Diesis

The musical interval by which an octave exceeds three major thirds,

$$\frac{2}{\left(\frac{5}{4}\right)^3} = \frac{2^7}{5^3} = \frac{128}{125} = 1.024.$$

Taking CONTINUED FRACTION CONVERGENTS of  $\log(5/4)/\log(2)$  gives the increasing accurate approximations  $m/n$  of  $m$  octaves and  $n$  major thirds: 1/3,

9/28, 19/59, 47/146, 207/643, 1289/4004, ... (Sloane's A046103 and A046104). Other near equalities of  $m$  octaves and  $n$  major thirds having

$$R \equiv \frac{2^m}{\left(\frac{5}{4}\right)^n} = \frac{2^{m+2n}}{5^n}$$

with  $|R - 1| < 0.02$  are given in the following table.

$m$	$n$	Ratio	$m$	$n$	Ratio

### Diffeomorphism

A diffeomorphism is a MAP between MANIFOLDS which is DIFFERENTIABLE and has a DIFFERENTIABLE inverse.

see also ANOSOV DIFFEOMORPHISM, AXIOM A DIFFEOMORPHISM, SYMPLECTIC DIFFEOMORPHISM, TANGENT MAP

### Difference

The difference of two numbers  $n_1$  and  $n_2$  is  $n_1 - n_2$ , where the MINUS sign denotes SUBTRACTION.

see also BACKWARD DIFFERENCE, FINITE DIFFERENCE, FORWARD DIFFERENCE

### Difference Equation

A difference equation is the discrete analogue of a DIFFERENTIAL EQUATION. A difference equation involves a FUNCTION with INTEGER-valued arguments  $f(n)$  in a form like

$$f(n) - f(n-1) = g(n), \quad (1)$$

where  $g$  is some FUNCTION. The above equation is the discrete analog of the first-order ORDINARY DIFFERENTIAL EQUATION

$$f'(x) = g(x). \quad (2)$$

Examples of difference equations often arise in DYNAMICAL SYSTEMS. Examples include the iteration involved in the MANDELBROT and JULIA SET definitions,

$$f(n+1) = f(n)^2 + c, \quad (3)$$

with  $c$  a constant, as well as the LOGISTIC EQUATION

$$f(n+1) = rf(n)[1 - f(n)], \quad (4)$$

with  $r$  a constant.

see also FINITE DIFFERENCE, RECURRENCE RELATION

### Difference Operator

see BACKWARD DIFFERENCE, FORWARD DIFFERENCE

### Difference Quotient

$$\Delta_h f(x) \equiv \frac{f(x+h) - f(x)}{h} = \frac{\Delta f}{h}.$$

It gives the slope of the SECANT LINE passing through  $f(x)$  and  $f(x+h)$ . In the limit  $h \rightarrow 0$ , the difference quotient becomes the PARTIAL DERIVATIVE

$$\lim_{h \rightarrow 0} \Delta_{x(h)} f(x, y) = \frac{\partial f}{\partial x}.$$

### Difference Set

Let  $G$  be a GROUP of ORDER  $h$  and  $D$  be a set of  $k$  elements of  $G$ . If the set of differences  $d_i - d_j$  contains every NONZERO element of  $G$  exactly  $\lambda$  times, then  $D$  is a  $(h, k, \lambda)$ -difference set in  $G$  of ORDER  $n = k - \lambda$ . If  $\lambda = 1$ , the difference set is called planar. The quadratic residues in the GALOIS FIELD  $GF(11)$  form a difference set. If there is a difference set of size  $k$  in a group  $G$ , then  $2\binom{k}{2}$  must be a multiple of  $|G| - 1$ , where  $\binom{k}{2}$  is a BINOMIAL COEFFICIENT.

#### References

Gordon, D. M. "The Prime Power Conjecture is True for  $n < 2,000,000$ ." *Electronic J. Combinatorics* 1, R6, 1-7, 1994. <http://www.combinatorics.org/Volume1/volume1.html#R6>.

**Difference of Successes**

If  $x_1/n_1$  and  $x_2/n_2$  are the observed proportions from standard NORMALLY DISTRIBUTED samples with proportion of success  $\theta$ , then the probability that

$$w \equiv \frac{x_1}{n_1} - \frac{x_2}{n_2} \quad (1)$$

will be as great as observed is

$$P_\delta = 1 - 2 \int_0^{|\delta|} \phi(t) dt, \quad (2)$$

where

$$\delta \equiv \frac{w}{\sigma_w} \quad (3)$$

$$\sigma_w \equiv \sqrt{\hat{\theta}(1-\hat{\theta}) \left( \frac{1}{n_1} + \frac{1}{n_2} \right)} \quad (4)$$

$$\hat{\theta} \equiv \frac{x_1 + x_2}{n_1 + n_2}. \quad (5)$$

Here,  $\hat{\theta}$  is the UNBIASED ESTIMATOR. The SKEWNESS and KURTOSIS of this distribution are

$$\gamma_1^2 = \frac{(n_1 - n_2)^2}{n_1 n_2 (n_1 + n_2)} \frac{1 - 4\hat{\theta}(1-\hat{\theta})}{\hat{\theta}(1-\hat{\theta})} \quad (6)$$

$$\gamma_2 = \frac{n_1^2 - n_1 n_2 + n_2^2}{n_1 n_2 (n_1 + n_2)} \frac{1 - 6\hat{\theta}(1-\hat{\theta})}{\hat{\theta}(1-\hat{\theta})}. \quad (7)$$

**Difference Table**

A table made by subtracting adjacent entries in a sequence, then repeating the process with those numbers.

see also FINITE DIFFERENCE, QUOTIENT-DIFFERENCE TABLE

**Different**

Two quantities are said to be different (or "unequal") if they are not EQUAL.

The term "different" also has a technical usage related to MODULES. Let a MODULE  $M$  in an INTEGRAL DOMAIN  $D_1$  for  $R(\sqrt{D})$  be expressed using a two-element basis as

$$M = [\xi_1, \xi_2],$$

where  $\xi_1$  and  $\xi_2$  are in  $D_1$ . Then the different of the MODULE is defined as

$$\Delta = \Delta(M) = \begin{vmatrix} \xi_1 & \xi_2 \\ \xi_1' & \xi_2' \end{vmatrix} = \xi_1 \xi_2' - \xi_1' \xi_2.$$

The different  $\Delta \neq 0$  IFF  $\xi_1$  and  $\xi_2$  are linearly independent. The DISCRIMINANT is defined as the square of the different.

see also DISCRIMINANT (MODULE), EQUAL, MODULE

**References**

Cohn, H. *Advanced Number Theory*. New York: Dover, pp. 72-73, 1980.

**Different Prime Factors**

see DISTINCT PRIME FACTORS

**Differentiable**

A FUNCTION is said to be differentiable at a point if its DERIVATIVE exists at that point. Let  $z = x + iy$  and  $f(z) = u(x, y) + iv(x, y)$  on some region  $G$  containing the point  $z_0$ . If  $f(z)$  satisfies the CAUCHY-RIEMANN EQUATIONS and has continuous first PARTIAL DERIVATIVES at  $z_0$ , then  $f'(z_0)$  exists and is given by

$$f'(z_0) = \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0},$$

and the function is said to be COMPLEX DIFFERENTIABLE. Amazingly, there exist CONTINUOUS FUNCTIONS which are nowhere differentiable. Two examples are the BLANCMANGE FUNCTION and WEIERSTRASS FUNCTION.

**Differentiable Manifold**

see SMOOTH MANIFOLD

**Differential**

A DIFFERENTIAL 1-FORM.

see also EXACT DIFFERENTIAL, INEXACT DIFFERENTIAL

**Differential Calculus**

That portion of "the" CALCULUS dealing with DERIVATIVES.

see also INTEGRAL CALCULUS

**Differential Equation**

An equation which involves the DERIVATIVES of a function as well as the function itself. If PARTIAL DERIVATIVES are involved, the equation is called a PARTIAL DIFFERENTIAL EQUATION; if only ordinary DERIVATIVES are present, the equation is called an ORDINARY DIFFERENTIAL EQUATION. Differential equations play an extremely important and useful role in applied math, engineering, and physics, and much mathematical and numerical machinery has been developed for the solution of differential equations.

## Differential $k$ -Form

A differential  $k$ -form is a TENSOR of RANK  $k$  which is antisymmetric under exchange of any pair of indices. The number of algebraically independent components in  $n$ -D is  $\binom{n}{k}$ , where this is a BINOMIAL COEFFICIENT. In particular, a 1-form (often simply called a "differential") is a quantity

$$\omega^1 = b_1 dx_1 + b_2 dx_2, \quad (1)$$

where  $b_1 = b_1(x_1, x_2)$  and  $b_2 = b_2(x_1, x_2)$  are the components of a COVARIANT TENSOR. Changing variables from  $\mathbf{x}$  to  $\mathbf{y}$  gives

$$\omega^1 = \sum_{i=1}^2 b_i dx_i = \sum_{i=1}^2 \sum_{j=1}^2 b_i \frac{\partial x_i}{\partial y_j} = \sum_{j=1}^2 \bar{b}_j dy_j, \quad (2)$$

where

$$\bar{b}_j \equiv \sum_{i=1}^2 b_i \frac{\partial x_i}{\partial y_j}, \quad (3)$$

which is the covariant transformation law. 2-forms can be constructed from the WEDGE PRODUCT of 1-forms. Let

$$\theta_1 \equiv b_1 dx_1 + b_2 dx_2 \quad (4)$$

$$\theta_2 \equiv c_1 dx_1 + c_2 dx_2, \quad (5)$$

then  $\theta_1 \wedge \theta_2$  is a 2-form denoted  $\omega^2$ . Changing variables  $x_1(y_1, y_2)$  to  $x_2(y_1, y_2)$  gives

$$dx_1 = \frac{\partial x_1}{\partial y_1} dy_1 + \frac{\partial x_1}{\partial y_2} dy_2 \quad (6)$$

$$dx_2 = \frac{\partial x_2}{\partial y_1} dy_1 + \frac{\partial x_2}{\partial y_2} dy_2, \quad (7)$$

so

$$\begin{aligned} dx_1 \wedge dx_2 &= \left( \frac{\partial x_1}{\partial y_1} \frac{\partial x_2}{\partial y_2} - \frac{\partial x_1}{\partial y_2} \frac{\partial x_2}{\partial y_1} \right) dy_1 \wedge dy_2 \\ &= \frac{\partial(x_1, x_2)}{\partial(y_1, y_2)} dy_1 \wedge dy_2. \end{aligned} \quad (8)$$

Similarly, a 4-form can be constructed from WEDGE PRODUCTS of two 2-forms or four 1-forms

$$\omega^4 = \omega_1^2 \wedge \omega_2^2 = (\omega_1^1 \wedge \omega_2^1) \wedge (\omega_3^1 \wedge \omega_4^1). \quad (9)$$

## Differentiation

The computation of a DERIVATIVE.

see also CALCULUS, DERIVATIVE, INTEGRAL, INTEGRATION

## Digamma Function

Two notations are used for the digamma function. The  $\Psi(z)$  digamma function is defined by

$$\Psi(z) \equiv \frac{d}{dz} \ln \Gamma(z) = \frac{\Gamma'(z)}{\Gamma(z)}, \quad (1)$$

where  $\Gamma$  is the GAMMA FUNCTION, and is the function returned by the function `PolyGamma[z]` in *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL). The  $F$  digamma function is defined by

$$F(z) \equiv \frac{d}{dz} \ln z! \quad (2)$$

and is equal to

$$F(z) = \Psi(z+1). \quad (3)$$

From a series expansion of the FACTORIAL function,

$$\begin{aligned} F(z) &= \frac{d}{dz} \lim_{n \rightarrow \infty} [\ln n! + z \ln n \\ &\quad - \ln(z+1) - \ln(z+2) - \dots - \ln(z+n)] \quad (4) \\ &= \lim_{n \rightarrow \infty} \left( \ln n - \frac{1}{z+1} - \frac{1}{z+2} - \dots - \frac{1}{z+n} \right) \quad (5) \end{aligned}$$

$$= -\gamma - \sum_{n=1}^{\infty} \left( \frac{1}{z+n} - \frac{1}{n} \right) \quad (6)$$

$$= -\gamma + \sum_{n=1}^{\infty} \frac{z}{n(n+z)} \quad (7)$$

$$= \ln z + \frac{1}{2z} - \sum_{n=1}^{\infty} \frac{B_{2n}}{2nz^{2n}}, \quad (8)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $B_{2n}$  are BERNOULLI NUMBERS.

The  $n$ th DERIVATIVE of  $\Psi(z)$  is called the POLYGAMMA FUNCTION and is denoted  $\psi_n(z)$ . Since the digamma

function is the zeroth derivative of  $\Psi(z)$  (i.e., the function itself), it is also denoted  $\psi_0(z)$ .

The digamma function satisfies

$$\Psi(z) = \int_0^{\infty} \left( \frac{e^{-t}}{t} - \frac{e^{-zt}}{1-e^{-t}} \right) dt. \quad (9)$$

For integral  $z \equiv n$ ,

$$\Psi(n) = -\gamma + \sum_{k=1}^{n-1} \frac{1}{k} = -\gamma + H_{n-1}, \quad (10)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $H_n$  is a HARMONIC NUMBER. Other identities include

$$\frac{d\Psi}{dz} = \sum_{n=0}^{\infty} \frac{1}{(z+n)^2} \quad (11)$$

$$\Psi(1-z) - \Psi(z) = \pi \cot(\pi z) \quad (12)$$

$$\Psi(z+1) = \Psi(z) + \frac{1}{z} \quad (13)$$

$$\Psi(2z) = \frac{1}{2}\Psi(z) + \frac{1}{2}\Psi\left(z + \frac{1}{2}\right) + \ln 2. \quad (14)$$

Special values are

$$\Psi\left(\frac{1}{2}\right) = -\gamma - 2 \ln 2 \quad (15)$$

$$\Psi(1) = -\gamma. \quad (16)$$

At integral values,

$$\psi_0(n+1) = -\gamma + \sum_{k=1}^n \frac{1}{k}, \quad (17)$$

and at half-integral values,

$$\psi_0\left(\frac{1}{2} \pm n\right) = -\ln(4\gamma) + 2 \sum_{k=1}^n \frac{1}{2k-1}. \quad (18)$$

At rational arguments,  $\psi_0(p/q)$  is given by the explicit equation

$$\begin{aligned} \psi_0\left(\frac{p}{q}\right) &= -\gamma - \ln(2q) - \frac{1}{2}\pi \cot\left(\frac{p}{q}\pi\right) \\ &\quad + 2 \sum_{k=1}^{\lceil q/2 \rceil - 1} \cos\left(\frac{2\pi pk}{q}\right) \ln\left[\sin\left(\frac{\pi k}{q}\right)\right] \quad (19) \end{aligned}$$

for  $0 < p < q$  (Knuth 1973). These give the special values

$$\psi_0\left(\frac{1}{2}\right) = -\gamma - 2 \ln 2 \quad (20)$$

$$\psi_0\left(\frac{1}{3}\right) = \frac{1}{6}(-6\gamma - \pi\sqrt{3} - 9 \ln 3) \quad (21)$$

$$\psi_0\left(\frac{2}{3}\right) = \frac{1}{6}(-6\gamma + \pi\sqrt{3} - 9 \ln 3) \quad (22)$$

$$\psi_0\left(\frac{1}{4}\right) = -\gamma - \frac{1}{2}\pi - 3 \ln 2 \quad (23)$$

$$\psi_0\left(\frac{3}{4}\right) = \frac{1}{2}(-2\gamma + \pi - 6 \ln 2) \quad (24)$$

$$\psi_0(1) = -\gamma, \quad (25)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT. Sums and differences of  $\psi_1(r/s)$  for small integral  $r$  and  $s$  can be expressed in terms of CATALAN'S CONSTANT and  $\pi$ .

### Digimetic

A CRYPTARITHM in which DIGITS are used to represent other DIGITS.

### Digit

The number of digits  $D$  in an INTEGER  $n$  is the number of numbers in some base (usually 10) required to represent it. The numbers 1 to 9 are therefore single digits, while the numbers 10 to 99 are double digits. Terms such as "double-digit inflation" are occasionally encountered, although this particular usage has thankfully not been needed in the U.S. for some time. The number of (base 10) digits in a number  $n$  can be calculated as

$$D = \lfloor \log_{10} n + 1 \rfloor,$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION.

see also 196-ALGORITHM, ADDITIVE PERSISTENCE, DIGITADITION, DIGITAL ROOT, FACTORION, FIGURES, LENGTH (NUMBER), MULTIPLICATIVE PERSISTENCE, NARCISSISTIC NUMBER, SCIENTIFIC NOTATION, SIGNIFICANT DIGITS, SMITH NUMBER

### Digitadition

Start with an INTEGER  $n$ , known as the GENERATOR. Add the SUM of the GENERATOR's digits to the GENERATOR to obtain the digitadition  $n'$ . A number can have more than one GENERATOR. If a number has no GENERATOR, it is called a SELF NUMBER. The sum of all numbers in a digitadition series is given by the last term minus the first plus the sum of the DIGITS of the last.

If the digitadition process is performed on  $n'$  to yield its digitadition  $n''$ , on  $n''$  to yield  $n'''$ , etc., a single-digit number, known as the DIGITAL ROOT of  $n$ , is eventually obtained. The digital roots of the first few integers are 1, 2, 3, 4, 5, 6, 7, 8, 9, 1, 2, 3, 4, 5, 6, 7, 9, 1, ... (Sloane's A010888).

If the process is generalized so that the  $k$ th (instead of first) powers of the digits of a number are repeatedly added, a periodic sequence of numbers is eventually obtained for any given starting number  $n$ . If the original number  $n$  is equal to the sum of the  $k$ th powers of its digits, it is called a NARCISSISTIC NUMBER. If the original number is the smallest number in the eventually periodic sequence of numbers in the repeated  $k$ -digitaditions, it is called a RECURRING DIGITAL INVARIANT. Both NARCISSISTIC NUMBERS and RECURRING DIGITAL INVARIANTS are relatively rare.

The only possible periods for repeated 2-digitaditions are 1 and 8, and the periods of the first few positive integers are 1, 8, 8, 8, 8, 8, 1, 8, 8, 1, ... The possible periods  $p$  for  $n$ -digitaditions are summarized in the following table, together with digitaditions for the first few integers and the corresponding sequence numbers.

$n$	Sloane	$ps$	$n$ -Digitaditions
2	031176	1, 8	1, 8, 8, 8, 8, 8, 1, 8, 8, ...
3	031178	1, 2, 3	1, 1, 1, 3, 1, 1, 1, 1, 1, ...
4	031182	1, 2, 7	1, 7, 7, 7, 7, 7, 7, 7, 7, ...
5	031186	1, 2, 4, 6, 10, 12, 22, 28	1, 12, 22, 4, 10, 22, 28, 10, 22, 1, ...
6	031195	1, 2, 3, 4, 10, 30	1, 10, 30, 30, 30, 10, 10, 10, 3, 1, 10, ...
7	031200	1, 2, 3, 6, 12, 14, 21, 27, 30, 56, 92	1, 92, 14, 30, 92, 56, 6, 92, 56, 1, 92, 27, ...

NARCISSISTIC NUMBER, RECURRING DIGITAL INVARIANT

### Digital Root

Consider the process of taking a number, adding its DIGITS, then adding the DIGITS of numbers derived from it, etc., until the remaining number has only one DIGIT. The number of additions required to obtain a single DIGIT from a number  $n$  is called the ADDITIVE PERSISTENCE of  $n$ , and the DIGIT obtained is called the digital root of  $n$ .

For example, the sequence obtained from the starting number 9876 is (9876, 30, 3), so 9876 has an ADDITIVE PERSISTENCE of 2 and a digital root of 3. The digital roots of the first few integers are 1, 2, 3, 4, 5, 6, 7, 8, 9, 1, 2, 3, 4, 5, 6, 7, 9, 1, ... (Sloane's A010888). The digital root of an INTEGER  $n$  can therefore be computed without actually performing the iteration using the simple congruence formula

$$\begin{cases} n \pmod{9} & n \not\equiv 0 \pmod{9} \\ 9 & n \equiv 0 \pmod{9}. \end{cases}$$

### Dilemma

Informally, a situation in which a decision must be made from several alternatives, none of which is obviously the optimal one. In formal LOGIC, a dilemma is a specific type of argument using two conditional statements which may take the form of a CONSTRUCTIVE DILEMMA or a DESTRUCTIVE DILEMMA.

see also CONSTRUCTIVE DILEMMA, DESTRUCTIVE DILEMMA, MONTY HALL PROBLEM, PARADOX, PRISONER'S DILEMMA

### Dilogarithm

A special case of the POLYLOGARITHM  $\text{Li}_n(z)$  for  $n = 2$ . It is denoted  $\text{Li}_2(z)$ , or sometimes  $L_2(z)$ , and is defined by the sum

$$\text{Li}_2(z) = \sum_{k=1}^{\infty} \frac{z^k}{k^2}$$

or the integral

$$\text{Li}_2(z) \equiv \int_z^0 \frac{\ln(1-t) dt}{t}.$$

There are several remarkable identities involving the POLYLOGARITHM function.

### Dilworth's Lemma

The WIDTH of a set  $P$  is equal to the minimum number of CHAINS needed to COVER  $P$ . Equivalently, if a set  $P$  of  $ab + 1$  elements is PARTIALLY ORDERED, then  $P$  contains a CHAIN of size  $a + 1$  or an ANTICHAIN of size  $b + 1$ . Letting  $N$  be the CARDINALITY of  $P$ ,  $W$  the WIDTH, and  $L$  the LENGTH, this last statement says  $N \leq LW$ . Dilworth's lemma is a generalization of the ERDŐS-SZEKERES THEOREM. RAMSEY'S THEOREM generalizes Dilworth's Lemma.

### Dilworth's Theorem

see DILWORTH'S LEMMA

### Dimension

The notion of dimension is important in mathematics because it gives a precise parameterization of the conceptual or visual complexity of any geometric object. In fact, the concept can even be applied to abstract objects which cannot be directly visualized. For example, the notion of time can be considered as one-dimensional, since it can be thought of as consisting of only "now," "before" and "after." Since "before" and "after," regardless of how far back or how far into the future they are, are extensions, time is like a line, a 1-dimensional object.

To see how lower and higher dimensions relate to each other, take any geometric object (like a POINT, LINE, CIRCLE, PLANE, etc.), and "drag" it in an opposing direction (drag a POINT to trace out a LINE, a LINE to trace out a box, a CIRCLE to trace out a CYLINDER, a DISK to a solid CYLINDER, etc.). The result is an object which is qualitatively "larger" than the previous object, "qualitative" in the sense that, regardless of how you drag the original object, you always trace out an object of the same "qualitative size." The POINT could be made into a straight LINE, a CIRCLE, a HELIX, or some other CURVE, but all of these objects are qualitatively of the same dimension. The notion of dimension was invented for the purpose of measuring this "qualitative" topological property.

Making things a bit more formal, finite collections of objects (e.g., points in space) are considered 0-dimensional. Objects that are "dragged" versions of 0-dimensional objects are then called 1-dimensional. Similarly, objects which are dragged 1-dimensional objects are 2-dimensional, and so on. Dimension is formalized in

mathematics as the intrinsic dimension of a TOPOLOGICAL SPACE. This dimension is called the LEBESGUE COVERING DIMENSION (also known simply as the TOPOLOGICAL DIMENSION). The archetypal example is EUCLIDEAN  $n$ -space  $\mathbb{R}^n$ , which has topological dimension  $n$ . The basic ideas leading up to this result (including the DIMENSION INVARIANCE THEOREM, DOMAIN INVARIANCE THEOREM, and LEBESGUE COVERING DIMENSION) were developed by Poincaré, Brouwer, Lebesgue, Urysohn, and Menger.

There are several branchings and extensions of the notion of topological dimension. Implicit in the notion of the LEBESGUE COVERING DIMENSION is that dimension, in a sense, is a measure of how an object fills space. If it takes up a lot of room, it is higher dimensional, and if it takes up less room, it is lower dimensional. HAUSDORFF DIMENSION (also called FRACTAL DIMENSION) is a fine tuning of this definition that allows notions of objects with dimensions other than INTEGERS. FRACTALS are objects whose HAUSDORFF DIMENSION is different from their TOPOLOGICAL DIMENSION.

The concept of dimension is also used in ALGEBRA, primarily as the dimension of a VECTOR SPACE over a FIELD. This usage stems from the fact that VECTOR SPACES over the reals were the first VECTOR SPACES to be studied, and for them, their topological dimension can be calculated by purely algebraic means as the CARDINALITY of a maximal linearly independent subset. In particular, the dimension of a SUBSPACE of  $\mathbb{R}^n$  is equal to the number of LINEARLY INDEPENDENT VECTORS needed to generate it (i.e., the number of VECTORS in its BASIS). Given a transformation  $A$  of  $\mathbb{R}^n$ ,

$$\dim[\text{Range}(A)] + \dim[\text{Null}(A)] = \dim(\mathbb{R}^n).$$

#### Dimension Axiom

One of the EILENBERG-STEENROD AXIOMS. Let  $X$  be a single point space.  $H_n(X) = 0$  unless  $n = 0$ , in which case  $H_0(X) = G$  where  $G$  are some GROUPS. The  $H_0$  are called the COEFFICIENTS of the HOMOLOGY THEORY  $H(\cdot)$ .

see also EILENBERG-STEENROD AXIOMS, HOMOLOGY (TOPOLOGY)

#### Dimension Invariance Theorem

$\mathbb{R}^n$  is HOMEOMORPHIC to  $\mathbb{R}^m$  IFF  $n = m$ . This theorem was first proved by Brouwer.

see also DOMAIN INVARIANCE THEOREM

#### Dimensionality Theorem

For a finite GROUP of  $h$  elements with an  $n_i$ th dimensional  $i$ th irreducible representation,

$$\sum_i n_i^2 = h.$$

#### Diminished Polyhedron

A UNIFORM POLYHEDRON with pieces removed.

#### Diminished Rhombicosidodecahedron

see JOHNSON SOLID

#### Dini Expansion

An expansion based on the ROOTS of

$$x^{-n}[xJ'_n(x) + HJ_n(x)] = 0,$$

where  $J_n(x)$  is a BESSEL FUNCTION OF THE FIRST KIND, is called a Dini expansion.

### Dinitz Problem

Given any assignment of  $n$ -element sets to the  $n^2$  locations of a square  $n \times n$  array, is it always possible to find a PARTIAL LATIN SQUARE? The fact that such a PARTIAL LATIN SQUARE can always be found for a  $2 \times 2$  array can be proven analytically, and techniques were developed which also proved the existence for  $4 \times 4$  and  $6 \times 6$  arrays. However, the general problem eluded solution until it was answered in the affirmative by Galvin in 1993 using results of Janssen (1993ab) and F. Maffray.

### Diocles's Cissoid

see CISSOID OF DIOCLES

### Diophantine Equation

An equation in which only INTEGER solutions are allowed. HILBERT'S 10TH PROBLEM asked if a technique for solving a general Diophantine existed. A general method exists for the solution of first degree Diophantine equations. However, the impossibility of obtaining a general solution was proven by Julia Robinson and Martin Davis in 1970, following proof of the result that the equation  $n = F_{2m}$  (where  $F_{2m}$  is a FIBONACCI NUMBER) is Diophantine by Yuri Matijasevič (Matijasevič 1970, Davis 1973, Davis and Hersch 1973, Matijasevič 1993).

No general method is known for quadratic or higher Diophantine equations. Jones and Matijasevič (1982) proved that no ALGORITHMS can exist to determine if an arbitrary Diophantine equation in nine variables has solutions. Ogilvy and Anderson (1988) give a number of Diophantine equations with known and unknown solutions.

D. Wilson has compiled a list of the smallest  $n$ th POWERS which are the sums of  $n$  distinct smaller  $n$ th POWERS. The first few are 3, 5, 6, 15, 12, 25, 40, ... (Sloane's A030052):

$$3^1 = 1^1 + 2^1$$

$$5^2 = 3^2 + 4^2$$

$$6^3 = 3^3 + 4^3 + 5^3$$

$$15^4 = 4^4 + 6^4 + 8^4 + 9^4 + 14^4$$

$$12^5 = 4^5 + 5^5 + 6^5 + 7^5 + 9^5 + 11^5$$

$$25^6 = 1^6 + 2^6 + 3^6 + 5^6 + 6^6 + 7^6 + 8^6 + 9^6 + 10^6 \\ + 12^6 + 13^6 + 15^6 + 16^6 + 17^6 + 18^6 + 23^6$$

$$40^7 = 1^7 + 3^7 + 5^7 + 9^7 + 12^7 + 14^7 + 16^7 + 17^7 \\ + 18^7 + 20^7 + 21^7 + 22^7 + 25^7 + 28^7 + 39^7$$

$$84^8 = 1^8 + 2^8 + 3^8 + 5^8 + 7^8 + 9^8 + 10^8 + 11^8 \\ + 12^8 + 13^8 + 14^8 + 15^8 + 16^8 + 17^8 + 18^8 \\ + 19^8 + 21^8 + 23^8 + 24^8 + 25^8 + 26^8 + 27^8 \\ + 29^8 + 32^8 + 33^8 + 35^8 + 37^8 + 38^8 + 39^8 \\ + 41^8 + 42^8 + 43^8 + 45^8 + 46^8 + 47^8 + 48^8 \\ + 49^8 + 51^8 + 52^8 + 53^8 + 57^8 + 58^8 + 59^8 \\ + 61^8 + 63^8 + 69^8 + 73^8$$

$$47^9 = 1^9 + 2^9 + 4^9 + 7^9 + 11^9 + 14^9 + 15^9 + 18^9 \\ + 26^9 + 27^9 + 30^9 + 31^9 + 32^9 + 33^9 \\ + 36^9 + 38^9 + 39^9 + 43^9$$

$$63^{10} = 1^{10} + 2^{10} + 4^{10} + 5^{10} + 6^{10} + 8^{10} + 12^{10} \\ + 15^{10} + 16^{10} + 17^{10} + 20^{10} + 21^{10} + 25^{10} \\ + 26^{10} + 27^{10} + 28^{10} + 30^{10} + 36^{10} + 37^{10} \\ + 38^{10} + 40^{10} + 51^{10} + 62^{10}.$$

### Diophantine Equation—5th Powers

The 2-1 fifth-order Diophantine equation

$$A^5 + B^5 = C^5 \quad (1)$$

is a special case of FERMAT'S LAST THEOREM with  $n = 5$ , and so has no solution. No solutions to the 2-2 equation

$$A^5 + B^5 = C^5 + D^5 \quad (2)$$

are known, despite the fact that sums up to  $1.02 \times 10^{26}$  have been checked (Guy 1994, p. 140), improving on the results on Lander *et al.* (1967), who checked up to  $2.8 \times 10^{14}$ . (In fact, no solutions are known for POWERS of 6 or 7 either.)

No solutions to the 3-1 equation

$$A^5 + B^5 + C^5 = D^5 \quad (3)$$

are known (Lander *et al.* 1967), nor are any 3-2 solutions up to  $8 \times 10^{12}$  (Lander *et al.* 1967).

Parametric solutions are known for the 3-3 (Guy 1994, pp. 140 and 142). Swinnerton-Dyer (1952) gave two parametric solutions to the 3-3 equation but, forty years later, W. Gosper discovered that the second scheme has an unfixable bug. The smallest primitive 3-3 solutions are

$$24^5 + 28^5 + 67^5 = 3^5 + 54^5 + 62^5 \quad (4)$$

$$18^5 + 44^5 + 66^5 = 13^5 + 51^5 + 64^5 \quad (5)$$

$$21^5 + 43^5 + 76^5 = 8^5 + 62^5 + 68^5 \quad (6)$$

$$56^5 + 67^5 + 83^5 = 53^5 + 72^5 + 81^5 \quad (7)$$

$$49^5 + 75^5 + 107^5 = 39^5 + 92^5 + 100^5 \quad (8)$$

(Moessner 1939, Moessner 1948, Lander *et al.* 1967).

For 4 fifth POWERS, we have the 4-1 equation

$$27^5 + 84^5 + 110^5 + 133^5 = 144^5 \quad (9)$$

(Lander and Parkin 1967, Lander *et al.* 1967), but it is not known if there is a parametric solution (Guy 1994, p. 140). Sastry's (1934) 5-1 solution gives some 4-2 solutions. The smallest primitive 4-2 solutions are

$$4^5 + 10^5 + 20^5 + 28^5 = 3^5 + 29^5 \quad (10)$$

$$5^5 + 13^5 + 25^5 + 37^5 = 12^5 + 38^5 \quad (11)$$

$$26^5 + 29^5 + 35^5 + 50^5 = 28^5 + 52^5 \quad (12)$$

$$5^5 + 25^5 + 62^5 + 63^5 = 61^5 + 64^5 \quad (13)$$

$$6^5 + 50^5 + 53^5 + 82^5 = 16^5 + 85^5 \quad (14)$$

$$56^5 + 63^5 + 72^5 + 86^5 = 31^5 + 96^5 \quad (15)$$

$$44^5 + 58^5 + 67^5 + 94^5 = 14^5 + 99^5 \quad (16)$$

$$11^5 + 13^5 + 37^5 + 99^5 = 63^5 + 97^5 \quad (17)$$

$$48^5 + 57^5 + 76^5 + 100^5 = 25^5 + 106^5 \quad (18)$$

$$58^5 + 76^5 + 79^5 + 102^5 = 54^5 + 111^5 \quad (19)$$

(Rao 1934, Moessner 1948, Lander *et al.* 1967).

A two-parameter solution to the 4-3 equation was given by Xeroudakes and Moessner (1958). Gloden (1949) also gave a parametric solution. The smallest solution is

$$1^5 + 8^5 + 14^5 + 27^5 = 3^5 + 22^5 + 25^5 \quad (20)$$

(Rao 1934, Lander *et al.* 1967). Several parametric solutions to the 4-4 equation were found by Xeroudakes and Moessner (1958). The smallest 4-4 solution is

$$5^5 + 6^5 + 6^5 + 8^5 = 4^5 + 7^5 + 7^5 + 7^5 \quad (21)$$

(Rao 1934, Lander *et al.* 1967). The first 4-4-4 equation is

$$3^5 + 48^5 + 52^5 + 61^5 = 13^5 + 36^5 + 51^5 + 64^5 \\ = 18^5 + 36^5 + 44^5 + 66^5 \quad (22)$$

(Lander *et al.* 1967).

Sastry (1934) found a 2-parameter solution for 5-1 equations

$$(75v^5 - u^5)^5 + (u^5 + 25v^5)^5 + (u^5 - 25v^5)^5 \\ + (10u^3v^2)^5 + (50uv^4)^5 = (u^5 + 75v^5)^5 \quad (23)$$

(quoted in Lander and Parkin 1967), and Lander and Parkin (1967) found the smallest numerical solutions. Lander *et al.* (1967) give a list of the smallest solutions, the first few being

$$19^5 + 43^5 + 46^5 + 47^5 + 67^5 = 72^5 \quad (24)$$

$$21^5 + 23^5 + 37^5 + 79^5 + 84^5 = 94^5 \quad (25)$$

$$7^5 + 43^5 + 57^5 + 80^5 + 100^5 = 107^5 \quad (26)$$

$$8^5 + 120^5 + 191^5 + 259^5 + 347^5 = 365^5 \quad (27)$$

$$79^5 + 202^5 + 258^5 + 261^5 + 395^5 = 415^5 \quad (28)$$

$$4^5 + 26^5 + 139^5 + 296^5 + 412^5 = 427^5 \quad (29)$$

$$31^5 + 105^5 + 139^5 + 314^5 + 416^5 = 435^5 \quad (30)$$

$$54^5 + 91^5 + 101^5 + 404^5 + 430^5 = 480^5 \quad (31)$$

$$19^5 + 201^5 + 347^5 + 388^5 + 448^5 = 503^5 \quad (32)$$

$$159^5 + 172^5 + 200^5 + 356^5 + 513^5 = 530^5 \quad (33)$$

$$218^5 + 276^5 + 385^5 + 409^5 + 495^5 = 553^5 \quad (34)$$

$$2^5 + 298^5 + 351^5 + 474^5 + 500^5 = 575^5 \quad (35)$$

(Lander and Parkin 1967, Lander *et al.* 1967).

The smallest primitive 5-2 solutions are

$$4^5 + 5^5 + 7^5 + 16^5 + 21^5 = 1^5 + 22^5 \quad (36)$$

$$9^5 + 11^5 + 14^5 + 18^5 + 30^5 = 23^5 + 29^5 \quad (37)$$

$$10^5 + 14^5 + 26^5 + 31^5 + 33^5 = 16^5 + 38^5 \quad (38)$$

$$4^5 + 22^5 + 29^5 + 35^5 + 36^5 = 24^5 + 42^5 \quad (39)$$

$$8^5 + 15^5 + 17^5 + 19^5 + 45^5 = 30^5 + 44^5 \quad (40)$$

$$5^5 + 6^5 + 26^5 + 27^5 + 44^5 = 36^5 + 42^5 \quad (41)$$

(Rao 1934, Lander *et al.* 1967).

The 6-1 equation has solutions

$$4^5 + 5^5 + 6^5 + 7^5 + 9^5 + 11^5 = 12^5 \quad (42)$$

$$5^5 + 10^5 + 11^5 + 16^5 + 19^5 + 29^5 = 30^5 \quad (43)$$

$$15^5 + 16^5 + 17^5 + 22^5 + 24^5 + 28^5 = 32^5 \quad (44)$$

$$13^5 + 18^5 + 23^5 + 31^5 + 36^5 + 66^5 = 67^5 \quad (45)$$

$$7^5 + 20^5 + 29^5 + 31^5 + 34^5 + 66^5 = 67^5 \quad (46)$$

$$22^5 + 35^5 + 48^5 + 58^5 + 61^5 + 64^5 = 78^5 \quad (47)$$

$$4^5 + 13^5 + 19^5 + 20^5 + 67^5 + 96^5 = 99^5 \quad (48)$$

$$6^5 + 17^5 + 60^5 + 64^5 + 73^5 + 89^5 = 99^5 \quad (49)$$

(Martin 1887, 1888, Lander and Parkin 1967, Lander *et al.* 1967).

The smallest 7-1 solution is

$$1^5 + 7^5 + 8^5 + 14^5 + 15^5 + 18^5 + 20^5 = 23^5 \quad (50)$$

(Lander *et al.* 1967).

# Diophantine Equation—6th Powers

The 2-1 equation

$$A^6 + B^6 = C^6 \quad (D1)$$

is a special case of FERMAT'S LAST THEOREM with  $n = 6$ , and so has no solution. Ekl (1996) has searched and found no solutions to the 2-2

$$A^6 + B^6 = C^6 + D^6 \quad (2)$$

with sums less than  $7.25 \times 10^{26}$ .

No solutions are known to the 3-1 or 3-2 equations. However, parametric solutions are known for the 3-3 equation

$$A^6 + B^6 + C^6 = D^6 + E^6 + F^6 \quad (3)$$

(Guy 1994, pp. 140 and 142). Known solutions are

$$3^6 + 19^6 + 22^6 = 10^6 + 15^6 + 23^6 \quad (4)$$

$$36^6 + 37^6 + 67^6 = 15^6 + 52^6 + 65^6 \quad (5)$$

$$33^6 + 47^6 + 74^6 = 23^6 + 54^6 + 73^6 \quad (6)$$

$$32^6 + 43^6 + 81^6 = 3^6 + 55^6 + 80^6 \quad (7)$$

$$37^6 + 50^6 + 81^6 = 11^6 + 65^6 + 78^6 \quad (8)$$

$$25^6 + 62^6 + 138^6 = 82^6 + 92^6 + 135^6 \quad (9)$$

$$51^6 + 113^6 + 136^6 = 40^6 + 125^6 + 129^6 \quad (10)$$

$$71^6 + 92^6 + 147^6 = 1^6 + 132^6 + 133^6 \quad (11)$$

$$111^6 + 121^6 + 230^6 = 26^6 + 169^6 + 225^6 \quad (12)$$

$$75^6 + 142^6 + 245^6 = 14^6 + 163^6 + 243^6 \quad (13)$$

(Rao 1934, Lander *et al.* 1967).

No solutions are known to the 4-1 or 4-2 equations. The smallest primitive 4-3 solutions are

$$41^6 + 58^6 + 73^6 = 15^6 + 32^6 + 65^6 + 70^6 \quad (14)$$

$$61^6 + 62^6 + 85^6 = 52^6 + 56^6 + 69^6 + 83^6 \quad (15)$$

$$61^6 + 74^6 + 85^6 = 26^6 + 56^6 + 71^6 + 87^6 \quad (16)$$

$$11^6 + 88^6 + 90^6 = 21^6 + 74^6 + 78^6 + 92^6 \quad (17)$$

$$26^6 + 83^6 + 95^6 = 23^6 + 24^6 + 28^6 + 101^6 \quad (18)$$

(Lander *et al.* 1967). Moessner (1947) gave three parametric solutions to the 4-4 equation. The smallest 4-4 solution is

$$2^6 + 2^6 + 9^6 + 9^6 = 3^6 + 5^6 + 6^6 + 10^6 \quad (19)$$

(Rao 1934, Lander *et al.* 1967). The smallest 4-4-4 solution is

$$\begin{aligned} 1^6 + 34^6 + 49^6 + 111^6 &= 7^6 + 43^6 + 69^6 + 110^6 \\ &= 18^6 + 25^6 + 77^6 + 109^6 \end{aligned} \quad (20)$$

(Lander *et al.* 1967).

No  $n$ -1 solutions are known for  $n \leq 6$  (Lander *et al.* 1967). No solution to the 5-1 equation is known (Guy 1994, p. 140) or the 5-2 equation.

No solutions are known to the 6-1 or 6-2 equations.

The smallest 7-1 solution is

$$74^6 + 234^6 + 402^6 + 474^6 + 702^6 + 894^6 + 1077^6 = 1141^6 \quad (21)$$

(Lander *et al.* 1967). The smallest 7-2 solution is

$$18^6 + 22^6 + 36^6 + 58^6 + 69^6 + 78^6 + 78^6 = 56^6 + 91^6 \quad (22)$$

(Lander *et al.* 1967).

The smallest primitive 8-1 solutions are

$$\begin{aligned} 8^6 + 12^6 + 30^6 + 78^6 + 102^6 \\ + 138^6 + 165^6 + 246^6 &= 251^6 \end{aligned} \quad (23)$$

$$\begin{aligned} 48^6 + 111^6 + 156^6 + 186^6 + 188^6 \\ + 228^6 + 240^6 + 426^6 &= 431^6 \end{aligned} \quad (24)$$

$$\begin{aligned} 93^6 + 93^6 + 195^6 + 197^6 + 303^6 \\ + 303^6 + 303^6 + 411^6 &= 440^6 \end{aligned} \quad (25)$$

$$\begin{aligned} 219^6 + 255^6 + 261^6 + 267^6 + 289^6 \\ + 351^6 + 351^6 + 351^6 &= 440^6 \end{aligned} \quad (26)$$

$$\begin{aligned} 12^6 + 66^6 + 138^6 + 174^6 + 212^6 \\ + 288^6 + 306^6 + 441^6 &= 455^6 \end{aligned} \quad (27)$$

$$\begin{aligned} 12^6 + 48^6 + 222^6 + 236^6 + 333^6 \\ + 384^6 + 390^6 + 426^6 &= 493^6 \end{aligned} \quad (28)$$

$$\begin{aligned} 66^6 + 78^6 + 144^6 + 228^6 + 256^6 \\ + 288^6 + 435^6 + 444^6 &= 499^6 \end{aligned} \quad (29)$$

$$\begin{aligned} 16^6 + 24^6 + 60^6 + 156^6 + 204^6 \\ + 276^6 + 330^6 + 492^6 &= 502^6 \end{aligned} \quad (30)$$

$$\begin{aligned} 61^6 + 96^6 + 156^6 + 228^6 + 276^6 \\ + 318^6 + 354^6 + 534^6 &= 547^6 \end{aligned} \quad (31)$$

$$\begin{aligned} 170^6 + 177^6 + 276^6 + 312^6 + 312^6 \\ + 408^6 + 450^6 + 498^6 &= 559^6 \end{aligned} \quad (32)$$

$$\begin{aligned} 60^6 + 102^6 + 126^6 + 261^6 + 270^6 \\ + 338^6 + 354^6 + 570^6 &= 581^6 \end{aligned} \quad (33)$$

$$\begin{aligned} 57^6 + 146^6 + 150^6 + 360^6 + 390^6 \\ + 402^6 + 444^6 + 528^6 &= 583^6 \end{aligned} \quad (34)$$

$$\begin{aligned} 33^6 + 72^6 + 122^6 + 192^6 + 204^6 \\ + 390^6 + 534^6 + 534^6 &= 607^6 \end{aligned} \quad (35)$$

$$\begin{aligned} 12^6 + 90^6 + 114^6 + 114^6 + 273^6 \\ + 306^6 + 492^6 + 592^6 &= 623^6 \end{aligned} \quad (36)$$

(Lander *et al.* 1967). The smallest 8-2 solution is

$$8^6 + 10^6 + 12^6 + 15^6 + 24^6 + 30^6 + 33^6 + 36^6 = 35^6 + 37^6 \quad (37)$$

(Lander *et al.* 1967).

The smallest 9-1 solution is

$$1^6 + 17^6 + 19^6 + 22^6 + 31^6 + 37^6 + 37^6 + 41^6 + 49^6 = 54^6 \quad (38)$$

(Lander *et al.* 1967). The smallest 9-2 solution is

$$1^6 + 5^6 + 5^6 + 7^6 + 13^6 + 13^6 + 13^6 + 17^6 + 19^6 = 6^6 + 21^6 \quad (39)$$

(Lander *et al.* 1967).

The smallest 10-1 solution is

$$2^6 + 4^6 + 7^6 + 14^6 + 16^6 + 26^6 + 26^6 + 30^6 + 32^6 + 32^6 = 39^6 \quad (40)$$

(Lander *et al.* 1967). The smallest 10-2 solution is

$$1^6 + 1^6 + 1^6 + 4^6 + 4^6 + 7^6 + 9^6 + 11^6 + 11^6 + 11^6 = 12^6 + 12^6 \quad (41)$$

(Lander *et al.* 1967).

The smallest 11-1 solution is

$$2^6 + 5^6 + 5^6 + 5^6 + 7^6 + 7^6 + 9^6 + 9^6 + 10^6 + 14^6 + 17^6 = 18^6 \quad (42)$$

(Lander *et al.* 1967).

There is also at least one 16-1 identity,

$$1^6 + 2^6 + 4^6 + 5^6 + 6^6 + 7^6 + 9^6 + 12^6 + 13^6 + 15^6 + 16^6 + 18^6 + 20^6 + 21^6 + 22^6 + 23^6 = 28^6 \quad (43)$$

(Martin 1893). Moessner (1959) gave solutions for 16-1, 18-1, 20-1, and 23-1.

#### Diophantine Equation—7th Powers

The 2-1 equation

$$A^7 + B^7 = C^7 \quad (1)$$

is a special case of FERMAT'S LAST THEOREM with  $n = 7$ , and so has no solution. No solutions to the 2-2 equation

$$A^7 + B^7 = C^7 + D^7 \quad (2)$$

are known

No solutions to the 3-1 or 3-2 equations are known, neither are solutions to the 3-3 equation

$$A^7 + B^7 + C^7 = D^7 + E^7 + F^7 \quad (3)$$

(Ekl 1996).

No 4-1, 4-2, or 4-3 solutions are known. Guy (1994, p. 140) asked if a 4-4 equation exists for 7th POWERS. An affirmative answer was provided by (Ekl 1996),

$$149^7 + 123^7 + 14^7 + 10^7 = 146^7 + 129^7 + 90^7 + 15^7 \quad (4)$$

$$194^7 + 150^7 + 105^7 + 23^7 = 192^7 + 152^7 + 132^7 + 38^7. \quad (5)$$

A 4-5 solution is known.

No 5-1, 5-2, or 5-3 solutions are known. Numerical solutions to the 5-4 equation are given by Gloden (1948). The smallest 5-4 solution is

$$3^7 + 11^7 + 26^7 + 29^7 + 52^7 = 12^7 + 16^7 + 43^7 + 50^7 \quad (6)$$

(Lander *et al.* 1967). Gloden (1949) gives parametric solutions to the 5-5 equation. The first few 5-5 solutions are

$$8^7 + 8^7 + 13^7 + 16^7 + 19^7 = 2^7 + 12^7 + 15^7 + 17^7 + 18^7 \quad (7)$$

$$4^7 + 8^7 + 14^7 + 16^7 + 23^7 = 7^7 + 7^7 + 9^7 + 20^7 + 22^7 \quad (8)$$

$$11^7 + 12^7 + 18^7 + 21^7 + 26^7 = 9^7 + 10^7 + 22^7 + 23^7 + 24^7 \quad (9)$$

$$6^7 + 12^7 + 20^7 + 22^7 + 27^7 = 10^7 + 13^7 + 13^7 + 25^7 + 26^7 \quad (10)$$

$$3^7 + 13^7 + 17^7 + 24^7 + 38^7 = 14^7 + 26^7 + 32^7 + 32^7 + 33^7 \quad (11)$$

(Lander *et al.* 1967).

No 6-1, 6-2, or 6-3 solutions are known. A parametric solution to the 6-6 equation was given by Sastry and Rai (1948). The smallest is

$$2^7 + 3^7 + 6^7 + 6^7 + 10^7 + 13^7 = 1^7 + 1^7 + 7^7 + 7^7 + 12^7 + 12^7 \quad (12)$$

(Lander *et al.* 1967).

There are no known solutions to the 7-1 equation (Guy 1994, p. 140). A 7<sup>2</sup>-2 solution is

$$\begin{aligned} 2^7 + 26^7 \\ = 4^7 + 8^7 + 13^7 + 14^7 + 14^7 + 16^7 + 18^7 + 22^7 + 23^7 + 23^7 \\ = 7^7 + 7^7 + 9^7 + 13^7 + 14^7 + 18^7 + 20^7 + 22^7 + 22^7 + 23^7 \end{aligned} \quad (13)$$

(Lander *et al.* 1967). The smallest 7-3 solution is

$$7^7 + 7^7 + 12^7 + 16^7 + 27^7 + 28^7 + 31^7 = 26^7 + 30^7 + 30^7 \quad (14)$$

(Lander *et al.* 1967).

The smallest 8-1 solution is

$$12^8 + 35^8 + 53^8 + 58^8 + 64^8 + 83^8 + 85^8 + 90^8 = 102^8 \quad (15)$$

(Lander *et al.* 1967). The smallest 8-2 solution is

$$5^7 + 6^7 + 7^7 + 15^7 + 15^7 + 20^7 + 28^7 + 31^7 = 10^7 + 33^7 \quad (16)$$

(Lander *et al.* 1967).

The smallest 9-1 solution is

$$6^7 + 14^7 + 20^7 + 22^7 + 27^7 + 33^7 + 41^7 + 50^7 + 59^7 = 62^7 \quad (17)$$

(Lander *et al.* 1967).

#### Diophantine Equation—8th Powers

The 2-1 equation

$$A^8 + B^8 = C^8 \quad (1)$$

is a special case of FERMAT'S LAST THEOREM with  $n = 8$ , and so has no solution. No 2-2 solutions are known.

No 3-1, 3-2, or 3-3 solutions are known.

No 4-1, 4-2, 4-3, or 4-4 solutions are known.

No 5-1, 5-2, 5-3, or 5-4 solutions are known, but Letac (1942) found a solution to the 5-5 equation. The smallest 5-5 solution is

$$1^8 + 10^8 + 11^8 + 20^8 + 43^8 = 5^8 + 28^8 + 32^8 + 35^8 + 41^8 \quad (2)$$

(Lander *et al.* 1967).

No 6-1, 6-2, 6-3, or 6-4 solutions are known. Moessner and Gloden (1944) found solutions to the 6-6 equation. The smallest 6-6 solution is

$$3^8 + 6^8 + 8^8 + 10^8 + 15^8 + 23^8 = 5^8 + 9^8 + 9^8 + 12^8 + 20^8 + 22^8 \quad (3)$$

(Lander *et al.* 1967).

No 7-1, 7-2, or 7-3 solutions are known. The smallest 7-4 solution is

$$7^8 + 9^8 + 16^8 + 22^8 + 22^8 + 28^8 + 34^8 = 6^8 + 11^8 + 20^8 + 35^8 \quad (4)$$

(Lander *et al.* 1967). Moessner and Gloden (1944) found solutions to the 7-6 equation. Parametric solutions to the 7-7 equation were given by Moessner (1947) and Gloden (1948). The smallest 7-7 solution is

$$1^8 + 3^8 + 5^8 + 6^8 + 6^8 + 8^8 + 13^8 = 4^8 + 7^8 + 9^8 + 9^8 + 10^8 + 11^8 + 12^8 \quad (5)$$

(Lander *et al.* 1967).

No 8-1 or 8-2 solutions are known. The smallest 8-3 solution is

$$6^8 + 12^8 + 16^8 + 16^8 + 38^8 + 38^8 + 40^8 + 47^8 = 8^8 + 17^8 + 50^8 \quad (6)$$

(Lander *et al.* 1967). Sastry (1934) used the smallest 17-1 solution to give a parametric 8-8 solution. The smallest 8-8 solution is

$$1^8 + 3^8 + 7^8 + 7^8 + 7^8 + 10^8 + 10^8 + 12^8 = 4^8 + 5^8 + 5^8 + 6^8 + 6^8 + 11^8 + 11^8 + 11^8 \quad (7)$$

(Lander *et al.* 1967).

No solutions to the 9-1 equation is known. The smallest 9-2 solution is

$$2^8 + 7^8 + 8^8 + 16^8 + 17^8 + 20^8 + 20^8 + 24^8 + 24^8 = 11^8 + 27^8 \quad (8)$$

(Lander *et al.* 1967). Letac (1942) found solutions to the 9-9 equation.

No solutions to the 10-1 equation are known.

The smallest 11-1 solution is

$$14^8 + 18^8 + 2 \cdot 44^8 + 66^8 + 70^8 + 92^8 + 93^8 + 96^8 + 106^8 + 112^8 = 125^8 \quad (9)$$

(Lander *et al.* 1967).

The smallest 12-1 solution is

$$2 \cdot 8^8 + 10^8 + 3 \cdot 24^8 + 26^8 + 30^8 + 34^8 + 44^8 + 52^8 + 63^8 = 65^8 \quad (10)$$

(Lander *et al.* 1967).

The general identity

$$(2^{8k+4} + 1)^8 = (2^{8k+4} - 1)^8 + (2^{7k+4})^8 + (2^{k+1})^8 + 7[(2^{5k+3})^8 + (2^{3k+2})^8] \quad (11)$$

gives a solution to the 17-1 equation (Lander *et al.* 1967).

## Diophantine Equation—9th Powers

The 2-1 equation

$$A^9 + B^9 = C^9 \quad (1)$$

is a special case of FERMAT'S LAST THEOREM with  $n = 9$ , and so has no solution. There is no known 2-2 solution.

There are no known 3-1, 3-2, or 3-3 solutions.

There are no known 4-1, 4-2, 4-3, or 4-4 solutions.

There are no known 5-1, 5-2, 5-3, 5-4, or 5-5 solutions.

There are no known 6-1, 6-2, 6-3, 6-4, or 6-5 solutions. The smallest 6-6 solution is

$$1^9 + 13^9 + 13^9 + 14^9 + 18^9 + 23^9 \\ = 5^9 + 9^9 + 10^9 + 15^9 + 21^9 + 22^9 \quad (2)$$

(Lander *et al.* 1967).

There are no known 7-1, 7-2, 7-3, 7-4, or 7-5 solutions.

There are no known 8-1, 8-2, 8-3, 8-4, or 8-5 solutions.

There are no known 9-1, 9-2, 9-3, 9-4, or 9-5 solutions.

There are no known 10-1, 10-2, or 10-3 solutions. The smallest 10-4 solution is

$$2^9 + 6^9 + 6^9 + 9^9 + 10^9 + 11^9 + 14^9 + 18^9 + 2 \cdot 19^9 \\ = 5^9 + 12^9 + 16^9 + 21^9 \quad (3)$$

(Lander *et al.* 1967). No 10-5 solution is known. Moessner (1947) gives a parametric solution to the 10-10 equation.

There are no known 11-1 or 11-2 solutions. The smallest 11-3 solution is

$$2^9 + 3^9 + 6^9 + 7^9 + 9^9 + 9^9 + 19^9 + 19^9 + 21^9 + 25^9 + 29^9 \\ = 13^9 + 16^9 + 30^9 \quad (4)$$

(Lander *et al.* 1967). The smallest 11-5 solution is

$$3^9 + 5^9 + 5^9 + 9^9 + 9^9 + 12^9 + 15^9 + 15^9 + 16^9 + 21^9 + 21^9 \\ = 7^9 + 8^9 + 14^9 + 20^9 + 22^9 \quad (5)$$

(Lander *et al.* 1967). Palamá (1953) gave a solution to the 11-11 equation.

There is no known 12-1 solution. The smallest 12-2 solution is

$$4 \cdot 2^9 + 2 \cdot 3^9 + 4^9 + 7^9 + 16^9 + 17^9 + 2 \cdot 19^9 \\ = 15^9 + 21^9 \quad (6)$$

(Lander *et al.* 1967).

There are no known 13-1 or 14-1 solutions. The smallest 15-1 solution is

$$2^9 + 2^9 + 4^9 + 6^9 + 6^9 + 7^9 + 9^9 + 9^9 + 10^9 + 15^9 \\ + 18^9 + 21^9 + 21^9 + 23^9 + 23^9 = 26^9 \quad (7)$$

(Lander *et al.* 1967).

## Diophantine Equation—10th Powers

The 2-1 equation

$$A^{10} + B^{10} = C^{10} \quad (1)$$

is a special case of FERMAT'S LAST THEOREM with  $n = 10$ , and so has no solution. The smallest values for which  $n-1$ ,  $n-2$ , etc., have solutions are 23, 19, 24, 23, 16, 27, and 7, corresponding to

$$5 \cdot 1^{10} + 2^{10} + 3^{10} + 6^{10} + 6 \cdot 7^{10} + 4 \cdot 9^{10} \\ + 10^{10} + 2 \cdot 12^{10} + 13^{10} + 14^{10} = 15^{10} \quad (2)$$

$$5 \cdot 2^{10} + 5^{10} + 6^{10} + 10^{10} + 6 \cdot 11^{10} \\ + 2 \cdot 12^{10} + 3 \cdot 15^{10} = 9^{10} + 17^{10} \quad (3)$$

$$1^{10} + 2^{10} + 3^{10} + 10 \cdot 4^{10} + 7^{10} + 7 \cdot 8^{10} \\ + 10^{10} + 12^{10} + 16^{10} = 11^{10} + 2 \cdot 15^{10} \quad (4)$$

$$5 \cdot 1^{10} + 2 \cdot 2^{10} + 3 \cdot 3^{10} + 4^{10} + 4 \cdot 6^{10} \\ + 3 \cdot 7^{10} + 8^{10} + 2 \cdot 10^{10} + 2 \cdot 14^{10} + 15^{10} = 3 \cdot 11^{10} + 16^{10} \quad (5)$$

$$4 \cdot 1^{10} + 2^{10} + 2 \cdot 4^{10} + 6^{10} + 2 \cdot 12^{10} \\ + 5 \cdot 13^{10} + 15^{10} = 2 \cdot 3^{10} + 8^{10} + 14^{10} + 16^{10} \quad (6)$$

$$1^{10} + 4 \cdot 3^{10} + 2 \cdot 4^{10} + 2 \cdot 5^{10} + 7 \cdot 6^{10} + 9 \cdot 7^{10} + 10^{10} + 13^{10} = 2 \cdot 2^{10} + 8^{10} + 11^{10} + 2 \cdot 12^{10} \quad (7)$$

$$1^{10} + 28^{10} + 31^{10} + 32^{10} + 55^{10} + 61^{10} + 68^{10} = 17^{10} + 20^{10} + 23^{10} + 44^{10} + 49^{10} + 64^{10} + 67^{10} \quad (8)$$

(Lander *et al.* 1967).

### Diophantine Equation—Cubic

The 2-1 equation

$$A^3 + B^3 = C^3 \quad (1)$$

is a case of FERMAT'S LAST THEOREM with  $n = 3$ . In fact, this particular case was known not to have any solutions long before the general validity of FERMAT'S LAST THEOREM was established. The 2-2 equation

$$A^3 + B^3 = C^3 + D^3 \quad (2)$$

has a known parametric solution (Dickson 1966, pp. 550–554; Guy 1994, p. 140), and 10 solutions with sum  $< 10^5$ ,

$$1729 = 1^3 + 12^3 = 9^3 + 10^3 \quad (3)$$

$$4104 = 2^3 + 16^3 = 9^3 + 15^3 \quad (4)$$

$$13832 = 2^3 + 24^3 = 18^3 + 20^3 \quad (5)$$

$$20683 = 10^3 + 27^3 = 19^3 + 24^3 \quad (6)$$

$$32832 = 4^3 + 32^3 = 18^3 + 30^3 \quad (7)$$

$$39312 = 2^3 + 34^3 = 15^3 + 33^3 \quad (8)$$

$$40033 = 9^3 + 34^3 = 16^3 + 33^3 \quad (9)$$

$$46683 = 3^3 + 36^3 = 16^3 + 33^3 \quad (10)$$

$$64232 = 17^3 + 39^3 = 26^3 + 36^3 \quad (11)$$

$$65728 = 12^3 + 40^3 = 31^3 + 33^3 \quad (12)$$

(Sloane's A001235; Moreau 1898). The first number (Madachy 1979, pp. 124 and 141) in this sequence, the so-called HARDY-RAMANUJAN NUMBER, is associated with a story told about Ramanujan by G. H. Hardy, but was known as early as 1657 (Berndt and Bhargava 1993). The smallest number representable in  $n$  ways as a sum of cubes is called the  $n$ th TAXICAB NUMBER.

Ramanujan gave a general solution to the 2-2 equation as

$$(\alpha + \lambda^2 \gamma)^3 + (\lambda \beta + \gamma)^3 = (\lambda \alpha + \gamma)^3 + (\beta + \lambda^2 \gamma)^3 \quad (13)$$

where

$$\alpha^2 + \alpha \beta + \beta^2 = 3 \lambda \gamma^2 \quad (14)$$

(Berndt 1994, p. 107). Another form due to Ramanujan is

$$(A^2 + 7AB - 9B^2)^3 + (2A^2 - 4AB + 12B^2)^3 = (2A^2 + 10B^2)^3 + (A^2 - 9AB - B^2)^3. \quad (15)$$

Hardy and Wright (1979, Theorem 412) prove that there are numbers that are expressible as the sum of two cubes in  $n$  ways for any  $n$  (Guy 1994, pp. 140–141). The proof is constructive, providing a method for computing such numbers: given RATIONALS NUMBERS  $r$  and  $s$ , compute

$$t = \frac{r(r^3 + 2s^3)}{r^3 - s^3} \quad (16)$$

$$u = \frac{s(2r^3 + s^3)}{r^3 - s^3} \quad (17)$$

$$v = \frac{t(t^3 - 2u^3)}{t^3 + u^3} \quad (18)$$

$$w = \frac{u(2t^3 - u^3)}{t^3 + u^3}. \quad (19)$$

Then

$$r^3 + s^3 = t^3 - u^3 = v^3 + w^3 \quad (20)$$

The DENOMINATORS can now be cleared to produce an integer solution. If  $r/s$  is picked to be large enough, the  $v$  and  $w$  will be POSITIVE. If  $r/s$  is still larger, the  $v/w$  will be large enough for  $v$  and  $w$  to be used as the inputs to produce a third pair, etc. However, the resulting integers may be quite large, even for  $n = 2$ . E.g., starting with  $3^3 + 1^3 = 28$ , the algorithm finds

$$28 = \left(\frac{28340511}{21446828}\right)^3 + \left(\frac{63284705}{21446828}\right)^3, \quad (21)$$

giving

$$28 \cdot 21446828^3 = (3 \cdot 21446828)^3 + 21446828^3 \quad (22)$$

$$= 28340511^3 + 63284705^3. \quad (23)$$

The numbers representable in three ways as a sum of two cubes (a 2-2-2 equation) are

$$87539319 = 167^3 + 436^3 = 228^3 + 423^3 = 255^3 + 414^3 \quad (24)$$

$$119824488 = 11^3 + 493^3 = 90^3 + 492^3 = 346^3 + 428^3 \quad (25)$$

$$143604279 = 111^3 + 522^3 = 359^3 + 460^3 = 408^3 + 423^3 \quad (26)$$

$$175959000 = 70^3 + 560^3 = 198^3 + 552^3 = 315^3 + 525^3 \quad (27)$$

$$327763000 = 300^3 + 670^3 = 339^3 + 661^3 = 510^3 + 580^3 \quad (28)$$

(Guy 1994, Sloane's A003825). Wilson (1997) found 32 numbers representable in four ways as the sum of two cubes (a 2-2-2-2 equation). The first is

$$6963472309248 = 2421^2 + 19083^2 = 5436^2 + 18948^2 \\ = 102020^3 + 18072^2 = 13322^3 + 15530^3. \quad (29)$$

The smallest known numbers so representable are 6963472309248, 12625136269928, 21131226514944, 26059452841000, ... (Sloane's A003826). Wilson also found six five-way sums,

$$48988659276962496 = 38787^3 + 365757^3 \\ = 107839^3 + 362753^3 \\ = 205292^3 + 342952^3 \\ = 221424^3 + 336588^3 \\ = 231518^3 + 331954^3 \quad (30)$$

$$490593422681271000 = 48369^3 + 788631^3 \\ = 233775^3 + 781785^3 \\ = 285120^3 + 776070^3 \\ = 543145^3 + 691295^3 \\ = 579240^3 + 666630^3 \quad (31)$$

$$6355491080314102272 = 103113^3 + 1852215^3 \\ = 580488^3 + 1833120^3 \\ = 788724^3 + 1803372^3 \\ = 1150792^3 + 1690544^3 \\ = 1462050^3 + 1478238^3 \quad (32)$$

$$27365551142421413376 = 167751^3 + 3013305^3 \\ = 265392^3 + 3012792^3 \\ = 944376^3 + 2982240^3 \\ = 1283148^3 + 2933844^3 \\ = 1872184^3 + 2750288^3 \quad (33)$$

$$1199962860219870469632 = 591543^3 + 10625865^3 \\ = 935856^3 + 10624056^3 \\ = 3330168^3 + 10516320^3 \\ = 6601912^3 + 9698384^3 \\ = 8387550^3 + 8480418^3 \quad (34)$$

$$111549833098123426841016 = 1074073^3 + 48137999^3 \\ = 8787870^3 + 48040356^3 \\ = 13950972^3 + 47744382^3 \\ = 24450192^3 + 45936462^3 \\ = 33784478^3 + 41791204^3, \quad (35)$$

and a single six-way sum

$$8230545258248091551205888 \\ = 11239317^3 + 201891435^3 \\ = 17781264^3 + 201857064^3 \\ = 63273192^3 + 199810080^3 \\ = 85970916^3 + 196567548^3 \\ = 125436328^3 + 184269296^3 \\ = 159363450^3 + 161127942^3. \quad (36)$$

The first rational solution to the 3-1 equation

$$A^3 + B^3 + C^3 = D^3 \quad (37)$$

was found by Euler and Vieta (Dickson 1966, pp. 550–554). Hardy and Wright (1979, pp. 199–201) give a solution which can be based on the identities

$$a^3(a^3 + b^3)^3 = b^3(a^3 + b^3)^3 + a^3(a^3 - 2b^3)^3 \\ + b^3(2a^3 - b^3)^3 \quad (38)$$

$$a^3(a^3 + 2b^3)^3 = a^3(a^3 - b^3)^3 + b^3(a^3 - b^3)^3 \\ + b^3(2a^3 + b^3)^3. \quad (39)$$

This is equivalent to the general 2-2 solution found by Ramanujan (Berndt 1994, pp. 54 and 107). The smallest integral solutions are

$$3^3 + 4^3 + 5^3 = 6^3 \quad (40)$$

$$1^3 + 6^3 + 8^3 = 9^3 \quad (41)$$

$$7^3 + 14^3 + 17^3 = 20^3 \quad (42)$$

$$11^3 + 15^3 + 27^3 = 29^3 \quad (43)$$

$$28^3 + 53^3 + 75^3 = 84^3 \quad (44)$$

$$26^3 + 55^3 + 78^3 = 87^3 \quad (45)$$

$$33^3 + 70^3 + 92^3 = 105^3 \quad (46)$$

(Beeler *et al.* 1972; Madachy 1979, pp. 124 and 141). Other general solutions have been found by Binet (1841) and Schwering (1902), although Ramanujan's formulation is the simplest. No general solution giving *all* POSITIVE integral solutions is known (Dickson 1966, pp. 550–561).

4-1 equations include

$$11^3 + 12^3 + 13^3 + 14^3 = 20^3 \quad (47)$$

$$5^3 + 7^3 + 9^3 + 10^3 = 13^3. \quad (48)$$

A solution to the 4-4 equation is

$$2^3 + 3^3 + 10^3 + 11^3 = 1^3 + 5^3 + 8^3 + 12^3 \quad (49)$$

(Madachy 1979, pp. 118 and 133).

5-1 equations

$$1^3 + 3^3 + 4^3 + 5^3 + 8^3 = 9^3 \quad (50)$$

$$3^3 + 4^3 + 5^3 + 8^3 + 10^3 = 12^3, \quad (51)$$

and a 6-1 equation is given by

$$1^3 + 5^3 + 6^3 + 7^3 + 8^3 + 10^3 = 13^3. \quad (52)$$

A 6-6 equation also exists:

$$1^3 + 2^3 + 4^3 + 8^3 + 9^3 + 12^3 = 3^3 + 5^3 + 6^3 + 7^3 + 10^3 + 11^3 \quad (53)$$

(Madachy 1979, p. 142).

Euler gave the general solution to

$$A^3 + B^3 = C^2 \quad (54)$$

as

$$A = 3n^3 + 6n^2 - n \quad (55)$$

$$B = -3n^3 + 6n^2 + n \quad (56)$$

$$C = 6n^2(3n^2 + 1). \quad (57)$$

#### Diophantine Equation—Linear

A linear Diophantine equation (in two variables) is an equation of the general form

$$ax + by = c, \quad (1)$$

where solutions are sought with  $a$ ,  $b$ , and  $c$  INTEGERS. Such equations can be solved completely, and the first known solution was constructed by Brahmagupta. Consider the equation

$$ax + by = 1. \quad (2)$$

Now use a variation of the EUCLIDEAN ALGORITHM, letting  $a = r_1$  and  $b = r_2$

$$r_1 = q_1 r_2 + r_3 \quad (3)$$

$$r_2 = q_2 r_3 + r_4 \quad (4)$$

$$r_{n-3} = q_{n-3} r_{n-2} + r_{n-1} \quad (5)$$

$$r_{n-2} = q_{n-2} r_{n-1} + 1. \quad (6)$$

Starting from the bottom gives

$$1 = r_{n-2} - q_{n-2} r_{n-1} \quad (7)$$

$$r_{n-1} = r_{n-3} - q_{n-3} r_{n-2}, \quad (8)$$

so

$$\begin{aligned} 1 &= r_{n-2} - q_{n-2}(r_{n-3} - q_{n-3} r_{n-2}) \\ &= -q_{n-2} r_{n-3} + (1 - q_{n-2} q_{n-3}) r_{n-2}. \end{aligned} \quad (9)$$

Continue this procedure all the way back to the top.

Take as an example the equation

$$1027x + 712y = 1. \quad (10)$$

Proceed as follows.

$$\begin{array}{ll} 1027 = 712 \cdot 1 + 315 & | \quad 1 = -165 \cdot 1027 + 238 \cdot 712 \uparrow \\ 712 = 315 \cdot 2 + 82 & | \quad 1 = 73 \cdot 712 - 165 \cdot 315 \uparrow \\ 315 = 82 \cdot 3 + 69 & | \quad 1 = -19 \cdot 315 + 73 \cdot 82 \uparrow \\ 82 = 69 \cdot 1 + 13 & | \quad 1 = 16 \cdot 82 - 19 \cdot 69 \uparrow \\ 69 = 13 \cdot 5 + 4 & | \quad 1 = -3 \cdot 69 + 16 \cdot 13 \uparrow \\ 13 = 4 \cdot 3 + 1 \downarrow & | \quad 1 = 1 \cdot 13 - 3 \cdot 4 \uparrow \\ & | \quad 1 = 0 \cdot 4 + 1 \cdot 1, \end{array}$$

The solution is therefore  $x = -165$ ,  $y = 238$ . The above procedure can be simplified by noting that the two left-most columns are offset by one entry and alternate signs, as they must since

$$1 = -A_{i+1} r_i + A_i r_{i+1} \quad (11)$$

$$r_{i+1} = r_{i-1} - r_i q_{i-1} \quad (12)$$

$$1 = A_i r_{i-1} - (A_i q_{i-1} + A_{i+1}), \quad (13)$$

so the COEFFICIENTS of  $r_{i-1}$  and  $r_{i+1}$  are the same and

$$A_{i-1} = -(A_i q_{i-1} + A_{i+1}). \quad (14)$$

Repeating the above example using this information therefore gives

$$\begin{array}{llll} 1027 = 712 \cdot 1 + 315 & | & (-) & 165 \cdot 1 + 73 = 238 \uparrow \\ 712 = 315 \cdot 2 + 82 & | & (+) & 73 \cdot 2 + 19 = 165 \uparrow \\ 315 = 82 \cdot 3 + 69 & | & (-) & 19 \cdot 3 + 16 = 73 \uparrow \\ 82 = 69 \cdot 1 + 13 & | & (+) & 16 \cdot 1 + 3 = 19 \uparrow \\ 69 = 13 \cdot 5 + 4 & | & (-) & 3 \cdot 5 + 1 = 16 \uparrow \\ 13 = 4 \cdot 3 + 1 \downarrow & | & (+) & 1 \cdot 3 + 0 = 3 \uparrow \\ & | & (-) & 0 \cdot 1 + 1 = 1 \uparrow \end{array}$$

and we recover the above solution.

Call the solutions to

$$ax + by = 1 \quad (15)$$

$x_0$  and  $y_0$ . If the signs in front of  $ax$  or  $by$  are NEGATIVE, then solve the above equation and take the signs of the solutions from the following table:

equation	$x$	$y$
$ax + by = 1$	$x_0$	$y_0$
$ax - by = 1$	$x_0$	$-y_0$
$-ax + by = 1$	$-x_0$	$y_0$
$-ax - by = 1$	$-x_0$	$-y_0$

In fact, the solution to the equation

$$ax - by = 1 \quad (16)$$

is equivalent to finding the CONTINUED FRACTION for  $a/b$ , with  $a$  and  $b$  RELATIVELY PRIME (Olds 1963). If there are  $n$  terms in the fraction, take the  $(n-1)$ th convergent  $p_{n-1}/q_{n-1}$ . But

$$p_n q_{n-1} - p_{n-1} q_n = (-1)^n, \quad (17)$$

so one solution is  $x_0 = (-1)^n q_{n-1}$ ,  $y_0 = (-1)^n p_{n-1}$ , with a general solution

$$x = x_0 + kb \quad (18)$$

$$y = y_0 + ka \quad (19)$$

with  $k$  an arbitrary INTEGER. The solution in terms of smallest POSITIVE INTEGERS is given by choosing an appropriate  $k$ .

Now consider the general first-order equation of the form

$$ax + by = c. \quad (20)$$

The GREATEST COMMON DIVISOR  $d \equiv \text{GCD}(a, b)$  can be divided through yielding

$$a'x + b'y = c', \quad (21)$$

where  $a' \equiv a/d$ ,  $b' \equiv b/d$ , and  $c' \equiv c/d$ . If  $d \nmid c$ , then  $c'$  is not an INTEGER and the equation cannot have a solution in INTEGERS. A necessary and sufficient condition for the general first-order equation to have solutions in INTEGERS is therefore that  $d \mid c$ . If this is the case, then solve

$$a'x + b'y = 1 \quad (22)$$

and multiply the solutions by  $c'$ , since

$$a'(c'x) + b'(c'y) = c'. \quad (23)$$

## Diophantine Equation— $n$ th Powers

The 2-1 equation

$$A^n + B^n = C^n \quad (1)$$

is a special case of FERMAT'S LAST THEOREM and so has no solutions for  $n \geq 3$ . Lander *et al.* (1967) give a table showing the smallest  $n$  for which a solution to

$$x_1^k + x_2^k + \dots + x_m^k = y_1^k + y_2^k + \dots + y_n^k,$$

with  $1 \leq m \leq n$  is known.

$m$	$k$									
	2	3	4	5	6	7	8	9	10	
1	2	3	3	4	7	8	11	15	23	
2	2	2	2	4	7	8	9	12	19	
3				3	3	7	8	11	24	
4						4	7	10	23	
5						5	5	11	16	
6								6	27	
7									7	

Take the results from the RAMANUJAN 6-10-8 IDENTITY that for  $ad = bc$ , with

$$\begin{aligned} F_{2m}(a, b, c, d) &= (a + b + c)^{2m} + (b + c + d)^{2m} \\ &- (c + d + a)^{2m} - (d + a + b)^{2m} + (a - d)^{2m} - (b - c)^{2m} \end{aligned} \quad (2)$$

and

$$\begin{aligned} f_{2m}(x, y) &= (1 + x + y)^{2m} + (x + y + xy)^{2m} \\ &- (y + xy + 1)^{2m} - (xy + 1 + x)^{2m} + (1 - xy)^{2m} - (x - y)^{2m}, \end{aligned} \quad (3)$$

then

$$F_{2m}(a, b, c, d) = a^{2m} f_{2m}(x, y). \quad (4)$$

Using

$$f_2(x, y) = 0 \quad (5)$$

$$f_4(x, y) = 0 \quad (6)$$

now gives

$$\begin{aligned} (a + b + c)^n + (b + c + d)^n + (a - d)^n \\ = (c + d + a)^n + (d + a + b)^n + (b - c)^n \end{aligned} \quad (7)$$

for  $n = 2$  or  $4$ .

### Diophantine Equation—Quadratic

An equation of the form

$$x^2 - Dy^2 = 1, \quad (1)$$

where  $D$  is an INTEGER is called a PELL EQUATION. Pell equations, as well as the analogous equation with a minus sign on the right, can be solved by finding the CONTINUED FRACTION for  $\sqrt{D}$ . (The trivial solution  $x = 1, y = 0$  is ignored in all subsequent discussion.) Let  $p_n/q_n$  denote the  $n$ th CONVERGENT  $[a_1, a_2, \dots, a_n]$ , then we are looking for a convergent which obeys the identity

$$p_n^2 - Dq_n^2 = (-1)^n, \quad (2)$$

which turns out to always be possible since the CONTINUED FRACTION of a QUADRATIC SURD always becomes periodic at some term  $a_{r+1}$ , where  $a_{r+1} = 2a_1$ , i.e.,

$$\sqrt{D} = [a_1, \overline{a_2, \dots, a_r, 2a_1}]. \quad (3)$$

Writing  $n = rk$  gives

$$p_{rk}^2 - Dq_{rk}^2 = (-1)^{rk}, \quad (4)$$

for  $k$  a POSITIVE INTEGER. If  $r$  is ODD, solutions to

$$x^2 - Dy^2 = \pm 1 \quad (5)$$

can be obtained if  $k$  is chosen to be EVEN or ODD, but if  $r$  is EVEN, there are no values of  $k$  which can make the exponent ODD.

If  $r$  is EVEN, then  $(-1)^r$  is POSITIVE and the solution in terms of smallest INTEGERS is  $x = p_r$  and  $y = q_r$ , where  $p_r/q_r$  is the  $r$ th CONVERGENT. If  $r$  is ODD, then  $(-1)^r$  is NEGATIVE, but we can take  $k = 2$  in this case, to obtain

$$p_{2r}^2 - Dq_{2r}^2 = 1, \quad (6)$$

so the solution in smallest INTEGERS is  $x = p_{2r}, y = q_{2r}$ . Summarizing,

$$(x, y) = \begin{cases} (p_r, q_r) & \text{for } r \text{ even} \\ (p_{2r}, q_{2r}) & \text{for } r \text{ odd.} \end{cases} \quad (7)$$

The more complicated equation

$$x^2 - Dy^2 = \pm c \quad (8)$$

can also be solved for certain values of  $c$  and  $D$ , but the procedure is more complicated (Chrystal 1961). However, if a single solution to the above equation is known, other solutions can be found. Let  $p$  and  $q$  be solutions to (8), and  $r$  and  $s$  solutions to the "unit" form". Then

$$(p^2 - Dq^2)(r^2 - Ds^2) = \pm c \quad (9)$$

$$(pr \pm Dqs)^2 - D(ps \pm qr)^2 = \pm c. \quad (10)$$

Call a Diophantine equation consisting of finding  $m$  POWERS equal to a sum of  $n$  equal POWERS an " $m - n$  equation." The 2-1 equation

$$A^2 = B^2 + C^2, \quad (11)$$

which corresponds to finding a PYTHAGOREAN TRIPLE  $(A, B, C)$  has a well-known general solution (Dickson 1966, pp. 165-170). To solve the equation, note that every PRIME of the form  $4x + 1$  can be expressed as the sum of two RELATIVELY PRIME squares in exactly one way. To find in how many ways a general number  $m$  can be expressed as a sum of two squares, factor it as follows

$$m = 2^{a_0} p_1^{2a_1} \dots p_n^{2a_n} q_1^{b_1} \dots q_r^{b_r}, \quad (12)$$

where the  $p$ s are primes of the form  $4x - 1$  and the  $q$ s are primes of the form  $x + 1$ . If the  $a$ s are integral, then define

$$B \equiv (2b_1 + 1)(2b_2 + 1) \dots (2b_r + 1) - 1. \quad (13)$$

Then  $m$  is a sum of two *unequal* squares in

$$N(m) = \begin{cases} 0 & \text{for any } a_i \text{ half-integral} \\ \frac{1}{2}(b_1 + 1)(b_2 + 1) \dots (b_r + 1) & \text{for all } a_i \text{ integral, } B \text{ odd} \\ \frac{1}{2}(b_1 + 1)(b_2 + 1) \dots (b_r + 1) - \frac{1}{2} & \text{for all } a_i \text{ integral, } B \text{ even.} \end{cases} \quad (14)$$

If zero is counted as a square, both POSITIVE and NEGATIVE numbers are included, and the order of the two squares is distinguished, Jacobi showed that the number of ways a number can be written as the sum of two squares is four times the excess of the number of DIVISORS of the form  $4x + 1$  over the number of DIVISORS of the form  $4x - 1$ .

A set of INTEGERS satisfying the 3-1 equation

$$A^2 + B^2 + C^2 = D^2 \quad (15)$$

is called a PYTHAGOREAN QUADRUPLE. Parametric solutions to the 2-2 equation

$$A^2 + B^2 = C^2 + D^2 \quad (16)$$

are known (Dickson 1966; Guy 1994, p. 140).

Solutions to an equation of the form

$$(A^2 + B^2)(C^2 + D^2) = E^2 + F^2 \quad (17)$$

are given by the FIBONACCI IDENTITY

$$(a^2 + b^2)(c^2 + d^2) = (ac \pm bd)^2 + (bc \mp ad)^2 \equiv e^2 + f^2. \quad (18)$$

Another similar identity is the EULER FOUR-SQUARE IDENTITY

$$(a_1^2 + a_2^2)(b_1^2 + b_2^2)(c_1^2 + c_2^2)(d_1^2 + d_2^2) = e_1^2 + e_2^2 + e_3^2 + e_4^2 \quad (19)$$

$$\begin{aligned} &(a_1^2 + a_2^2 + a_3^2 + a_4^2)(b_1^2 + b_2^2 + b_3^2 + b_4^2) \\ &= (a_1b_1 - a_2b_2 - a_3b_3 - a_4b_4)^2 \\ &\quad + (a_1b_2 + a_2b_1 + a_3b_4 - a_4b_3)^2 \\ &\quad + (a_1b_3 - a_2b_4 + a_3b_1 + a_4b_2)^2 \\ &\quad + (a_1b_4 + a_2b_3 - a_3b_2 + a_4b_1)^2. \end{aligned} \quad (20)$$

Degen's eight-square identity holds for eight squares, but no other number, as proved by Cayley. The two-square identity underlies much of TRIGONOMETRY, the four-square identity some of QUATERNIONS, and the eight-square identity, the CAYLEY ALGEBRA (a noncommutative nonassociative algebra; Bell 1945).

RAMANUJAN'S SQUARE EQUATION

$$2^n - 7 = x^2 \quad (21)$$

has been proved to have only solutions  $n = 3, 4, 5, 7$ , and 15 (Beeler *et al.* 1972, Item 31).

#### Diophantine Equation—Quartic

Call an equation involving quartics  $m$ - $n$  if a sum of  $m$  quartics is equal to a sum of  $n$  fourth POWERS. The 2-1 equation

$$A^4 + B^4 = C^4 \quad (1)$$

is a case of FERMAT'S LAST THEOREM with  $n = 4$  and therefore has no solutions. In fact, the equations

$$A^4 \pm B^4 = C^2 \quad (2)$$

also have no solutions in INTEGERS.

Parametric solutions to the 2-2 equation

$$A^4 + B^4 = C^4 + D^4 \quad (3)$$

are known (Euler 1802; Gérardin 1917; Guy 1994, pp. 140–141). A few specific solutions are

$$59^4 + 158^4 = 133^4 + 134^4 = 635,318,657 \quad (4)$$

$$7^4 + 239^4 = 157^4 + 227^4 = 3,262,811,042 \quad (5)$$

$$193^4 + 292^4 = 256^4 + 257^4 = 8,657,437,697 \quad (6)$$

$$298^4 + 497^4 = 271^4 + 502^4 = 68,899,596,497 \quad (7)$$

$$514^4 + 359^4 = 103^4 + 542^4 = 86,409,838,577 \quad (8)$$

$$222^4 + 631^4 = 503^4 + 558^4 = 160,961,094,577 \quad (9)$$

$$21^4 + 717^4 = 471^4 + 681^4 = 264,287,694,402 \quad (10)$$

$$76^4 + 1203^4 = 653^4 + 1176^4 = 2,094,447,251,857 \quad (11)$$

$$997^4 + 1342^4 = 878^4 + 1381^4 = 4,231,525,221,377 \quad (12)$$

$$27^4 + 2379^4 = 577^4 + 728^4 = 32,031,536,780,322 \quad (13)$$

(Sloane's A001235; Richmond 1920, Leech 1957), the smallest of which is due to Euler. Lander *et al.* (1967) give a list of 25 primitive 2-2 solutions. General (but incomplete) solutions are given by

$$x = a + b \quad (14)$$

$$y = c - d \quad (15)$$

$$u = a - b \quad (16)$$

$$v = c + d, \quad (17)$$

where

$$a = n(m^2 + n^2)(-m^4 + 18m^2n^2 - n^4) \quad (18)$$

$$b = 2m(m^6 + 10m^4n^2 + m^2n^4 + 4n^6) \quad (19)$$

$$c = 2n(4m^6 + m^4n^2 + 10m^2n^4 + n^6) \quad (20)$$

$$d = m(m^2 + n^2)(-m^4 + 18m^2n^2 - n^4) \quad (21)$$

(Hardy and Wright 1979).

In 1772, Euler proposed that the 3-1 equation

$$A^4 + B^4 + C^4 = D^4 \quad (22)$$

had no solutions in INTEGERS (Lander *et al.* 1967). This assertion is known as the EULER QUARTIC CONJECTURE. Ward (1948) showed there were no solutions for  $D \leq 10,000$ , which was subsequently improved to  $D \leq 220,000$  by Lander *et al.* (1967). However, the EULER QUARTIC CONJECTURE was disproved in 1987 by Noam D. Elkies, who, using a geometric construction, found

$$2,682,440^4 + 15,365,639^4 + 18,796,760^4 = 20,615,673^4 \quad (23)$$

and showed that infinitely many solutions existed (Guy 1994, p. 140). In 1988, Roger Frye found

$$95,800^4 + 217,519^4 + 414,560^4 = 422,481^4 \quad (24)$$

and proved that there are no solutions in smaller INTEGERS (Guy 1994, p. 140). Another solution was found by Allan MacLeod in 1997,

$$638,523,249^4 = 630,662,624^4 + 275,156,240^4 + 219,076,465^4. \quad (25)$$

It is not known if there is a parametric solution.

In contrast, there are many solutions to the 3-1 equation

$$A^4 + B^4 + C^4 = 2D^4 \quad (26)$$

(see below).

Parametric solutions to the 3-2 equation

$$A^4 + B^4 = C^4 + D^4 + E^4 \quad (27)$$

are known (Gérardin 1910, Ferrari 1913). The smallest 3-2 solution is

$$3^4 + 5^4 + 8^4 = 7^4 + 7^4 \quad (28)$$

(Lander *et al.* 1967).

Ramanujan gave the 3-3 equations

$$2^4 + 4^4 + 7^4 = 3^4 + 6^4 + 6^4 \quad (29)$$

$$3^4 + 7^4 + 8^4 = 1^4 + 2^4 + 9^4 \quad (30)$$

$$6^4 + 9^4 + 12^4 = 2^4 + 2^4 + 13^4 \quad (31)$$

(Berndt 1994, p. 101). Similar examples can be found in Martin (1896). Parametric solutions were given by Gérardin (1911).

Ramanujan also gave the general expression

$$3^4 + (2x^4 - 1)^4 + (4x^5 + x)^4 = (4x^4 + 1)^4 + (6x^4 - 3)^4 + (4x^5 - 5x)^4 \quad (32)$$

(Berndt 1994, p. 106). Dickson (1966, pp. 653–655) cites several FORMULAS giving solutions to the 3-3 equation, and Haldeman (1904) gives a general FORMULA.

The 4-1 equation

$$A^4 + B^4 + C^4 + D^4 = E^4 \quad (33)$$

has solutions

$$30^4 + 120^4 + 272^4 + 315^4 = 353^4 \quad (34)$$

$$240^4 + 340^4 + 430^4 + 599^4 = 651^4 \quad (35)$$

$$435^4 + 710^4 + 1384^4 + 2420^4 = 2487^4 \quad (36)$$

$$1130^4 + 1190^4 + 1432^4 + 2365^4 = 2501^4 \quad (37)$$

$$850^4 + 1010^4 + 1546^4 + 2745^4 = 2829^4 \quad (38)$$

$$2270^4 + 2345^4 + 2460^4 + 3152^4 = 3723^4 \quad (39)$$

$$350^4 + 1652^4 + 3230^4 + 3395^4 = 3973^4 \quad (40)$$

$$205^4 + 1060^4 + 2650^4 + 4094^4 = 4267^4 \quad (41)$$

$$1394^4 + 1750^4 + 3545^4 + 3670^4 = 4333^4 \quad (42)$$

$$699^4 + 700^4 + 2840^4 + 4250^4 = 4449^4 \quad (43)$$

$$380^4 + 1660^4 + 1880^4 + 4907^4 = 4949^4 \quad (44)$$

$$1000^4 + 1120^4 + 3233^4 + 5080^4 = 5281^4 \quad (45)$$

$$410^4 + 1412^4 + 3910^4 + 5055^4 = 5463^4 \quad (46)$$

$$955^4 + 1770^4 + 2634^4 + 5400^4 = 5491^4 \quad (47)$$

$$30^4 + 1680^4 + 3043^4 + 5400^4 = 5543^4 \quad (48)$$

$$1354^4 + 1810^4 + 4355^4 + 5150^4 = 5729^4 \quad (49)$$

$$542^4 + 2770^4 + 4280^4 + 5695^4 = 6167^4 \quad (50)$$

$$50^4 + 885^4 + 5000^4 + 5984^4 = 6609^4 \quad (51)$$

$$1490^4 + 3468^4 + 4790^4 + 6185^4 = 6801^4 \quad (52)$$

$$1390^4 + 2850^4 + 5365^4 + 6368^4 = 7101^4 \quad (53)$$

$$160^4 + 1345^4 + 2790^4 + 7166^4 = 7209^4 \quad (54)$$

$$800^4 + 3052^4 + 5440^4 + 6635^4 = 7339^4 \quad (55)$$

$$2230^4 + 3196^4 + 5620^4 + 6995^4 = 7703^4 \quad (56)$$

(Norrie 1911, Patterson 1942, Leech 1958, Brudno 1964, Lander *et al.* 1967), but it is not known if there is a parametric solution (Guy 1994, p. 139).

Ramanujan gave the 4-2 equation

$$3^4 + 9^4 = 5^4 + 5^4 + 6^4 + 6^4, \quad (57)$$

and the 4-3 identities

$$2^4 + 2^4 + 7^4 = 4^4 + 4^4 + 5^4 + 6^4 \quad (58)$$

$$3^4 + 9^4 + 14^4 = 7^4 + 8^4 + 10^4 + 13^4 \quad (59)$$

$$7^4 + 10^4 + 13^4 = 5^4 + 5^4 + 6^4 + 14^4 \quad (60)$$

(Berndt 1994, p. 101). Haldeman (1904) gives general FORMULAS for 4-2 and 4-3 equations.

There are an infinite number of solutions to the 5-1 equation

$$A^4 + B^4 + C^4 + D^4 + E^4 = F^4. \quad (61)$$

Some of the smallest are

$$2^4 + 2^4 + 3^4 + 4^2 + 4^2 = 5^4 \quad (62)$$

$$4^4 + 6^4 + 8^4 + 9^4 + 14^4 = 15^4 \quad (63)$$

$$4^4 + 21^4 + 22^4 + 26^4 + 28^4 = 35^4 \quad (64)$$

$$1^4 + 2^4 + 12^4 + 24^4 + 44^4 = 45^4 \quad (65)$$

$$1^4 + 8^4 + 12^4 + 32^4 + 64^4 = 65^4 \quad (66)$$

$$2^4 + 39^4 + 44^4 + 46^4 + 52^4 = 65^4 \quad (67)$$

$$22^4 + 52^4 + 57^4 + 74^4 + 76^4 = 95^4 \quad (68)$$

$$22^4 + 28^4 + 63^4 + 72^4 + 94^4 = 105^4 \quad (69)$$

(Berndt 1994). Berndt and Bhargava (1993) and Berndt (1994, pp. 94–96) give Ramanujan's solutions for arbitrary  $s, t, m$ , and  $n$ ,

$$\begin{aligned} (8s^2 + 40st - 24t^2)^4 + (6s^2 - 44st - 18t^2)^4 \\ + (14s^2 - 4st - 42t^2)^4 + (9s^2 + 27t^2)^4 + (4s^2 + 12t^2)^4 \\ = (15s^2 + 45t^2)^4, \quad (70) \end{aligned}$$

and

$$\begin{aligned} (4m^2 - 12n^2)^4 + (3m^2 + 9n^2)^4 + (2m^2 - 12mn - 6n^2)^4 \\ + (4m^2 + 12n^2)^4 + (2m^2 + 12mn - 6n^2)^4 = (5m^2 + 15n^2)^4. \quad (71) \end{aligned}$$

These are also given by Dickson (1966, p. 649), and two general FORMULAS are given by Beiler (1966, p. 290). Other solutions are given by Fauquembergue (1898), Haldeman (1904), and Martin (1910).

Ramanujan gave

$$2(ab + ac + bc)^2 = a^4 + b^4 + c^4 \quad (72)$$

$$2(ab + ac + bc)^4 = a^4(b - c)^4 + b^4(c - a)^4 + c^4(a - b)^4 \quad (73)$$

$$\begin{aligned} 2(ab + ac + bc)^6 = (a^2b + b^2c + c^2a)^4 \\ + (ab^2 + bc^2 + ca^2)^4 + (3abc)^4 \quad (74) \end{aligned}$$

$$\begin{aligned} 2(ab + ac + bc)^8 = (a^3 + 2abc)^4(b - c)^4 \\ + (b^3 + 2abc)^4(c - a)^4 + (c^3 + 2abc)^4(a - b)^4, \quad (75) \end{aligned}$$

where

$$a + b + c = 0 \quad (76)$$

(Berndt 1994, pp. 96–97). FORMULA (73) is equivalent to FERRARI'S IDENTITY

$$\begin{aligned} (a^2 + 2ac - 2bc - b^2)^4 + (b^2 - 2ab - 2ac - c^2)^4 \\ + (c^2 + 2ab + 2bc - a^2)^4 = 2(a^2 + b^2 + c^2 - ab + ac + bc)^4. \quad (77) \end{aligned}$$

BHARGAVA'S THEOREM is a general identity which gives the above equations as a special case, and may have been the route by which Ramanujan proceeded. Another identity due to Ramanujan is

$$\begin{aligned} (a + b + c)^4 + (b + c + d)^4 + (a - d)^4 \\ = (c + d + a)^4 + (d + a + b)^4 + (b - c)^4, \quad (78) \end{aligned}$$

where  $a/b = c/d$ , and 4 may also be replaced by 2 (Ramanujan 1957, Hirschhorn 1998).

V. Kyratatas noticed that  $a = 3, b = 7, c = 20, d = 25, e = 38$ , and  $f = 39$  satisfy

$$\frac{a^4 + b^4 + c^4}{d^4 + e^4 + f^4} = \frac{a + b + c}{d + e + f} \quad (79)$$

and asks if there are any other distinct integer solutions.

The first few numbers  $n$  which are a sum of two or more fourth POWERS ( $m - 1$  equations) are 353, 651, 2487, 2501, 2829, ... (Sloane's A003294). The only number of the form

$$4x^4 + y^4 \quad (80)$$

which is PRIME is 5 (Baudran 1885, Le Lionnais 1983).

## Diophantine Quadruple

see DIOPHANTINE SET

## Diophantine Set

A set  $S$  of POSITIVE integers is said to be Diophantine IFF there exists a POLYNOMIAL  $Q$  with integral coefficients in  $m \geq 1$  indeterminates such that

$$S = \{Q(x_1, \dots, x_m) \geq 1 : x_1 \geq 1, \dots, x_m \geq 1\}.$$

It has been proved that the set of PRIME numbers is a Diophantine set.

## Diophantus Property

A set of POSITIVE INTEGERS  $S = \{a_1, \dots, a_m\}$  satisfies the Diophantus property  $D(n)$  of order  $n$  if, for all  $i, j = 1, \dots, m$  with  $i \neq j$ ,

$$a_i a_j + n = b_{ij}^2, \quad (1)$$

where  $n$  and  $b_{ij}$  are INTEGERS. The set  $S$  is called a Diophantine  $n$ -tuple. Fermat found the first  $D(1)$  quadruple:  $\{1, 3, 8, 120\}$ . General  $D(1)$  quadruples are

$$\{F_{2n}, F_{2n+2}, F_{2n+4}, 4F_{2n+1}F_{2n+2}F_{2n+3}\} \quad (2)$$

where  $F_n$  are FIBONACCI NUMBERS, and

$$\{n, n+2, 4n+4, 4(n+1)(2n+1)(2n+3)\}. \quad (3)$$

The quadruplet

$$\{2F_{n-1}, 2F_{n+1}, 2F_n^3 F_{n+1} F_{n+2}, 2F_{n+1} F_{n+2} F_{n+3} (2F_{n+1}^2 - F_n^2)\} \quad (4)$$

is  $D(F_n^2)$  (Dujella 1996). Dujella (1993) showed there exist no Diophantine quadruples  $D(4k+2)$ .

## Diophantus' Riddle

"Diophantus' youth lasts  $1/6$  of his life. He grew a beard after  $1/12$  more of his life. After  $1/7$  more of his life, Diophantus married. Five years later, he had a son. The son lived exactly half as long as his father, and Diophantus died just four years after his son's death. All of this totals the years Diophantus lived."

Let  $D$  be the number of years Diophantus lived, and let  $S$  be the number of years his son lived. Then the above word problem gives the two equations

$$\begin{aligned} D &= \left(\frac{1}{6} + \frac{1}{12} + \frac{1}{7}\right)D + 5 + S + 4 \\ S &= \frac{1}{2}D. \end{aligned}$$

Solving this simultaneously gives  $S = 42$  as the age of the son and  $D = 84$  as the age of Diophantus.

### Dirac Delta Function

see DELTA FUNCTION

### Dirac Matrices

Define the  $4 \times 4$  matrices

$$\sigma_i = \mathbf{I} \otimes \sigma_i, \text{ Pauli} \quad (1)$$

$$\rho_i = \sigma_i, \text{ Pauli} \otimes \mathbf{I}, \quad (2)$$

where  $\sigma_i, \text{ Pauli}$  are the PAULI MATRICES,  $\mathbf{I}$  is the IDENTITY MATRIX,  $i = 1, 2, 3$ , and  $A \otimes B$  is the matrix DIRECT PRODUCT. Explicitly,

$$\mathbf{I} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (3)$$

$$\sigma_1 = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \quad (4)$$

$$\sigma_2 = \begin{bmatrix} 0 & -i & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & -i \\ 0 & 0 & i & 0 \end{bmatrix} \quad (5)$$

$$\sigma_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (6)$$

$$\rho_1 = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \quad (7)$$

$$\rho_2 = \begin{bmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & -i \\ i & 0 & 0 & 0 \\ 0 & i & 0 & 0 \end{bmatrix} \quad (8)$$

$$\rho_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (9)$$

These matrices satisfy the anticommutation identities

$$\sigma_i \sigma_j + \sigma_j \sigma_i = 2\delta_{ij} \mathbf{I} \quad (10)$$

$$\rho_i \rho_j + \rho_j \rho_i = 2\delta_{ij} \mathbf{I}, \quad (11)$$

where  $\delta_{ij}$  is the KRONECKER DELTA, the commutation identity

$$[\sigma_i, \rho_j] = \sigma_i \rho_j - \rho_j \sigma_i = 0, \quad (12)$$

and are cyclic under permutations of indices

$$\sigma_i \sigma_j = i \sigma_k \quad (13)$$

$$\rho_i \rho_j = i \rho_k. \quad (14)$$

A total of 16 Dirac matrices can be defined via

$$\mathbf{E}_{ij} = \rho_i \sigma_j \quad (15)$$

for  $i, j = 0, 1, 2, 3$  and where  $\sigma_0 = \rho_0 \equiv \mathbf{I}$ . These matrix satisfy

1.  $|\mathbf{E}_{ij}| = 1$ , where  $|\mathbf{A}|$  is the DETERMINANT,
2.  $\mathbf{E}_{ij}^2 = \mathbf{I}$ ,
3.  $\mathbf{E}_{ij} = \mathbf{E}_{ij}^\dagger$ , making them Hermitian, and therefore unitary,
4.  $\text{tr}(\mathbf{E}_{ij}) = 0$ , except  $\text{tr}(\mathbf{E}_{00}) = 4$ ,
5. Any two  $\mathbf{E}_{ij}$  multiplied together yield a Dirac matrix to within a multiplicative factor of  $-i$  or  $\pm i$ ,
6. The  $\mathbf{E}_{ij}$  are linearly independent,
7. The  $\mathbf{E}_{ij}$  form a complete set, i.e., any  $4 \times 4$  constant matrix may be written as

$$\mathbf{A} = \sum_{i,j=0}^3 c_{ij} \mathbf{E}_{ij}, \quad (16)$$

where the  $c_{ij}$  are real or complex and are given by

$$c_{mn} = \frac{1}{4} \text{tr}(\mathbf{A} \mathbf{E}_{mn}) \quad (17)$$

(Arfken 1985).

Dirac's original matrices were written  $\alpha_i$  and were defined by

$$\alpha_i = \mathbf{E}_{1i} = \rho_1 \sigma_i \quad (18)$$

$$\alpha_4 = \mathbf{E}_{30} = \rho_3, \quad (19)$$

for  $i = 1, 2, 3$ , giving

$$\alpha_1 = \mathbf{E}_{1i} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix} \quad (20)$$

$$\alpha_2 = \mathbf{E}_{2i} = \begin{bmatrix} 0 & 0 & 0 & -i \\ 0 & 0 & i & 0 \\ 0 & -i & 0 & 0 \\ i & 0 & 0 & 0 \end{bmatrix} \quad (21)$$

$$\alpha_3 = \mathbf{E}_{3i} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix} \quad (22)$$

$$\alpha_4 = \mathbf{E}_{30} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}. \quad (23)$$

The additional matrix

$$\alpha_5 = E_{20} = \rho_2 = \begin{bmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & -i \\ i & 0 & 0 & 0 \\ 0 & i & 0 & 0 \end{bmatrix} \quad (24)$$

is sometimes defined. Other sets of Dirac matrices are sometimes defined as

$$y_i = E_{2i} \quad (25)$$

$$y_4 = E_{30} \quad (26)$$

$$y_5 = -E_{10} \quad (27)$$

and

$$\delta_i = E_{3i} \quad (28)$$

for  $i = 1, 2, 3$  (Arfken 1985) and

$$\gamma_i = \begin{bmatrix} 0 & \sigma_i \\ -\sigma_i & 0 \end{bmatrix} \quad (29)$$

$$\gamma_4 = \begin{bmatrix} 1 & 0 \\ 2I & -1 \end{bmatrix} \quad (30)$$

for  $i = 1, 2, 3$  (Goldstein 1980).

Any of the 15 Dirac matrices (excluding the identity matrix) commute with eight Dirac matrices and anticommute with the other eight. Let  $M \equiv \frac{1}{2}(1 + E_{ij})$ , then

$$M^2 = M. \quad (31)$$

In addition

$$\begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} \times \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = 2i\sigma. \quad (32)$$

The products of  $\alpha_i$  and  $y_i$  satisfy

$$\alpha_1 \alpha_2 \alpha_3 \alpha_4 \alpha_5 = 1 \quad (33)$$

$$y_1 y_2 y_3 y_4 y_5 = 1. \quad (34)$$

The 16 Dirac matrices form six anticommuting sets of five matrices each:

1.  $\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5$ ,
2.  $y_1, y_2, y_3, y_4, y_5$ ,
3.  $\delta_1, \delta_2, \delta_3, \rho_1, \rho_2$ ,
4.  $\alpha_1, y_1, \delta_1, \sigma_2, \sigma_3$ ,
5.  $\alpha_2, y_2, \delta_2, \sigma_1, \sigma_3$ ,
6.  $\alpha_3, y_3, \delta_3, \sigma_1, \sigma_2$ .

#### Dirac's Theorem

A GRAPH with  $n \geq 3$  VERTICES in which each VERTEX has VALENCY  $\geq n/2$  has a HAMILTONIAN CIRCUIT.

see also HAMILTONIAN CIRCUIT

#### Direct Product (Group)

The expression of a GROUP as a product of SUBGROUPS. The CHARACTERS of the representations of a direct product are equal to the products of the CHARACTERS of the representations based on the individual sets of functions. For  $R_1$  and  $R_2$ ,

$$\chi(R_1 \otimes R_2) = \chi(R_1)\chi(R_2).$$

The representation of a direct product  $\Gamma_{AB}$  will contain the totally symmetric representation only if the irreducible  $\Gamma_A$  equals the irreducible  $\Gamma_B$ .

#### Direct Product (Matrix)

Given two  $n \times m$  MATRICES, their direct product  $C = A \otimes B$  is an  $(mn) \times (nm)$  MATRIX with elements defined by

$$C_{\alpha\beta} = A_{ij}B_{kl}, \quad (1)$$

where

$$\alpha \equiv n(i-1) + k \quad (2)$$

$$\beta \equiv n(j-1) + l. \quad (3)$$

For a  $2 \times 2$  MATRIX,

$$A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B \\ a_{21}B & a_{22}B \end{bmatrix} \quad (4)$$

$$= \begin{bmatrix} a_{11}b_{11} & a_{11}b_{12} & a_{12}b_{11} & a_{12}b_{12} \\ a_{11}b_{21} & a_{11}b_{22} & a_{12}b_{21} & a_{12}b_{22} \\ a_{21}b_{11} & a_{21}b_{12} & a_{22}b_{11} & a_{22}b_{12} \\ a_{21}b_{21} & a_{21}b_{22} & a_{22}b_{21} & a_{22}b_{22} \end{bmatrix}. \quad (5)$$

#### Direct Product (Set)

The direct product of two sets  $A$  and  $B$  is defined to be the set of all points  $(a, b)$  where  $a \in A$  and  $b \in B$ . The direct product is denoted  $A \times B$  or  $A \otimes B$  and is also called the CARTESIAN PRODUCT, since it originated in Descartes' formulation of analytic geometry. In the Cartesian view, points in the plane are specified by their vertical and horizontal coordinates, with points on a line being specified by just one coordinate. The main examples of direct products are EUCLIDEAN 3-space ( $\mathbb{R} \otimes \mathbb{R} \otimes \mathbb{R}$ , where  $\mathbb{R}$  are the REAL NUMBERS), and the plane ( $\mathbb{R} \times \mathbb{R}$ ).

**Direct Product (Tensor)**

For a first-RANK TENSOR (i.e., a VECTOR),

$$a'_i b'^j = \frac{\partial x_k}{\partial x'_i} a_k \frac{\partial x'_j}{\partial x_l} b^l = \frac{\partial x_k}{\partial x'_i} \frac{\partial x'_j}{\partial x_l} (a_k b^l), \quad (1)$$

which is a second-RANK TENSOR. The CONTRACTION of a direct product of first-RANK TENSORS is the SCALAR

$$\text{contr}(a'_i b'^j) = a'_i b'^i = a_k b^k. \quad (2)$$

For a second-RANK TENSOR,

$$A_j B_{kl} = C_j^{ikl} \quad (3)$$

$$C_j^{ikl'} = \frac{\partial x'_i}{\partial x_m} \frac{\partial x_n}{\partial x'_j} \frac{\partial x'_k}{\partial x_p} \frac{\partial x'_l}{\partial x_q} C_n^{mpq}. \quad (4)$$

For a general TENSOR, the direct product of two TENSORS is a TENSOR of RANK equal to the sum of the two initial RANKS. The direct product is ASSOCIATIVE, but not COMMUTATIVE.

Arfken, G. "Contraction, Direct Product." §3.2 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 124–126, 1985.

**Direct Search Factorization**

Direct search factorization is the simplest PRIME FACTORIZATION ALGORITHM. It consists of searching for factors of a number by systematically performing TRIAL DIVISIONS, usually using a sequence of increasing numbers. Multiples of small PRIMES are commonly excluded to reduce the number of trial DIVISORS, but just including them is sometimes faster than the time required to exclude them. This approach is very inefficient, and can be used only with fairly small numbers.

When using this method on a number  $n$ , only DIVISORS up to  $\lfloor \sqrt{n} \rfloor$  (where  $\lfloor x \rfloor$  is the FLOOR FUNCTION) need to be tested. This is true since if all INTEGERS less than this had been tried, then

$$\frac{n}{\lfloor \sqrt{n} \rfloor + 1} < \sqrt{n}. \quad (1)$$

In other words, all possible FACTORS have had their COFACTORS already tested. It is also true that, when the smallest PRIME FACTOR  $p$  of  $n$  is  $> \sqrt[3]{n}$ , then its COFACTOR  $m$  (such that  $n = pm$ ) must be PRIME. To prove this, suppose that the smallest  $p$  is  $> \sqrt[3]{n}$ . If  $m = ab$ , then the smallest value  $a$  and  $b$  could assume is  $p$ . But then

$$n = pm = pab = p^3 > n, \quad (2)$$

which cannot be true. Therefore,  $m$  must be PRIME, so

$$n = p_1 p_2. \quad (3)$$

see also PRIME FACTORIZATION ALGORITHMS, TRIAL DIVISION

**Direct Sum (Module)**

The direct sum of two MODULES  $V$  and  $W$  over the same RING  $R$  is given by  $V \otimes W$  with MODULE operations defined by

$$r \cdot (v, w) = (rv, rw)$$

$$(v, w) \oplus (y, z) = (v + y, w + z).$$

The direct sum of an arbitrary family of MODULES over the same RING is also defined. If  $J$  is the indexing set for the family of MODULES, then the direct sum is represented by the collection of functions with finite support from  $J$  to the union of all these MODULES such that the function sends  $j \in J$  to an element in the MODULE indexed by  $j$ .

The dimension of a direct sum is the product of the dimensions of the quantities summed. The significant property of the direct sum is that it is the coproduct in the category of MODULES. This general definition gives as a consequence the definition of the direct sum of ABELIAN GROUPS (since they are MODULES over the INTEGERS) and the direct sum of VECTOR SPACES (since they are MODULES over a FIELD).

**Directed Angle**

The symbol  $\angle ABC$  denotes the directed angle from  $AB$  to  $BC$ , which is the signed angle through which  $AB$  must be rotated about  $B$  to coincide with  $BC$ . Four points  $ABCD$  lie on a CIRCLE (i.e., are CONCYCLIC) IFF  $\angle ABC = \angle ADC$ . It is also true that

$$\angle l_1 l_2 + \angle l_2 l_1 = 0^\circ \text{ or } 180^\circ.$$

Three points  $A$ ,  $B$ , and  $C$  are COLLINEAR IFF  $\angle ABC = 0$ . For any four points,  $A$ ,  $B$ ,  $C$ , and  $D$ ,

$$\angle ABC + \angle CDA = \angle BAD + \angle DCB.$$

see also ANGLE, COLLINEAR, CONCYCLIC, MIQUEL EQUATION

**References**

Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, pp. 11–15, 1929.

**Directed Graph**

A GRAPH in which each EDGE is replaced by a directed EDGE, also called a DIGRAPH or REFLEXIVE GRAPH. A COMPLETE directed graph is called a TOURNAMENT. If  $G$  is an undirected connected GRAPH, then one can

always direct the circuit EDGES of  $G$  and leave the SEPARATING EDGES undirected so that there is a directed path from any node to another. Such a GRAPH is said to be transitive if the adjacency relation is transitive. The number of directed graphs of  $n$  nodes for  $n = 1, 2, \dots$  are 1, 1, 3, 16, 218, 9608, ... (Sloane's A000273).

see also ARBORESCENCE, CAYLEY GRAPH, INDEGREE, NETWORK, OUTDEGREE, SINK (DIRECTED GRAPH), SOURCE, TOURNAMENT

Sloane, N. J. A. Sequence A000273/M3032 in "An On-Line Version of the Encyclopedia of Integer Sequences."

#### Direction Cosine

Let  $a$  be the ANGLE between  $\mathbf{v}$  and  $\mathbf{x}$ ,  $b$  the ANGLE between  $\mathbf{v}$  and  $\mathbf{y}$ , and  $c$  the ANGLE between  $\mathbf{v}$  and  $\mathbf{z}$ . Then the direction cosines are equivalent to the  $(x, y, z)$  coordinates of a UNIT VECTOR  $\hat{\mathbf{v}}$ ,

$$\alpha \equiv \cos a \equiv \frac{\mathbf{v} \cdot \hat{\mathbf{x}}}{|\mathbf{v}|} \quad (1)$$

$$\beta \equiv \cos b \equiv \frac{\mathbf{v} \cdot \hat{\mathbf{y}}}{|\mathbf{v}|} \quad (2)$$

$$\gamma \equiv \cos c \equiv \frac{\mathbf{v} \cdot \hat{\mathbf{z}}}{|\mathbf{v}|}. \quad (3)$$

From these definitions, it follows that

$$\alpha^2 + \beta^2 + \gamma^2 = 1. \quad (4)$$

To find the JACOBIAN when performing integrals over direction cosines, use

$$\theta = \sin^{-1} \left( \sqrt{\alpha^2 + \beta^2} \right) \quad (5)$$

$$\phi = \tan^{-1} \left( \frac{\beta}{\alpha} \right) \quad (6)$$

$$\gamma = \sqrt{1 - \alpha^2 - \beta^2}. \quad (7)$$

The JACOBIAN is

$$\left| \frac{\partial(\theta, \phi)}{\partial(\alpha, \beta)} \right| = \left| \begin{array}{cc} \frac{\partial \theta}{\partial \alpha} & \frac{\partial \theta}{\partial \beta} \\ \frac{\partial \phi}{\partial \alpha} & \frac{\partial \phi}{\partial \beta} \end{array} \right|. \quad (8)$$

Using

$$\frac{d}{dx} (\sin^{-1} x) = \frac{1}{\sqrt{1-x^2}} \quad (9)$$

$$\frac{d}{dx} (\tan^{-1} x) = \frac{1}{1+x^2}, \quad (10)$$

$$\begin{aligned} \left| \frac{\partial(\theta, \phi)}{\partial(\alpha, \beta)} \right| &= \left| \begin{array}{cc} \frac{\frac{1}{2}(\alpha^2 + \beta^2)^{-1/2} 2\alpha}{\sqrt{1-\alpha^2-\beta^2}} & \frac{\frac{1}{2}(\alpha^2 + \beta^2)^{-1/2} 2\beta}{\sqrt{1-\alpha^2-\beta^2}} \\ \frac{-\alpha^{-2}\beta}{1+\frac{\beta^2}{\alpha^2}} & \frac{\alpha^{-1}}{1+\frac{\beta^2}{\alpha^2}} \end{array} \right| \\ &= \frac{1}{\sqrt{1-\alpha^2-\beta^2}} \frac{(\alpha^2 + \beta^2)^{-1/2}}{1+\frac{\beta^2}{\alpha^2}} \left( 1 + \frac{\beta^2}{\alpha^2} \right) \\ &= \frac{1}{\sqrt{(\alpha^2 + \beta^2)(1-\alpha^2-\beta^2)}}, \end{aligned} \quad (11)$$

so

$$\begin{aligned} d\Omega &= \sin \theta \, d\phi \, d\theta = \sqrt{\alpha^2 + \beta^2} \left| \frac{\partial(\theta, \phi)}{\partial(\alpha, \beta)} \right| d\alpha \, d\beta \\ &= \frac{d\alpha \, d\beta}{\sqrt{1-\alpha^2-\beta^2}} = \frac{d\alpha \, d\beta}{\gamma}. \end{aligned} \quad (12)$$

Direction cosines can also be defined between two sets of CARTESIAN COORDINATES,

$$\alpha_1 \equiv \hat{\mathbf{x}}' \cdot \hat{\mathbf{x}} \quad (13)$$

$$\alpha_2 \equiv \hat{\mathbf{x}}' \cdot \hat{\mathbf{y}} \quad (14)$$

$$\alpha_3 \equiv \hat{\mathbf{x}}' \cdot \hat{\mathbf{z}} \quad (15)$$

$$\beta_1 \equiv \hat{\mathbf{y}}' \cdot \hat{\mathbf{x}} \quad (16)$$

$$\beta_2 \equiv \hat{\mathbf{y}}' \cdot \hat{\mathbf{y}} \quad (17)$$

$$\beta_3 \equiv \hat{\mathbf{y}}' \cdot \hat{\mathbf{z}} \quad (18)$$

$$\gamma_1 \equiv \hat{\mathbf{z}}' \cdot \hat{\mathbf{x}} \quad (19)$$

$$\gamma_2 \equiv \hat{\mathbf{z}}' \cdot \hat{\mathbf{y}} \quad (20)$$

$$\gamma_3 \equiv \hat{\mathbf{z}}' \cdot \hat{\mathbf{z}}. \quad (21)$$

Projections of the unprimed coordinates onto the primed coordinates yield

$$\hat{\mathbf{x}}' = (\hat{\mathbf{x}}' \cdot \hat{\mathbf{x}})\hat{\mathbf{x}} + (\hat{\mathbf{x}}' \cdot \hat{\mathbf{y}})\hat{\mathbf{y}} + (\hat{\mathbf{x}}' \cdot \hat{\mathbf{z}})\hat{\mathbf{z}} = \alpha_1 \hat{\mathbf{x}} + \alpha_2 \hat{\mathbf{y}} + \alpha_3 \hat{\mathbf{z}} \quad (22)$$

$$\hat{\mathbf{y}}' = (\hat{\mathbf{y}}' \cdot \hat{\mathbf{x}})\hat{\mathbf{x}} + (\hat{\mathbf{y}}' \cdot \hat{\mathbf{y}})\hat{\mathbf{y}} + (\hat{\mathbf{y}}' \cdot \hat{\mathbf{z}})\hat{\mathbf{z}} = \beta_1 \hat{\mathbf{x}} + \beta_2 \hat{\mathbf{y}} + \beta_3 \hat{\mathbf{z}} \quad (23)$$

$$\hat{\mathbf{z}}' = (\hat{\mathbf{z}}' \cdot \hat{\mathbf{x}})\hat{\mathbf{x}} + (\hat{\mathbf{z}}' \cdot \hat{\mathbf{y}})\hat{\mathbf{y}} + (\hat{\mathbf{z}}' \cdot \hat{\mathbf{z}})\hat{\mathbf{z}} = \gamma_1 \hat{\mathbf{x}} + \gamma_2 \hat{\mathbf{y}} + \gamma_3 \hat{\mathbf{z}}, \quad (24)$$

and

$$x' = \mathbf{r} \cdot \hat{\mathbf{x}}' = \alpha_1 x + \alpha_2 y + \alpha_3 z \quad (25)$$

$$y' = \mathbf{r} \cdot \hat{\mathbf{y}}' = \beta_1 x + \beta_2 y + \beta_3 z \quad (26)$$

$$z' = \mathbf{r} \cdot \hat{\mathbf{z}}' = \gamma_1 x + \gamma_2 y + \gamma_3 z. \quad (27)$$

Projections of the primed coordinates onto the unprimed coordinates yield

$$\begin{aligned} \hat{\mathbf{x}} &= (\hat{\mathbf{x}} \cdot \hat{\mathbf{x}}')\hat{\mathbf{x}}' + (\hat{\mathbf{x}} \cdot \hat{\mathbf{y}}')\hat{\mathbf{y}}' + (\hat{\mathbf{x}} \cdot \hat{\mathbf{z}}')\hat{\mathbf{z}}' \\ &= \alpha_1 \hat{\mathbf{x}}' + \beta_1 \hat{\mathbf{y}}' + \gamma_1 \hat{\mathbf{z}}' \end{aligned} \quad (28)$$

$$\begin{aligned} \hat{\mathbf{y}} &= (\hat{\mathbf{y}} \cdot \hat{\mathbf{x}}')\hat{\mathbf{x}}' + (\hat{\mathbf{y}} \cdot \hat{\mathbf{y}}')\hat{\mathbf{y}}' + (\hat{\mathbf{y}} \cdot \hat{\mathbf{z}}')\hat{\mathbf{z}}' \\ &= \alpha_2 \hat{\mathbf{x}}' + \beta_2 \hat{\mathbf{y}}' + \gamma_2 \hat{\mathbf{z}}' \end{aligned} \quad (29)$$

$$\begin{aligned} \hat{\mathbf{z}} &= (\hat{\mathbf{z}} \cdot \hat{\mathbf{x}}')\hat{\mathbf{x}}' + (\hat{\mathbf{z}} \cdot \hat{\mathbf{y}}')\hat{\mathbf{y}}' + (\hat{\mathbf{z}} \cdot \hat{\mathbf{z}}')\hat{\mathbf{z}}' \\ &= \alpha_3 \hat{\mathbf{x}}' + \beta_3 \hat{\mathbf{y}}' + \gamma_3 \hat{\mathbf{z}}', \end{aligned} \quad (30)$$

and

$$x = \mathbf{r} \cdot \hat{\mathbf{x}} = \alpha_1 x + \beta_1 y + \gamma_1 z \quad (31)$$

$$y = \mathbf{r} \cdot \hat{\mathbf{y}} = \alpha_2 x + \beta_2 y + \gamma_2 z \quad (32)$$

$$z = \mathbf{r} \cdot \hat{\mathbf{z}} = \alpha_3 x + \beta_3 y + \gamma_3 z. \quad (33)$$

Using the orthogonality of the coordinate system, it must be true that

$$\hat{\mathbf{x}} \cdot \hat{\mathbf{y}} = \hat{\mathbf{y}} \cdot \hat{\mathbf{z}} = \hat{\mathbf{z}} \cdot \hat{\mathbf{x}} = 0 \quad (34)$$

$$\hat{\mathbf{x}} \cdot \hat{\mathbf{x}} = \hat{\mathbf{y}} \cdot \hat{\mathbf{y}} = \hat{\mathbf{z}} \cdot \hat{\mathbf{z}} = 1, \quad (35)$$

giving the identities

$$\alpha_l \alpha_m + \beta_l \beta_m + \gamma_l \gamma_m = 0 \quad (36)$$

for  $l, m = 1, 2, 3$  and  $l \neq m$ , and

$$\alpha_l^2 + \beta_l^2 + \gamma_l^2 = 1 \quad (37)$$

for  $l = 1, 2, 3$ . These two identities may be combined into the single identity

$$\alpha_l \alpha_m + \beta_l \beta_m + \gamma_l \gamma_m = \delta_{lm}, \quad (38)$$

where  $\delta_{lm}$  is the KRONECKER DELTA.

## Directional Derivative

$$\nabla_{\mathbf{u}} f \equiv \nabla f \cdot \frac{\mathbf{u}}{|\mathbf{u}|} \propto \lim_{h \rightarrow 0} \frac{f(\mathbf{x} + h\mathbf{u}) - f(\mathbf{x})}{h}. \quad (1)$$

$\nabla_{\mathbf{u}} f(x_0, y_0, z_0)$  is the rate at which the function  $w = f(x, y, z)$  changes at  $(x_0, y_0, z_0)$  in the direction  $\mathbf{u}$ . Let  $\mathbf{u}$  be a UNIT VECTOR in CARTESIAN COORDINATES, so

$$|\mathbf{u}| = \sqrt{u_x^2 + u_y^2 + u_z^2} = 1, \quad (2)$$

then

$$\nabla_{\mathbf{u}} f = \frac{\partial f}{\partial x} u_x + \frac{\partial f}{\partial y} u_y + \frac{\partial f}{\partial z} u_z. \quad (3)$$

The directional derivative is often written in the notation

$$\frac{d}{ds} \equiv \hat{\mathbf{s}} \cdot \nabla = s_x \frac{\partial}{\partial x} + s_y \frac{\partial}{\partial y} + s_z \frac{\partial}{\partial z}. \quad (4)$$

## Directly Similar

directly similar

Two figures are said to be SIMILAR when all corresponding ANGLES are equal, and are directly similar when all corresponding ANGLES are equal and described in the same rotational sense.

see also FUNDAMENTAL THEOREM OF DIRECTLY SIMILAR FIGURES, INVERSELY SIMILAR, SIMILAR

## Director Curve

The curve  $\mathbf{d}(u)$  in the RULED SURFACE parameterization

$$\mathbf{x}(u, v) = \mathbf{b}(u) + v\mathbf{d}(u).$$

## Dirichlet Beta Function

$$\beta(x) \equiv \sum_{n=0}^{\infty} (-1)^n (2n+1)^{-x} \quad (1)$$

$$\beta(x) = 2^{-x} \Phi(-1, x, \frac{1}{2}), \quad (2)$$

where  $\Phi$  is the LERCH TRANSCENDENT. The beta function can be written in terms of the HURWITZ ZETA FUNCTION  $\zeta(x, a)$  by

$$\beta(x) = \frac{1}{4^x} [\zeta(x, \frac{1}{4}) - \zeta(x, \frac{3}{4})]. \quad (3)$$

The beta function can be evaluated directly for POSITIVE ODD  $x$  as

$$\beta(2k+1) = \frac{(-1)^k E_{2k}}{2(2k)!} \left(\frac{1}{2}\pi\right)^{2k+1}, \quad (4)$$

where  $E_n$  is an EULER NUMBER. The beta function can be defined over the whole COMPLEX PLANE using ANALYTIC CONTINUATION,

$$\beta(1-z) = \left(\frac{2}{\pi}\right)^z \sin(\frac{1}{2}\pi z) \Gamma(z) \beta(z), \quad (5)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION.

Particular values for  $\beta$  are

$$\beta(1) = \frac{1}{4}\pi \quad (6)$$

$$\beta(2) \equiv K \quad (7)$$

$$\beta(3) = \frac{1}{32}\pi^3, \quad (8)$$

where  $K$  is CATALAN'S CONSTANT.

### Dirichlet Conditions

see DIRICHLET BOUNDARY CONDITIONS, DIRICHLET FOURIER SERIES CONDITIONS

### Dirichlet Divisor Problem

Let  $d(n) = \nu(n) = \sigma_0(n)$  be the number of DIVISORS of  $n$  (including  $n$  itself). For a PRIME  $p$ ,  $\nu(p) = 2$ . In general,

$$\sum_{k=1}^n \nu(k) = n \ln n + (2\gamma - 1)n + \mathcal{O}(n^\theta),$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT. Dirichlet originally gave  $\theta \approx 1/2$ . As of 1988, this had been reduced to  $\theta \approx 7/22$ .

see also DIVISOR FUNCTION

### Dirichlet Energy

Let  $h$  be a real-valued HARMONIC FUNCTION on a bounded DOMAIN  $\Omega$ , then the Dirichlet energy is defined as  $\int_{\Omega} |\nabla h|^2 dx$ , where  $\nabla$  is the GRADIENT.

see also ENERGY

### Dirichlet Eta Function

$$\eta(x) \equiv \sum_{n=1}^{\infty} (-1)^{n-1} n^{-x} = (1 - 2^{1-x})\zeta(x), \quad (1)$$

where  $n = 1, 2, \dots$ , and  $\zeta(x)$  is the RIEMANN ZETA FUNCTION. Particular values are given in Abramowitz and Stegun (1972, p. 811). The eta function is related to the RIEMANN ZETA FUNCTION and DIRICHLET LAMBDA FUNCTION by

$$\frac{\zeta(\nu)}{2^\nu} = \frac{\lambda(\nu)}{2^\nu - 1} = \frac{\eta(\nu)}{2^\nu - 2} \quad (2)$$

and

$$\zeta(\nu) + \eta(\nu) = 2\lambda(\nu) \quad (3)$$

(Spanier and Oldham 1987). The value  $\eta(1)$  may be computed by noting that the MACLAURIN SERIES for  $\ln(1+x)$  for  $-1 < x \leq 1$  is

$$\ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \dots \quad (4)$$

Therefore,

$$\begin{aligned} \ln 2 &= \ln(1+1) = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots \\ &= \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} = \eta(1). \end{aligned} \quad (5)$$

Values for EVEN INTEGERS are related to the analytical values of the RIEMANN ZETA FUNCTION.  $\eta(0)$  is defined to be  $\frac{1}{2}$ .

$$\begin{aligned} \eta(0) &= \frac{1}{2} \\ \eta(1) &= \ln 2 \\ \eta(2) &= \frac{\pi^2}{12} \\ \eta(3) &= 0.90154\dots \\ \eta(4) &= \frac{7\pi^4}{720}. \end{aligned}$$

#### Dirichlet's Formula

If  $g$  is continuous and  $\mu, \nu > 0$ , then

$$\begin{aligned} \int_0^t (t-\xi)^{\mu-1} d\xi \int_0^\xi (\xi-x)^{\nu-1} g(\xi, x) dx \\ = \int_0^t dx \int_x^t (t-\xi)^{\mu-1} (\xi-x)^{\nu-1} g(\xi, x) d\xi. \end{aligned}$$

#### Dirichlet Fourier Series Conditions

A piecewise regular function which

1. Has a finite number of finite discontinuities and
2. Has a finite number of extrema

can be expanded in a FOURIER SERIES which converges to the function at continuous points and the mean of the POSITIVE and NEGATIVE limits at points of discontinuity.

see also FOURIER SERIES

#### Dirichlet Function

Let  $c$  and  $d \neq c$  be REAL NUMBERS (usually taken as  $c = 1$  and  $d = 0$ ). The Dirichlet function is defined by

$$D(x) = \begin{cases} c & \text{for } x \text{ rational} \\ d & \text{for } x \text{ irrational.} \end{cases}$$

The function is CONTINUOUS at IRRATIONAL  $x$  and discontinuous at RATIONAL points. The function can be written analytically as

$$D(x) = \lim_{m,n \rightarrow \infty} \cos[(m! \pi x)^n].$$

Because the Dirichlet function cannot be plotted without producing a solid blend of lines, a modified version can be defined as

$$D_M(x) = \begin{cases} 0 & \text{for } x \text{ rational} \\ b & \text{for } x = a/b \text{ with } a/b \text{ a reduced fraction} \end{cases}$$

(Dixon 1991), illustrated above.

#### Dirichlet Integrals

There are several types of integrals which go under the name of a "Dirichlet integral." The integral

$$D[u] = \int_{\Omega} |\nabla u|^2 dV \quad (1)$$

appears in DIRICHLET'S PRINCIPLE.

The integral

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) \frac{\sin[(n + \frac{1}{2})x]}{\sin(\frac{1}{2}x)} dx, \quad (2)$$

where the kernel is the DIRICHLET KERNEL, gives the  $n$ th partial sum of the FOURIER SERIES.

Another integral is denoted

$$\delta_k \equiv \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{\sin \alpha_k \rho_k}{\rho_k} e^{i \rho_k \gamma_k} d\rho_k = \begin{cases} 0 & \text{for } |\gamma_k| > \alpha_k \\ 1 & \text{for } |\gamma_k| < \alpha_k \end{cases} \quad (3)$$

for  $k = 1, \dots, n$ .

There are two types of Dirichlet integrals which are denoted using the letters  $C$ ,  $D$ ,  $I$ , and  $J$ . The type 1 Dirichlet integrals are denoted  $I$ ,  $J$ , and  $IJ$ , and the type 2 Dirichlet integrals are denoted  $C$ ,  $D$ , and  $CD$ .

The type 1 integrals are given by

$$\begin{aligned} I &\equiv \iint \dots \int f(t_1 + t_2 + \dots + t_n) \\ &\quad \times t_1^{\alpha_1-1} t_2^{\alpha_2-1} \dots t_n^{\alpha_n-1} dt_1 dt_2 \dots dt_n \\ &= \frac{\Gamma(\alpha_1)\Gamma(\alpha_2)\dots\Gamma(\alpha_n)}{\Gamma(\sum_n \alpha_n)} \int_0^1 f(\tau) \tau^{(\sum_n \alpha_n)-1} d\tau, \quad (4) \end{aligned}$$

where  $\Gamma(z)$  is the GAMMA FUNCTION. In the case  $n = 2$ ,

$$I = \iint_T x^p y^q dx dy = \frac{p!q!}{(p+q+2)!} = \frac{B(p+1, q+1)}{p+q+2}, \quad (5)$$

where the integration is over the TRIANGLE  $T$  bounded by the  $x$ -axis,  $y$ -axis, and line  $x + y = 1$  and  $B(x, y)$  is the BETA FUNCTION.

The type 2 integrals are given for  $b$ -D vectors  $\mathbf{a}$  and  $\mathbf{r}$ , and  $0 \leq c \leq b$ ,

$$\begin{aligned} C_{\mathbf{a}}^{(b)}(\mathbf{r}, m) &= \frac{\Gamma(m+R)}{\Gamma(m) \prod_{i=1}^b \Gamma(r_i)} \\ &\quad \times \int_0^{a_1} \dots \int_0^{a_b} \frac{\prod_{i=1}^b x_i^{r_i-1} dx_i}{\left(1 + \sum_{i=1}^b x_i\right)^{m+R}} \quad (6) \end{aligned}$$

$$\begin{aligned} D_{\mathbf{a}}^{(b)}(\mathbf{r}, m) &= \frac{\Gamma(m+R)}{\Gamma(m) \prod_{i=1}^b \Gamma(r_i)} \\ &\quad \times \int_{a_1}^{\infty} \dots \int_{a_b}^{\infty} \frac{\prod_{i=1}^b x_i^{r_i-1} dx_i}{\left(1 + \sum_{i=1}^b x_i\right)^{m+R}} \quad (7) \end{aligned}$$

$$\begin{aligned} CD_{\mathbf{a}}^{(c, d-c)}(\mathbf{r}, m) &= \frac{\Gamma(m+R)}{\Gamma(m) \prod_{i=1}^b \Gamma(r_i)} \\ &\quad \times \int_0^{a_c} \int_{a_{c+1}}^{\infty} \dots \int_{a_b}^{\infty} \frac{\prod_{i=1}^b x_i^{r_i-1} dx_i}{\left(1 + \sum_{i=1}^b x_i\right)^{m+R}}, \quad (8) \end{aligned}$$

where

$$R \equiv \sum_{i=1}^k r_i \quad (9)$$

$$a_i \equiv \frac{p_i}{1 - \sum_{i=1}^k p_i}, \quad (10)$$

and  $p_i$  are the cell probabilities. For equal probabilities,  $a_i = 1$ . The Dirichlet  $D$  integral can be expanded as a MULTINOMIAL SERIES as

$$\begin{aligned} D_{\mathbf{a}}^{(b)}(\mathbf{r}, m) &= \frac{1}{\left(1 + \sum_{i=1}^b\right)^m} \\ &\quad \times \sum_{x_1 < r_1} \dots \sum_{x_b < r_b} \binom{m-1 + \sum_{a=1}^b x_a}{m-1, x_1, \dots, x_b} \\ &\quad \times \prod_{i=1}^b \left( \frac{a_i}{1 + \sum_{k=1}^b a_k} \right)^{x_i}. \quad (11) \end{aligned}$$

For small  $b$ ,  $C$  and  $D$  can be expressed analytically either partially or fully for general arguments and  $a_i = 1$ .

$$C_1^{(1)}(r_2; r_1) = \frac{\Gamma(r_1 + r_2) {}_2F_1(r_2, r_1 + r_2; 1 + r_2; -1)}{r_2 \Gamma(r_1) \Gamma(r_2)} \quad (12)$$

$$\begin{aligned} C_1^{(2)}(r_2, r_3; r_1) &= \frac{\Gamma(r_1 + r_2 + r_3)}{r_2 \Gamma(r_1) \Gamma(r_2) \Gamma(r_3)} \\ &\quad \times \int_0^1 {}_2F_1 y^{r_3-1} (1+y)^{-(r_1+r_2+r_3)} dy, \quad (13) \end{aligned}$$

where

$${}_2F_1 \equiv {}_2F_1(r_2, r_1 + r_2 + r_3; 1 + r_2, -(1+y)^{-1}) \quad (14)$$

is a HYPERGEOMETRIC FUNCTION.

$$D_1^{(1)}(r_2; r_1) = \frac{\Gamma(r_1 + r_2) {}_2F_1(r_1, r_1 + r_2; 1 + r_1; -1)}{r_1 \Gamma(r_1) \Gamma(r_2)} \quad (15)$$

$$\begin{aligned} D_1^{(2)}(r_2, r_3; r_1) &= \frac{\Gamma(r_1 + r_2 + r_3)}{(r_1 + r_3) \Gamma(r_1) \Gamma(r_2) \Gamma(r_3)} \\ &\quad \times \int_1^{\infty} {}_2F_1 y^{r_3-1} dy, \quad (16) \end{aligned}$$

where

$${}_2F_1 \equiv {}_2F_1(r_1 + r_3, r_1 + r_2 + r_3; 1 + r_1 + r_3; -1-y). \quad (17)$$

**Dirichlet Kernel**

The Dirichlet kernel  $D_n^M$  is obtained by integrating the CHARACTER  $e^{i(\xi, x)}$  over the BALL  $|\xi| \leq M$ ,

$$D_n^M = -\frac{1}{2\pi r} \frac{d}{dr} D_{n-2}^M.$$

The Dirichlet kernel of a DELTA SEQUENCE is given by

$$\delta_n(x) \equiv \frac{1}{2\pi} \frac{\sin[(n + \frac{1}{2})x]}{\sin(\frac{1}{2}x)}.$$

The integral of this kernel is called the DIRICHLET INTEGRAL  $D[u]$ .

see also DELTA SEQUENCE, DIRICHLET INTEGRALS, DIRICHLET'S LEMMA

**Dirichlet L-Series**

Series of the form

$$L_k(s, \chi) \equiv \sum_{n=1}^{\infty} \chi_k(n) n^{-s}, \quad (1)$$

where the CHARACTER (NUMBER THEORY)  $\chi_k(n)$  is an INTEGER function with period  $m$ . These series appear in number theory (they were used, for instance, to prove DIRICHLET'S THEOREM) and can be written as sums of LERCH TRANSCENDENTS with  $z$  a POWER of  $e^{2\pi i/m}$ . The DIRICHLET ETA FUNCTION

$$\eta(s) \equiv \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^s} = (1 - 2^{1-s})\zeta(s) \quad (2)$$

(for  $s \neq 1$ ) and DIRICHLET BETA FUNCTION

$$L_{-4}(s) = \beta(s) \equiv \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^s} \quad (3)$$

and RIEMANN ZETA FUNCTION

$$L_{+1}(s) = \zeta(s) \quad (4)$$

are Dirichlet series (Borwein and Borwein 1987, p. 289).  $\chi_k$  is called primitive if the CONDUCTOR  $f(\chi) = k$ . Otherwise,  $\chi_k$  is imprimitive. A primitive  $L$ -series modulo  $k$  is then defined as one for which  $\chi_k(n)$  is primitive. All imprimitive  $L$ -series can be expressed in terms of primitive  $L$ -series.

Let  $P = 1$  or  $P = \prod_{i=1}^t p_i$ , where  $p_i$  are distinct ODD PRIMES. Then there are three possible types of primitive  $L$ -series with REAL COEFFICIENTS. The requirement of REAL COEFFICIENTS restricts the CHARACTER to  $\chi_k(n) = \pm 1$  for all  $k$  and  $n$ . The three type are then

1. If  $k = P$  (e.g.,  $k = 1, 3, 5, \dots$ ) or  $k = 4P$  (e.g.,  $k = 4, 12, 20, \dots$ ), there is exactly one primitive  $L$ -series.

2. If  $k = 8P$  (e.g.,  $k = 8, 24, \dots$ ), there are two primitive  $L$ -series.

3. If  $k = 2P, Pp_i$ , or  $2^\alpha P$  where  $\alpha > 3$  (e.g.,  $k = 2, 6, 9, \dots$ ), there are no primitive  $L$ -series

(Zucker and Robertson 1976). All primitive  $L$ -series are algebraically independent and divide into two types according to

$$\chi_k(k-1) = \pm 1. \quad (5)$$

Primitive  $L$ -series of these types are denoted  $L_{\pm}$ . For a primitive  $L$ -series with REAL CHARACTER (NUMBER THEORY), if  $k = P$ , then

$$L_k = \begin{cases} L_{-k} & \text{if } P \equiv 3 \pmod{4} \\ L_k & \text{if } P \equiv 1 \pmod{4}. \end{cases} \quad (6)$$

If  $k = 4P$ , then

$$L_k = \begin{cases} L_{-k} & \text{if } P \equiv 1 \pmod{4} \\ L_k & \text{if } P \equiv 3 \pmod{4}, \end{cases} \quad (7)$$

and if  $k = 8P$ , then there is a primitive function of each type (Zucker and Robertson 1976).

The first few primitive NEGATIVE  $L$ -series are  $L_{-3}, L_{-4}, L_{-7}, L_{-8}, L_{-11}, L_{-15}, L_{-19}, L_{-20}, L_{-23}, L_{-24}, L_{-31}, L_{-35}, L_{-39}, L_{-40}, L_{-43}, L_{-47}, L_{-51}, L_{-52}, L_{-55}, L_{-56}, L_{-59}, L_{-67}, L_{-68}, L_{-71}, L_{-79}, L_{-83}, L_{-84}, L_{-87}, L_{-88}, L_{-91}, L_{-95}, \dots$  (Sloane's A003657), corresponding to the negated discriminants of imaginary quadratic fields. The first few primitive POSITIVE  $L$ -series are  $L_{+1}, L_{+5}, L_{+8}, L_{+12}, L_{+13}, L_{+17}, L_{+21}, L_{+24}, L_{+28}, L_{+29}, L_{+33}, L_{+37}, L_{+40}, L_{+41}, L_{+44}, L_{+53}, L_{+56}, L_{+57}, L_{+60}, L_{+61}, L_{+65}, L_{+69}, L_{+73}, L_{+76}, L_{+77}, L_{+85}, L_{+88}, L_{+89}, L_{+92}, L_{+93}, L_{+97}, \dots$  (Sloane's A046113).

The KRONECKER SYMBOL is a REAL CHARACTER modulo  $k$ , and is in fact essentially the only type of REAL primitive CHARACTER (Ayoub 1963). Therefore,

$$L_{+d}(s) = \sum_{n=1}^{\infty} (d|n) n^{-s} \quad (8)$$

$$L_{-d}(s) = \sum_{n=1}^{\infty} (-d|n) n^{-s}, \quad (9)$$

where  $(d|n)$  is the KRONECKER SYMBOL. The functional equations for  $L_{\pm}$  are

$$L_{-k}(s) = 2^s \pi^{s-1} k^{-s+1/2} \Gamma(1-s) \cos(\frac{1}{2}s\pi) L_{-k}(1-s) \quad (10)$$

$$L_{+k}(s) = 2^s \pi^{s-1} k^{-s+1/2} \Gamma(1-s) \sin(\frac{1}{2}s\pi) L_{+k}(1-s). \quad (11)$$

For  $m$  a POSITIVE INTEGER

$$L_{+k}(-2m) = 0 \quad (12)$$

$$L_{-k}(1-2m) = 0 \quad (13)$$

$$L_{+k}(2m) = Rk^{-1/2}\pi^{2m} \quad (14)$$

$$L_{-k}(2m-1) = R'k^{-1/2}\pi^{2m-1} \quad (15)$$

$$L_{+k}(1-2m) = \frac{(-1)^m(2m-1)!R}{(2k)^{2m-1}} \quad (16)$$

$$L_{-k}(-2k) = \frac{(-1)^m R'(2m)!}{(2k)^{2m}}, \quad (17)$$

where  $R$  and  $R'$  are RATIONAL NUMBERS.  $L_{+k}(1)$  can be expressed in terms of transcendentals by

$$L_d(1) = h(d)\kappa(d), \quad (18)$$

where  $h(d)$  is the CLASS NUMBER and  $\kappa(d)$  is the DIRICHLET STRUCTURE CONSTANT. Some specific values of primitive  $L$ -series are

$$L_{-15}(1) = \frac{2\pi}{\sqrt{15}}$$

$$L_{-11}(1) = \frac{\pi}{\sqrt{11}}$$

$$L_{-8}(1) = \frac{\pi}{2\sqrt{2}}$$

$$L_{-7}(1) = \frac{\pi}{\sqrt{7}}$$

$$L_{-4}(1) = \frac{1}{4}\pi$$

$$L_{-3}(1) = \frac{\pi}{3\sqrt{3}}$$

$$L_{+5}(1) = \frac{2}{\sqrt{5}} \ln \left( \frac{1+\sqrt{5}}{2} \right)$$

$$L_{+8}(1) =$$

$$L_{+12}(1) = \frac{\ln(2+\sqrt{3})}{\sqrt{3}}$$

$$L_{+13}(1) = \frac{2}{\sqrt{13}} \ln \left( \frac{3+\sqrt{13}}{2} \right)$$

$$L_{+17}(1) = \frac{2}{\sqrt{17}} \ln(4+\sqrt{17})$$

$$L_{+21}(1) = \frac{2}{\sqrt{21}} \ln \left( \frac{5+\sqrt{21}}{2} \right)$$

$$L_{+24}(1) = \frac{\ln(5+2\sqrt{6})}{\sqrt{6}}.$$

No general forms are known for  $L_{-k}(2m)$  and  $L_{+k}(2m-1)$  in terms of known transcendentals. For example,

$$L_{-4}(2) = \beta(2) \equiv K, \quad (19)$$

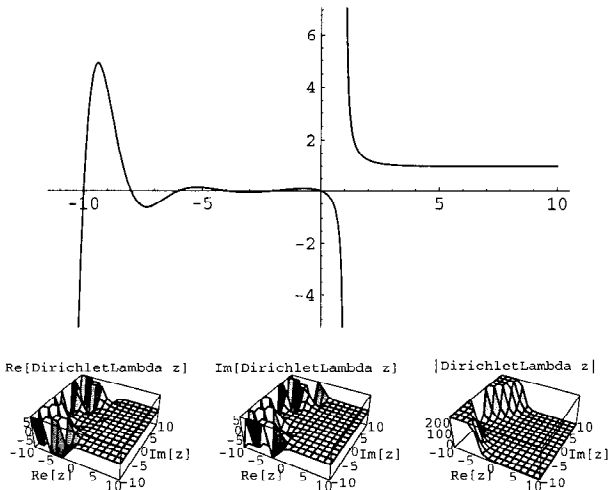

where  $K$  is defined as CATALAN'S CONSTANT.

## Dirichlet Lambda Function

$$\lambda(x) \equiv \sum_{n=0}^{\infty} (2n+1)^{-x} = (1-2^{-x})\zeta(x) \quad (1)$$

for  $x = 2, 3, \dots$ , where  $\zeta(x)$  is the RIEMANN ZETA FUNCTION. The function is undefined at  $x = 1$ . It can be computed in closed form where  $\zeta(x)$  can, that is for EVEN POSITIVE  $n$ . It is related to the RIEMANN ZETA FUNCTION and DIRICHLET ETA FUNCTION by

$$\frac{\zeta(\nu)}{2^\nu} = \frac{\lambda(\nu)}{2^\nu - 1} = \frac{\eta(\nu)}{2^\nu - 2} \quad (2)$$

and

$$\zeta(\nu) + \eta(\nu) = 2\lambda(\nu) \quad (3)$$

(Spanier and Oldham 1987). Special values of  $\lambda(n)$  include

$$\lambda(2) = \frac{\pi^2}{8} \quad (4)$$

$$\lambda(4) = \frac{\pi^4}{96}. \quad (5)$$

### Dirichlet's Principle

Also known as THOMSON'S PRINCIPLE. There exists a function  $u$  that minimizes the functional

$$D[u] = \int_{\Omega} |\nabla u|^2 dV$$

(called the DIRICHLET INTEGRAL) for  $\Omega \subset \mathbb{R}^2$  or  $\mathbb{R}^3$  among all the functions  $u \in C^{(1)}(\Omega) \cap C^{(0)}(\bar{\Omega})$  which take on given values  $f$  on the boundary  $\partial\Omega$  of  $\Omega$ , and that function  $u$  satisfies  $\nabla^2 = 0$  in  $\Omega$ ,  $u|_{\partial\Omega} = f$ ,  $u \in C^{(2)}(\Omega) \cap C^{(0)}(\bar{\Omega})$ . Weierstraß showed that Dirichlet's argument contained a subtle fallacy. As a result, it can be claimed only that there exists a lower bound to which  $D[u]$  comes arbitrarily close without being forced to actually reach it. Kneser, however, obtained a valid proof of Dirichlet's principle.

see also DIRICHLET'S BOX PRINCIPLE, DIRICHLET INTEGRALS

### Dirichlet Region

see VORONOI POLYGON

### Dirichlet Series

A sum  $\sum a_n e^{\lambda_n z}$ , where  $a_n$  and  $z$  are COMPLEX and  $\lambda_n$  is REAL and MONOTONIC increasing.

see also DIRICHLET L-SERIES

### Dirichlet Structure Constant

$$\kappa(d) = \begin{cases} \frac{2 \ln \eta(d)}{\sqrt{d}} & \text{for } d > 0 \\ \frac{2\pi}{w(d)\sqrt{|d|}} & \text{for } d < 0, \end{cases}$$

where  $\eta(d)$  is the FUNDAMENTAL UNIT and  $w(d)$  is the number of substitutions which leave the binary quadratic form unchanged

$$w(d) = \begin{cases} 6 & \text{for } d = -3 \\ 4 & \text{for } d = -4 \\ 2 & \text{otherwise.} \end{cases}$$

see also CLASS NUMBER, DIRICHLET L-SERIES

### Dirichlet Tessellation

see VORONOI DIAGRAM

### Dirichlet's Test

Let

$$\left| \sum_{n=1}^p a_n \right| < K,$$

where  $K$  is independent of  $p$ . Then if  $f_n \geq f_{n+1} > 0$  and

$$\lim_{n \rightarrow \infty} f_n = 0,$$

it follows that

$$\sum_{n=1}^{\infty} a_n f_n$$

CONVERGES.

see also CONVERGENCE TESTS

### Dirichlet's Theorem

Given an ARITHMETIC SERIES of terms  $an+b$ , for  $n = 1, 2, \dots$ , the series contains an infinite number of PRIMES if  $a$  and  $b$  are RELATIVELY PRIME, i.e.,  $(a, b) = 1$ . Dirichlet proved this theorem using DIRICHLET L-SERIES.

**Dirty Beam**

The FOURIER TRANSFORM of the  $(u, v)$  sampling distribution in synthesis imaging

$$b' = \mathcal{F}^{-1}(S), \quad (1)$$

also called the SYNTHESIZED BEAM. It is called a "beam" by way of analogy with the DIRTY MAP

$$\begin{aligned} I' &= \mathcal{F}^{-1}(VS) = \mathcal{F}^{-1}[V] * \mathcal{F}^{-1}[S] \\ &= I * \mathcal{F}^{-1}(S) \equiv I * b', \end{aligned} \quad (2)$$

where  $*$  denotes CONVOLUTION. Here,  $I'$  is the intensity which would be observed for an extended source by an antenna with response pattern  $b_1$ ,

$$I' = b_1(\theta'') * I(\theta''). \quad (3)$$

The dirty beam is often a complicated function. In order to avoid introducing any high spatial frequency features when CLEANing, an elliptical Gaussian is usually fit to the dirty beam, producing a CLEAN BEAM which is CONVOLVED with the final iteration.

see also CLEAN ALGORITHM, CLEAN MAP, DIRTY MAP

**Dirty Map**

From the van Cittert-Zernicke theorem, the relationship between observed visibility function  $V(u, v)$  and source brightness  $I(\xi, \eta)$  in synthesis imaging is given by

$$\begin{aligned} I(\xi, \eta) &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} V(u, v) e^{2\pi i(\xi u + \eta v)} du dv \\ &= \mathcal{F}^{-1}[V(u, v)]. \end{aligned} \quad (1)$$

But the visibility function is sampled only at discrete points  $S(u, v)$  (finite sampling), so only an approximation to  $I$ , called the "dirty map" and denoted  $I'$ , is measured. It is given by

$$\begin{aligned} I'(\xi, \eta) &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} S(u, v) V(u, v) e^{2\pi i(\xi u + \eta v)} du dv \\ &= \mathcal{F}^{-1}[VS], \end{aligned} \quad (2)$$

where  $S(u, v)$  is the sampling function and  $V(u, v)$  is the observed visibility function. Let  $*$  denote CONVOLUTION and rearrange the CONVOLUTION THEOREM,

$$\mathcal{F}[f * g] = \mathcal{F}[f]\mathcal{F}[g] \quad (3)$$

into the form

$$\mathcal{F}[\mathcal{F}^{-1}[f] * \mathcal{F}^{-1}[g]] = fg, \quad (4)$$

from which it follows that

$$\mathcal{F}^{-1}[f] * \mathcal{F}^{-1}[g] = \mathcal{F}^{-1}[fg]. \quad (5)$$

Now note that

$$I = \mathcal{F}^{-1}[V] \quad (6)$$

is the CLEAN MAP, and define the "DIRTY BEAM" as the inverse FOURIER TRANSFORM of the sampling function,

$$b' \equiv \mathcal{F}^{-1}[S]. \quad (7)$$

The dirty map is then given by

$$I' = \mathcal{F}^{-1}[VS] = \mathcal{F}^{-1}[V] * \mathcal{F}^{-1}[S] = I * b'. \quad (8)$$

In order to deconvolve the desired CLEAN MAP  $I$  from the measured dirty map  $I'$  and the known DIRTY BEAM  $b'$ , the CLEAN ALGORITHM is often used.

see also CLEAN ALGORITHM, CLEAN MAP, DIRTY BEAM

**Disc**

see DISK

**Disconnected Form**

A FORM which is the sum of two FORMS involving separate sets of variables.

**Disconnectivity**

Disconnectivities are mathematical entities which stand in the way of a SPACE being contractible (i.e., shrunk to a point, where the shrinking takes place inside the SPACE itself). When dealing with TOPOLOGICAL SPACES, a disconnectivity is interpreted as a "HOLE" in the space. Disconnectivities in SPACE are studied through the EXTENSION PROBLEM or the LIFTING PROBLEM.

see also EXTENSION PROBLEM, HOLE, LIFTING PROBLEM

**Discontinuity**

A point at which a mathematical object is DISCONTINUOUS.

**Discontinuous**

Not CONTINUOUS. A point at which a function is discontinuous is called a DISCONTINUITY, or sometimes a JUMP.

### Discrepancy Theorem

Let  $s_1, s_2, \dots$  be an infinite series of real numbers lying between 0 and 1. Then corresponding to any arbitrarily large  $K$ , there exists a positive integer  $n$  and two subintervals of equal length such that the number of  $s_\nu$  with  $\nu = 1, 2, \dots, n$  which lie in one of the subintervals differs from the number of such  $s_\nu$  that lie in the other subinterval by more than  $K$  (van der Corput 1935ab, van Aardenne-Ehrenfest 1945, 1949, Roth 1954).

This statement can be refined as follows. Let  $N$  be a large integer and  $s_1, s_2, \dots, s_N$  be a sequence of  $N$  real numbers lying between 0 and 1. Then for any integer  $1 \leq n \leq N$  and any real number  $\alpha$  satisfying  $0 < \alpha < 1$ , let  $D_n(\alpha)$  denote the number of  $s_\nu$  with  $\nu = 1, 2, \dots, n$  that satisfy  $0 \leq s_\nu < \alpha$ . Then there exist  $n$  and  $\alpha$  such that

$$|D_n(\alpha) - n\alpha| > c_1 \frac{\ln \ln N}{\ln \ln \ln N}$$

where  $c_1$  is a positive constant.

This result can be further strengthened, which is most easily done by reformulating the problem. Let  $N > 1$  be an integer and  $P_1, P_2, \dots, P_N$  be  $N$  (not necessarily distinct) points in the square  $0 \leq x \leq 1, 0 \leq y \leq 1$ . Then

$$\int_0^1 \int_0^1 [S(x, y) - Nxy]^2 dx dy > c_2 \ln N,$$

where  $c_2$  is a positive constant and  $S(u, v)$  is the number of points in the rectangle  $0 \leq x < u, 0 \leq y < v$  (Roth 1954). Therefore,

$$|S(x, y) - Nxy| > c_3 \sqrt{\ln N},$$

and the original result can be stated as the fact that there exist  $n$  and  $\alpha$  such that

$$|D_n(\alpha) - n\alpha| > c_4 \sqrt{\ln N}.$$

The randomly distributed points shown in the above squares have  $|S(x, y) - Nxy|^2 = 6.40$  and  $9.11$ , respectively.

Similarly, the discrepancy of a set of  $N$  points in a unit  $d$ -HYPERCUBE satisfies

$$|S(x, y) - Nxy| > c(\ln N)^{(d-1)/2}$$

(Roth 1954, 1976, 1979, 1980).

### Discrete Fourier Transform

The FOURIER TRANSFORM is defined as

$$f(\nu) = \mathcal{F}[f(t)] = \int_{-\infty}^{\infty} f(t) e^{-2\pi i \nu t} dt. \quad (1)$$

Now consider generalization to the case of a discrete function,  $f(t) \rightarrow f(t_k)$  by letting  $f_k \equiv f(t_k)$ , where  $t_k \equiv k\Delta$ , with  $k = 0, \dots, N-1$ . Choose the frequency step such that

$$\nu_n = \frac{n}{N\Delta}, \quad (2)$$

with  $n = -N/2, \dots, 0, \dots, N/2$ . There are  $N+1$  values of  $n$ , so there is one relationship between the frequency components. Writing this out as per Press *et al.* (1989)

$$\mathcal{F}[f(t)] = \sum_{k=0}^{N-1} f_k e^{-2\pi i (n/N\Delta) k \Delta} \Delta = \Delta \sum_{k=0}^{N-1} f_k e^{-2\pi i n k / N}, \quad (3)$$

and

$$F_n \equiv \sum_{k=0}^{N-1} f_k e^{-2\pi i n k / N}. \quad (4)$$

The inverse transform is

$$f_k = \frac{1}{N} \sum_{n=0}^{N-1} F_n e^{2\pi i n k / N}. \quad (5)$$

Note that  $F_{-n} = F_{N-n}$ ,  $n = 1, 2, \dots$ , so an alternate formulation is

$$\nu_n = \frac{n}{N\Delta}, \quad (6)$$

where the NEGATIVE frequencies  $-\nu_c < \nu < 0$  have  $N/2 + 1 \leq n \leq N - 1$ , POSITIVE frequencies  $0 < \nu < \nu_c$  have  $1 \leq n \leq N/2 - 1$ , with zero frequency  $n = 0$ .  $n = N/2$  corresponds to both  $\nu = \nu_c$  and  $\nu = -\nu_c$ . The discrete Fourier transform can be computed using a FAST FOURIER TRANSFORM.

The discrete Fourier transform is a special case of the  $z$ -TRANSFORM.

### Discrete Mathematics

The branch of mathematics dealing with objects which can assume only certain "discrete" values. Discrete objects can be characterized by INTEGERS (or RATIONAL NUMBERS), whereas continuous objects require REAL NUMBERS. The study of how discrete objects combine with one another and the probabilities of various outcomes is known as COMBINATORICS.

see also COMBINATORICS

### Discrete Set

A finite SET or an infinitely COUNTABLE SET of elements.

### Discrete Uniform Distribution

see EQUALLY LIKELY OUTCOMES DISTRIBUTION

### Discriminant

A discriminant is a quantity (usually invariant under certain classes of transformations) which characterizes certain properties of a quantity's ROOTS. The concept of the discriminant is used for BINARY QUADRATIC FORMS, ELLIPTIC CURVES, METRICS, MODULES, POLYNOMIALS, QUADRATIC CURVES, QUADRATIC FIELDS, QUADRATIC FORMS, and in the SECOND DERIVATIVE TEST.

#### Discriminant (Binary Quadratic Form)

The discriminant of a BINARY QUADRATIC FORM

$$4u^2 + buv + cv^2$$

is defined by

$$d \equiv b^2 - 4ac.$$

It is equal to four times the corresponding DETERMINANT.

see also CLASS NUMBER

#### Discriminant (Elliptic Curve)

AN ELLIPTIC CURVE is of the form

$$y^2 = x^3 + a_2x^2 + a_1x + a_0.$$

Let the ROOTS of  $y^2$  be  $r_1, r_2$ , and  $r_3$ . The discriminant is then defined as

$$\Delta = k(r_1 - r_2)^2(r_1 - r_3)^2(r_2 - r_3)^2.$$

see also FREY CURVE, MINIMAL DISCRIMINANT

#### Discriminant (Metric)

Given a METRIC  $g_{\alpha\beta}$ , the discriminant is defined by

$$g \equiv \det(g_{\alpha\beta}) = \begin{vmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{vmatrix} = g_{11}g_{22} - (g_{12})^2. \quad (1)$$

Let  $g$  be the discriminant and  $\bar{g}$  the transformed discriminant, then

$$\bar{g} = D^2 g \quad (2)$$

$$g = \bar{D}^2 \bar{g}, \quad (3)$$

where

$$D \equiv \frac{\partial(u^1, u^2)}{\partial(\bar{u}^1, \bar{u}^2)} = \begin{vmatrix} \frac{\partial u^1}{\partial \bar{u}^1} & \frac{\partial u^1}{\partial \bar{u}^2} \\ \frac{\partial u^2}{\partial \bar{u}^1} & \frac{\partial u^2}{\partial \bar{u}^2} \end{vmatrix} \quad (4)$$

$$\bar{D} \equiv \frac{\partial(\bar{u}^1, \bar{u}^2)}{\partial(u^1, u^2)} = \begin{vmatrix} \frac{\partial \bar{u}^1}{\partial u^1} & \frac{\partial \bar{u}^1}{\partial u^2} \\ \frac{\partial \bar{u}^2}{\partial u^1} & \frac{\partial \bar{u}^2}{\partial u^2} \end{vmatrix}. \quad (5)$$

**Discriminant (Module)**

Let a MODULE  $M$  in an INTEGRAL DOMAIN  $D_1$  for  $R(\sqrt{D})$  be expressed using a two-element basis as

$$M = [\xi_1, \xi_2],$$

where  $\xi_1$  and  $\xi_2$  are in  $D_1$ . Then the DIFFERENT of the MODULE is defined as

$$\Delta = \Delta(M) = \begin{vmatrix} \xi_1 & \xi_2 \\ \xi'_1 & \xi'_2 \end{vmatrix} = \xi_1 \xi'_2 - \xi'_1 \xi_2$$

and the discriminant is defined as the square of the DIFFERENT (Cohn 1980).

For IMAGINARY QUADRATIC FIELDS  $\mathbb{Q}(\sqrt{n})$  (with  $n < 0$ ), the discriminants are given in the following table.

-1	-2 <sup>2</sup>	-33	-2 <sup>2</sup> · 3 · 11	-67	-67
-2	-2 <sup>3</sup>	-34	-2 <sup>3</sup> · 17	-69	-2 <sup>2</sup> · 3 · 23

**Discriminant (Polynomial)**

The PRODUCT of the SQUARES of the differences of the POLYNOMIAL ROOTS  $x_i$ . For a POLYNOMIAL of degree  $n$ ,

$$D_n \equiv \prod_{\substack{i,j \\ i < j}}^n (x_i - x_j)^2. \quad (1)$$

The discriminant of the QUADRATIC EQUATION

$$ax^2 + bx + c = 0 \quad (2)$$

is usually taken as

$$D = b^2 - 4ac. \quad (3)$$

However, using the general definition of the POLYNOMIAL DISCRIMINANT gives

$$D \equiv \prod_{i < j} (z_i - z_j)^2 = \frac{b^2 - 4ac}{a^2}, \quad (4)$$

where  $z_i$  are the ROOTS.

The discriminant of the CUBIC EQUATION

$$z^3 + a_2 z^2 + a_1 z + a_0 = 0 \quad (5)$$

is commonly defined as

$$D \equiv Q^3 + R^2, \quad (6)$$

where

$$Q \equiv \frac{3a_1 - a_2^2}{9} \quad (7)$$

$$R \equiv \frac{9a_2 a_1 - 27a_0 - 2a_2^3}{54}. \quad (8)$$

However, using the general definition of the polynomial discriminant for the standard form CUBIC EQUATION

$$z^3 + pz = q \quad (9)$$

gives

$$D \equiv \prod_{i < j} (z_i - z_j)^2 = P^2 = -4p^3 - 27q^2, \quad (10)$$

where  $z_i$  are the ROOTS and

$$P = (z_1 - z_2)(z_2 - z_3)(z_1 - z_3). \quad (11)$$

The discriminant of a QUARTIC EQUATION

$$x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 = 0 \quad (12)$$

is

$$\begin{aligned} & -27a_1^4 + 18a_3a_2a_1^3 - 4a_3^3a_1^3 - 4a_2^3a_1^2 + a_3^2a_2^2a_1^2 \\ & + a_0(144a_2a_1^2 - 6a_3^2a_1^2 - 80a_3a_2^2a_1 + 18a_3^3a_2a_1 + 16a_2^4 \\ & - 4a_3^2a_2^3) + a_0^2(-192a_3a_1 - 128a_2^2 + 144a_3^2a_2 - 27a_3^4) \\ & - 256a_0^3 \quad (13) \end{aligned}$$

(Beeler *et al.* 1972, Item 4).

### Discriminant (Quadratic Curve)

Given a general QUADRATIC CURVE

$$Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0, \quad (1)$$

the quantity  $X$  is known as the discriminant, where

$$X \equiv B^2 - 4AC, \quad (2)$$

and is invariant under ROTATION. Using the COEFFICIENTS from QUADRATIC EQUATIONS for a rotation by an angle  $\theta$ ,

$$\begin{aligned} A' &= \frac{1}{2}A[1 + \cos(2\theta)] + \frac{1}{2}B\sin(2\theta) + \frac{1}{2}C[1 - \cos(2\theta)] \\ &= \frac{A+C}{2} + \frac{B}{2}\sin(2\theta) + \frac{A-C}{2}\cos(2\theta) \quad (3) \end{aligned}$$

$$B' = G\cos\left(2\theta + \delta - \frac{\pi}{2}\right) = G\sin(2\theta + \delta) \quad (4)$$

$$\begin{aligned} C' &= \frac{1}{2}A[1 - \cos(2\theta)] - \frac{1}{2}B\sin(2\theta) + \frac{1}{2}C[1 + \cos(2\theta)] \\ &= \frac{A+C}{2} - \frac{B}{2}\sin(2\theta) + \frac{C-A}{2}\cos(2\theta). \quad (5) \end{aligned}$$

Now let

$$G \equiv \sqrt{B^2 + (A-C)^2} \quad (6)$$

$$\delta \equiv \tan^{-1}\left(\frac{B}{C-A}\right) \quad (7)$$

$$\delta_2 \equiv \tan^{-1}\left(\frac{A-C}{B}\right) = -\cot^{-1}\left(\frac{B}{C-A}\right), \quad (8)$$

and use

$$\cot^{-1}(x) = \frac{1}{2}\pi - \tan^{-1}(x) \quad (9)$$

$$\delta_2 = \delta - \frac{1}{2}\pi \quad (10)$$

to rewrite the primed variables

$$A' = \frac{A+C}{2} + \frac{1}{2}G\cos(2\theta + \delta) \quad (11)$$

$$B' = B\cos(2\theta) + (C-A)\sin(2\theta) = G\cos(2\theta + \delta_2) \quad (12)$$

$$C' = \frac{A+C}{2} - \frac{1}{2}G\cos(2\theta + \delta). \quad (13)$$

From (11) and (13), it follows that

$$4A'C' = (A+C)^2 - G^2\cos(2\theta + \delta). \quad (14)$$

Combining with (12) yields, for an arbitrary  $\theta$

$$\begin{aligned} X &\equiv B'^2 - 4A'C' \\ &= G^2\sin^2(2\theta + \delta) + G^2\cos^2(2\theta + \delta) - (A+C)^2 \\ &= G^2 - (A+C)^2 = B^2 + (A-C)^2 - (A+C)^2 \\ &= B^2 - 4AC, \quad (15) \end{aligned}$$

which is therefore invariant under rotation. This invariant therefore provides a useful shortcut to determining the shape represented by a QUADRATIC CURVE. Choosing  $\theta$  to make  $B' = 0$  (see QUADRATIC EQUATION), the curve takes on the form

$$A'x^2 + C'y^2 + D'x + E'y + F = 0. \quad (16)$$

COMPLETING THE SQUARE and defining new variables gives

$$A'x'^2 + C'y'^2 = H. \quad (17)$$

Without loss of generality, take the sign of  $H$  to be positive. The discriminant is

$$X = B'^2 - 4A'C' = -4A'C'. \quad (18)$$

Now, if  $-4A'C' < 0$ , then  $A'$  and  $C'$  both have the same sign, and the equation has the general form of an ELLIPSE (if  $A'$  and  $B'$  are positive). If  $-4A'C' > 0$ , then  $A'$  and  $C'$  have opposite signs, and the equation has the general form of a HYPERBOLA. If  $-4A'C' = 0$ , then either  $A'$  or  $C'$  is zero, and the equation has the general form of a PARABOLA (if the NONZERO  $A'$  or  $C'$  is positive). Since the discriminant is invariant, these conclusions will also hold for an arbitrary choice of  $\theta$ , so they also hold when  $-4A'C'$  is replaced by the original  $B^2 - 4AC$ . The general result is

1. If  $B^2 - 4AC < 0$ , the equation represents an ELLIPSE, a CIRCLE (degenerate ELLIPSE), a POINT (degenerate CIRCLE), or has no graph.
2. If  $B^2 - 4AC > 0$ , the equation represents a HYPERBOLA or pair of intersecting lines (degenerate HYPERBOLA).
3. If  $B^2 - 4AC = 0$ , the equation represents a PARABOLA, a LINE (degenerate PARABOLA), a pair of PARALLEL lines (degenerate PARABOLA), or has no graph.

**Disk**

An  $n$ -D disk (or DISC) of RADIUS  $r$  is the collection of points of distance  $\leq r$  (CLOSED DISK) or  $< r$  (OPEN DISK) from a fixed point in EUCLIDEAN  $n$ -space. A disk is the SHADOW of a BALL on a PLANE PERPENDICULAR to the BALL-RADIANT POINT line.

The  $n$ -disk for  $n \geq 3$  is called a BALL, and the boundary of the  $n$ -disk is a  $(n-1)$ -HYPERSPHERE. The standard  $n$ -disk, denoted  $\mathbb{D}^n$  (or  $\mathbb{B}^n$ ), has its center at the ORIGIN and has RADIUS  $r = 1$ .

see also BALL, CLOSED DISK, DISK COVERING PROBLEM, FIVE DISKS PROBLEM, HYPERSPHERE, MERGELYAN-WESLER THEOREM, OPEN DISK, POLYDISK, SPHERE, UNIT DISK

**Disk Covering Problem**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Given a UNIT DISK, find the smallest RADIUS  $r(n)$  required for  $n$  equal disks to completely cover the UNIT DISK. For a symmetrical arrangement with  $n = 5$  (the FIVE DISKS PROBLEM),  $r(5) = \phi - 1 = 1/\phi = 0.6180340\dots$ , where  $\phi$  is the GOLDEN RATIO. However, the radius can be reduced in the general disk covering problem where symmetry is not required. The first few such values are

$$r(1) = 1$$

$$r(2) = 1$$

$$r(3) = \frac{1}{2}\sqrt{3}$$

$$r(4) = \frac{1}{2}\sqrt{2}$$

$$r(5) = 0.609382864\dots$$

$$r(6) = 0.555$$

$$r(7) = \frac{1}{2}$$

$$r(8) = 0.437$$

$$r(9) = 0.422$$

$$r(10) = 0.398.$$

Here, values for  $n = 6, 8, 9, 10$  were obtained using computer experimentation by Zahn (1962). The value  $r(5)$  is equal to  $\cos(\theta + \phi/2)$ , where  $\theta$  and  $\phi$  are solutions to

$$2 \sin \theta - \sin(\theta + \frac{1}{2}\phi + \psi) - \sin(\psi - \theta - \frac{1}{2}\phi) = 0 \quad (1)$$

$$2 \sin \phi - \sin(\theta + \frac{1}{2}\phi + \chi) - \sin(\chi - \theta - \frac{1}{2}\phi) = 0 \quad (2)$$

$$2 \sin \theta + \sin(\chi + \theta) - \sin(\chi - \theta) - \sin(\psi + \phi) - \sin(\psi - \phi) - 2 \sin(\psi - 2\theta) = 0 \quad (3)$$

$$\cos(2\psi - \chi + \phi) - \cos(2\psi + \chi - \phi) - 2 \cos \chi + \cos(2\psi + \chi - 2\theta) + \cos(2\psi - \chi - 2\theta) = 0 \quad (4)$$

(Neville 1915). It is also given by  $1/x$ , where  $x$  is the largest real root of

$$a(y)x^6 - b(y)x^5 + c(y)x^4 - d(y)x^3 + e(y)x^2 - f(y)x + g(y) = 0 \quad (5)$$

maximized over all  $y$ , subject to the constraints

$$\sqrt{2} < x < 2y + 1 \quad (6)$$

$$-1 < y < 1, \quad (7)$$

and with

$$a(y) = 80y^2 + 64y \quad (8)$$

$$b(y) = 416y^3 + 384y^2 + 64y \quad (9)$$

$$c(y) = 848y^4 + 928y^3 + 352y^2 + 32y \quad (10)$$

$$d(y) = 768y^5 + 992y^4 + 736y^3 + 288y^2 + 96y \quad (11)$$

$$e(y) = 256y^6 + 384y^5 + 592y^4 + 480y^3 + 336y^2 + 96y + 16 \quad (11)$$

$$f(y) = 128y^5 + 192y^4 + 256y^3 + 160y^2 + 96y + 32 \quad (12)$$

$$g(y) = 64y^2 + 64y + 16 \quad (13)$$

(Bezdek 1983, 1984).

Letting  $N(\epsilon)$  be the smallest number of DISKS of RADIUS  $\epsilon$  needed to cover a disk  $D$ , the limit of the ratio of the AREA of  $D$  to the AREA of the disks is given by

$$\lim_{\epsilon \rightarrow 0^+} \frac{1}{\epsilon^2 N(\epsilon)} = \frac{3\sqrt{3}}{2\pi} \quad (14)$$

(Kershner 1939, Verblunsky 1949).

## Disk Lattice Points

see GAUSS'S CIRCLE PROBLEM

## Dispersion Numbers

see MAGIC GEOMETRIC CONSTANTS

## Dispersion Relation

Any pair of equations giving the REAL PART of a function as an integral of its IMAGINARY PART and the IMAGINARY PART as an integral of its REAL PART. Dispersion relationships imply causality in physics. Let

$$f(x_0) \equiv u(x_0) + iv(x_0), \quad (1)$$

then

$$u(x_0) = \frac{1}{\pi} PV \int_{-\infty}^{\infty} \frac{v(x) dx}{x - x_0} \quad (2)$$

$$v(x_0) = -\frac{1}{\pi} PV \int_{-\infty}^{\infty} \frac{u(x) dx}{x - x_0}, \quad (3)$$

where  $PV$  denotes the CAUCHY PRINCIPAL VALUE and  $u(x_0)$  and  $v(x_0)$  are HILBERT TRANSFORMS of each other. If the COMPLEX function is symmetric such that  $f(-x) = f^*(x)$ , then

$$u(x_0) = \frac{2}{\pi} PV \int_0^{\infty} \frac{xv(x) dx}{x^2 - x_0^2} \quad (4)$$

$$v(x_0) = -\frac{2}{\pi} PV \int_0^{\infty} \frac{xu(x) dx}{x^2 - x_0^2}. \quad (5)$$

## Dispersion (Sequence)

An array  $B = b_{ij}$ ,  $i, j \geq 1$  of POSITIVE INTEGERS is called a dispersion if

1. The first column of  $B$  is a strictly increasing sequence, and there exists a strictly increasing sequence  $\{s_k\}$  such that
2.  $b_{12} = s_1 \geq 2$ ,
3. The complement of the SET  $\{b_{1i} : i \geq 1\}$  is the SET  $\{s_k\}$ ,
4.  $b_{ij} = s_{b_{i,j-1}}$  for all  $j \geq 3$  for  $i = 1$  and for all  $g \geq 2$  for all  $i \geq 2$ .

If an array  $B = b_{ij}$  is a dispersion, then it is an INTERSPERSION.

### Disphenocingulum

see JOHNSON SOLID

### Disphenoid

A TETRAHEDRON with identical ISOSCELES or SCALENE faces.

### Dissection

Any two rectilinear figures with equal AREA can be dissected into a finite number of pieces to form each other. This is the WALLACE-BOLYAI-GERWEIN THEOREM. For minimal dissections of a TRIANGLE, PENTAGON, and OCTAGON into a SQUARE, see Stewart (1987, pp. 169–170) and Ball and Coxeter (1987, pp. 89–91). The TRIANGLE to SQUARE dissection (HABERDASHER'S PROBLEM) is particularly interesting because it can be built from hinged pieces which can be folded and unfolded to yield the two shapes (Gardner 1961; Stewart 1987, p. 169; Pappas 1989).

Laczkovich (1988) proved that the CIRCLE can be squared in a finite number of dissections ( $\sim 10^{50}$ ). Furthermore, any shape whose boundary is composed of smoothly curving pieces can be dissected into a SQUARE.

The situation becomes considerably more difficult moving from 2-D to 3-D. In general, a POLYHEDRON cannot be dissected into other POLYHEDRA of a specified type. A CUBE can be dissected into  $n^3$  CUBES, where  $n$  is any INTEGER. In 1900, Dehn proved that not every PRISM cannot be dissected into a TETRAHEDRON (Lenhard 1962, Ball and Coxeter 1987) The third of HILBERT'S PROBLEMS asks for the determination of two TETRAHEDRA which cannot be decomposed into congruent TETRAHEDRA directly or by adjoining congruent TETRAHEDRA. Max Dehn showed this could not be done in 1902, and W. F. Kagon obtained the same result independently in 1903. A quantity growing out of Dehn's work which can be used to analyze the possibility of performing a given solid dissection is the DEHN INVARIANT.

The table below is an updated version of the one given in Gardner (1991, p. 50). Many of the improvements are due to G. Theobald (Frederickson 1997). The minimum number of pieces known to dissect a regular  $n$ -gon (where  $n$  is a number in the first column) into a  $k$ -gon (where  $k$  is a number in the bottom row) is read off by the intersection of the corresponding row and column. In the table,  $\{n\}$  denotes a regular  $n$ -gon, GR a GOLDEN RECTANGLE, GC a GREEK CROSS, LC a LATIN CROSS, MC a MALTESE CROSS, SW a SWASTIKA,  $\{5/2\}$  a five-point star (solid PENTAGRAM),  $\{6/2\}$  a six-point star (i.e., HEXAGRAM or solid STAR OF DAVID), and  $\{8/3\}$  the solid OCTAGRAM.

#### Dissection Puzzles

A puzzle in which one object is to be converted to another by making a finite number of cuts and reassembling it. The cuts are often, but not always, restricted to straight lines. Sometimes, a given puzzle is pre-cut and is to be re-assembled into two or more given shapes.

see also CUNDY AND ROLLETT'S EGG, PYTHAGOREAN SQUARE PUZZLE, T-PUZZLE, TANGRAM

#### Dissipative System

A system in which the phase space volume contracts along a trajectory. This means that the generalized DIVERGENCE is less than zero,

$$\frac{\partial f_i}{\partial x_i} < 0,$$

where EINSTEIN SUMMATION has been used.

#### Distance

Let  $\gamma(t)$  be a smooth curve in a MANIFOLD  $M$  from  $x$  to  $y$  with  $\gamma(0) = x$  and  $\gamma(1) = y$ . Then  $\gamma'(t) \in T_{\gamma(t)}$ , where

$T_x$  is the TANGENT SPACE of  $M$  at  $x$ . The LENGTH of  $\gamma$  with respect to the Riemannian structure is given by

$$\int_0^1 \|\gamma'(t)\|_{\gamma(t)} dt, \quad (1)$$

and the distance  $d(x, y)$  between  $x$  and  $y$  is the shortest distance between  $x$  and  $y$  given by

$$d(x, y) = \inf_{\gamma: x \text{ to } y} \int \|\gamma'(t)\|_{\gamma(t)} dt. \quad (2)$$

In order to specify the relative distances of  $n > 1$  points in the plane,  $1+2(n-2) = 2n-3$  coordinates are needed, since the first can always be taken as  $(0, 0)$  and the second as  $(x, 0)$ , which defines the  $x$ -AXIS. The remaining  $n-2$  points need two coordinates each. However, the total number of distances is

$$\binom{n}{2} = \frac{n!}{2!(n-2)!} = \frac{1}{2}n(n-1), \quad (3)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. The distances between  $n > 1$  points are therefore subject to  $m$  relationships, where

$$m \equiv \frac{1}{2}n(n-1) - (2n-3) = \frac{1}{2}(n-2)(n-3). \quad (4)$$

For  $n = 1, 2, \dots$ , this gives 0, 0, 0, 1, 3, 6, 10, 15, 21, 28, ... (Sloane's A000217) relationships, and the number of relationships between  $n$  points is the TRIANGULAR NUMBER  $T_{n-3}$ .

Although there are no relationships for  $n = 2$  and  $n = 3$  points, for  $n = 4$  (a QUADRILATERAL), there is one (Weinberg 1972):

$$\begin{aligned} 0 = & d_{12}^4 d_{34}^2 + d_{13}^4 d_{24}^2 + d_{14}^4 d_{23}^2 + d_{23}^4 d_{14}^2 \\ & + d_{24}^4 d_{13}^2 + d_{34}^4 d_{12}^2 \\ & + d_{12}^2 d_{23}^2 d_{31}^2 + d_{12}^2 d_{24}^2 d_{41}^2 + d_{13}^2 d_{34}^2 d_{41}^2 \\ & + d_{23}^2 d_{34}^2 d_{42}^2 - d_{12}^2 d_{23}^2 d_{34}^2 - d_{13}^2 d_{32}^2 d_{24}^2 \\ & - d_{12}^2 d_{24}^2 d_{43}^2 - d_{14}^2 d_{42}^2 d_{23}^2 - d_{13}^2 d_{34}^2 d_{42}^2 \\ & - d_{14}^2 d_{43}^2 d_{32}^2 - d_{23}^2 d_{31}^2 d_{14}^2 - d_{21}^2 d_{13}^2 d_{34}^2 \\ & - d_{24}^2 d_{41}^2 d_{13}^2 - d_{21}^2 d_{14}^2 d_{43}^2 - d_{31}^2 d_{12}^2 d_{24}^2 \\ & - d_{32}^2 d_{21}^2 d_{14}^2. \end{aligned} \quad (5)$$

This equation can be derived by writing

$$d_{ij} \equiv \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \quad (6)$$

and eliminating  $x_i$  and  $y_j$  from the equations for  $d_{12}$ ,  $d_{13}$ ,  $d_{14}$ ,  $d_{23}$ ,  $d_{24}$ , and  $d_{34}$ .

#### Distinct Prime Factors

The number of distinct prime factors of a number  $n$  is denoted  $\omega(n)$ . The first few values for  $n = 1, 2, \dots$  are 0, 1, 1, 1, 1, 2, 1, 1, 1, 2, 1, 2, 1, 2, 2, 1, 1, 2, 1, 2, ... (Sloane's A001221). The first few values of the SUMMATORY FUNCTION

$$\sum_{k=2}^n \omega(k)$$

are 1, 2, 3, 4, 6, 7, 8, 9, 11, 12, 14, 15, 17, 19, 20, 21, ... (Sloane's A013939), and the asymptotic value is

$$\sum_{k=2}^n \omega(k) = n \ln \ln n + B_1 n + o(n),$$

where  $B_1$  is MERTENS CONSTANT. In addition,

$$\sum_{k=2}^n [\omega(k)]^2 = n(\ln \ln n)^2 + \mathcal{O}(n \ln \ln n).$$

### Distribution

The distribution of a variable is a description of the relative numbers of times each possible outcome will occur in a number of trials. The function describing the distribution is called the PROBABILITY FUNCTION, and the function describing the probability that a given value or any value smaller than it will occur is called the DISTRIBUTION FUNCTION.

Formally, a distribution can be defined as a normalized MEASURE, and the distribution of a RANDOM VARIABLE  $x$  is the MEASURE  $P_x$  on  $S'$  defined by setting

$$P_x(A') = P\{s \in S : x(s) \in A'\},$$

where  $(S, \mathbb{S}, P)$  is a PROBABILITY SPACE,  $(S, \mathbb{S})$  is a MEASURABLE SPACE, and  $P$  a MEASURE on  $\mathbb{S}$  with  $P(S) = 1$ .

see also CONTINUOUS DISTRIBUTION, DISCRETE DISTRIBUTION, DISTRIBUTION FUNCTION, MEASURABLE SPACE, MEASURE, PROBABILITY, PROBABILITY DENSITY FUNCTION, RANDOM VARIABLE, STATISTICS

### References

Doob, J. L. "The Development of Rigor in Mathematical Probability (1900–1950)." *Amer. Math. Monthly* **103**, 586–595, 1996.

### Distribution Function

The distribution function  $D(x)$ , sometimes also called the PROBABILITY DISTRIBUTION FUNCTION, describes the probability that a trial  $X$  takes on a value less than or equal to a number  $x$ . The distribution function is therefore related to a continuous PROBABILITY DENSITY FUNCTION  $P(x)$  by

$$D(x) = P(X \leq x) \equiv \int_{-\infty}^x P(x') dx', \quad (1)$$

so  $P(x)$  (when it exists), is simply the derivative of the distribution function

$$P(x) = D'(x) = [P(x')]_{-\infty}^x = P(x) - P(-\infty). \quad (2)$$

Similarly, the distribution function is related to a discrete probability  $P(x)$  by

$$D(x) = P(X \leq x) = \sum_{X \leq x} P(x). \quad (3)$$

In general, there exist distributions which are neither continuous nor discrete.

A JOINT DISTRIBUTION FUNCTION can be defined if outcomes are dependent on two parameters:

$$D(x, y) \equiv P(X \leq x, Y \leq y) \quad (4)$$

$$D_x(x) \equiv D(x, \infty) \quad (5)$$

$$D_y(y) \equiv D(\infty, y). \quad (6)$$

Similarly, a multiple distribution function can be defined if outcomes depend on  $n$  parameters:

$$D(a_1, \dots, a_n) \equiv P(x_1 \leq a_1, \dots, x_n \leq a_n). \quad (7)$$

Given a continuous  $P(x)$ , assume you wish to generate numbers distributed as  $P(x)$  using a random number generator. If the random number generator yields a uniformly distributed value  $y_i$  in  $[0, 1]$  for each trial  $i$ , then compute

$$D(x) \equiv \int_{-\infty}^x P(x') dx'. \quad (8)$$

The FORMULA connecting  $y_i$  with a variable distributed as  $P(x)$  is then

$$x_i = D^{-1}(y_i), \quad (9)$$

where  $D^{-1}(x)$  is the inverse function of  $D(x)$ . For example, if  $P(x)$  were a GAUSSIAN DISTRIBUTION so that

$$D(x) = \frac{1}{2} \left[ 1 + \operatorname{erf} \left( \frac{x - \mu}{\sigma\sqrt{2}} \right) \right], \quad (10)$$

then

$$x_i = \sigma\sqrt{2} \operatorname{erf}^{-1}(2y_i - 1) + \mu. \quad (11)$$

If  $P(x) = Cx^n$  for  $x \in (x_{\min}, x_{\max})$ , then normalization gives

$$\int_{x_{\min}}^{x_{\max}} P(x) dx = C \frac{[x^{n+1}]_{x_{\min}}^{x_{\max}}}{n+1} = 1, \quad (12)$$

so

$$C = \frac{n+1}{x_{\max}^{n+1} - x_{\min}^{n+1}}. \quad (13)$$

Let  $y$  be a uniformly distributed variate on  $[0, 1]$ . Then

$$\begin{aligned} D(x) &= \int_{x_{\min}}^x P(x) dx = C \int_{x_{\min}}^x x^n dx \\ &= \frac{C}{n+1} (x^{n+1} - x_{\min}^{n+1}) \equiv y, \end{aligned} \quad (14)$$

and the variate given by

$$\begin{aligned} x &= \left( \frac{n+1}{C} y + x_{\min}^{n+1} \right)^{1/(n+1)} \\ &= [(x_{\max}^{n+1} - x_{\min}^{n+1})y + x_{\min}^{n+1}]^{1/(n+1)} \end{aligned} \quad (15)$$

is distributed as  $P(x)$ .

A distribution with constant VARIANCE of  $y$  for all values of  $x$  is known as a HOMOSCEDASTIC distribution. The method of finding the value at which the distribution is a maximum is known as the MAXIMUM LIKELIHOOD method.

### Distribution (Functional)

A functional distribution, also called a GENERALIZED FUNCTION, is a generalization of the concept of a function. Functional distributions are defined as continuous linear FUNCTIONALS over a SPACE of infinitely differentiable functions such that all continuous functions have SCHWARZIAN DERIVATIVES which are themselves distributions. The most commonly encountered functional distribution is the DELTA FUNCTION.

see also DELTA FUNCTION, GENERALIZED FUNCTION, SCHWARZIAN DERIVATIVE

### Distribution Parameter

The distribution parameter of a NONCYLINDRICAL RULED SURFACE parameterized by

$$\mathbf{x}(u, v) = \boldsymbol{\sigma}(u) + v\boldsymbol{\delta}(u), \quad (1)$$

where  $\boldsymbol{\sigma}$  is the STRICTION CURVE and  $\boldsymbol{\delta}$  the DIRECTOR CURVE, is the function  $p$  defined by

$$p = \frac{\det(\boldsymbol{\sigma}'\boldsymbol{\delta}\boldsymbol{\delta}')}{\boldsymbol{\delta}' \cdot \boldsymbol{\delta}'} \quad (2)$$

The GAUSSIAN CURVATURE of a RULED SURFACE is given in terms of its distribution parameter by

$$K = -\frac{[p(u)]^2}{\{[p(u)]^2 + v^2\}^2} \quad (3)$$

see also NONCYLINDRICAL RULED SURFACE, STRICTION CURVE

### Distribution (Statistical)

The set of probabilities for each possible event.

see DISTRIBUTION FUNCTION

### Distributive

Elements of an ALGEBRA which obey the identity

$$A(B + C) = AB + AC$$

are said to be distributive over the operation  $+$ .

see also ASSOCIATIVE, COMMUTATIVE, TRANSITIVE

**Distributive Lattice**

A LATTICE which satisfies the identities

$$(x \wedge y) \vee (x \wedge z) = x \wedge (y \vee z)$$

$$(x \vee y) \wedge (x \vee z) = x \vee (y \wedge z)$$

is said to be distributive.

see also LATTICE, MODULAR LATTICE

**References**

Grätzer, G. *Lattice Theory: First Concepts and Distributive Lattices*. San Francisco, CA: W. H. Freeman, pp. 35–36, 1971.

**Disymmetric**

An object which is not superimposable on its MIRROR IMAGE is said to be disymmetric. All asymmetric objects are disymmetric, and an object with no IMPROPER ROTATION (rotoinversion) axis must also be disymmetric.

**Ditrigonal Dodecadodecahedron**

The UNIFORM POLYHEDRON  $U_{41}$ , also called the DITRIGONAL DODECAHEDRON, whose DUAL POLYHEDRON is the MEDIAL TRIAMBIC ICOSAEDRON. It has WYTHOFF SYMBOL  $3 | \frac{5}{3} 5$ . Its faces are  $12\{\frac{5}{2}\} + 12\{5\}$ . It is a FACETED version of the SMALL DITRIGONAL ICOSIDODECAHEDRON. The CIRCUMRADIUS for unit edge length is

$$R = \frac{1}{2}\sqrt{3}.$$

**References**

Wenninger, M. J. *Polyhedron Models*. Cambridge, England: Cambridge University Press, pp. 123–124, 1989.

**Ditrigonal Dodecahedron**

see DITRIGONAL DODECADODECAHEDRON

**Divergence**

The divergence of a VECTOR FIELD  $\mathbf{F}$  is given by

$$\text{div}(\mathbf{F}) \equiv \nabla \cdot \mathbf{F} \equiv \lim_{V \rightarrow 0} \frac{\oint_S \mathbf{F} \cdot d\mathbf{a}}{V}. \quad (1)$$

Define

$$\mathbf{F} \equiv F_1 \hat{\mathbf{u}}_1 + F_2 \hat{\mathbf{u}}_2 + F_3 \hat{\mathbf{u}}_3. \quad (2)$$

Then in arbitrary orthogonal CURVILINEAR COORDINATES,

$$\text{div}(\mathbf{F}) \equiv \nabla \cdot \mathbf{F} \equiv \frac{1}{h_1 h_2 h_3} \left[ \frac{\partial}{\partial u_1} (h_2 h_3 F_1) + \frac{\partial}{\partial u_2} (h_3 h_1 F_2) + \frac{\partial}{\partial u_3} (h_1 h_2 F_3) \right]. \quad (3)$$

If  $\nabla \cdot \mathbf{F} = 0$ , then the field is said to be a DIVERGENCE-LESS FIELD. For divergence in individual coordinate systems, see CURVILINEAR COORDINATES.

$$\nabla \cdot \frac{\mathbf{Ax}}{|\mathbf{x}|} = \frac{\text{Tr}(\mathbf{A})}{|\mathbf{x}|} - \frac{\mathbf{x}^T (\mathbf{Ax})}{|\mathbf{x}|^3}. \quad (4)$$

The divergence of a TENSOR  $A$  is

$$\nabla \cdot A \equiv A_{;\alpha}^\alpha = A_{,k}^k + \Gamma_{jk}^k A^j, \quad (5)$$

where ; is the COVARIANT DERIVATIVE. Expanding the terms gives

$$\begin{aligned} A_{;\alpha}^\alpha &= A_{,\alpha}^\alpha + (\Gamma_{\alpha\alpha}^\alpha A^\alpha + \Gamma_{\beta\alpha}^\alpha A^\beta + \Gamma_{\gamma\alpha}^\alpha A^\gamma) \\ &+ A_{,\beta}^\beta + (\Gamma_{\alpha\beta}^\beta A^\alpha + \Gamma_{\beta\beta}^\beta A^\beta + \Gamma_{\gamma\beta}^\beta A^\gamma) \\ &+ A_{,\gamma}^\gamma + (\Gamma_{\alpha\gamma}^\gamma A^\alpha + \Gamma_{\beta\gamma}^\gamma A^\beta + \Gamma_{\gamma\gamma}^\gamma A^\gamma). \end{aligned} \quad (6)$$

see also CURL, CURL THEOREM, GRADIENT, GREEN'S THEOREM, DIVERGENCE THEOREM, VECTOR DERIVATIVE

**References**

Arfken, G. "Divergence,  $\nabla \cdot$ ." §1.7 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 37–42, 1985.

**Divergence Tests**

If

$$\lim_{k \rightarrow \infty} u_k \neq 0,$$

then the series  $\{u_n\}$  diverges.

see also CONVERGENCE TESTS, CONVERGENT SERIES, DINI'S TEST, SERIES

**Divergence Theorem**

A.k.a. GAUSS'S THEOREM. Let  $V$  be a region in space with boundary  $\partial V$ . Then

$$\int_V (\nabla \cdot \mathbf{F}) dV = \int_{\partial V} \mathbf{F} \cdot d\mathbf{a}. \quad (1)$$

Let  $S$  be a region in the plane with boundary  $\partial S$ .

$$\int_S \nabla \cdot \mathbf{F} dA = \int_{\partial S} \mathbf{F} \cdot \mathbf{n} ds. \quad (2)$$

If the VECTOR FIELD  $\mathbf{F}$  satisfies certain constraints, simplified forms can be used. If  $\mathbf{F}(x, y, z) = v(x, y, z)\mathbf{c}$  where  $\mathbf{c}$  is a constant vector  $\neq \mathbf{0}$ , then

$$\int_S \mathbf{F} \cdot d\mathbf{a} = \mathbf{c} \cdot \int_S v d\mathbf{a}. \quad (3)$$

But

$$\nabla \cdot (f\mathbf{v}) = (\nabla f) \cdot \mathbf{v} + f(\nabla \cdot \mathbf{v}), \quad (4)$$

so

$$\int_V \nabla \cdot (c\mathbf{v}) dV = \mathbf{c} \cdot \int_V (\nabla \mathbf{v} + \mathbf{v} \nabla \cdot \mathbf{c}) dV = \mathbf{c} \cdot \int_V \nabla \mathbf{v} dV \quad (5)$$

$$\mathbf{c} \cdot \left( \int_S v d\mathbf{a} - \int_V \nabla v dV \right) = 0. \quad (6)$$

But  $\mathbf{c} \neq \mathbf{0}$ , and  $\mathbf{c} \cdot \mathbf{f}(v)$  must vary with  $v$  so that  $\mathbf{c} \cdot \mathbf{f}(v)$  cannot always equal zero. Therefore,

$$\int_S v d\mathbf{a} = \int_V \nabla v dV. \quad (7)$$

If  $\mathbf{F}(x, y, z) = \mathbf{c} \times P(x, y, z)$ , where  $\mathbf{c}$  is a constant vector  $\neq \mathbf{0}$ , then

$$\int_S d\mathbf{a} \times \mathbf{P} = \int_V \nabla \times \mathbf{P} dV. \quad (8)$$

see also CURL THEOREM, GRADIENT, GREEN'S THEOREM

### Divergenceless Field

A divergenceless field, also called a SOLENOIDAL FIELD, is a FIELD for which  $\nabla \cdot \mathbf{F} = \mathbf{0}$ . Therefore, there exists a  $\mathbf{G}$  such that  $\mathbf{F} = \nabla \times \mathbf{G}$ . Furthermore,  $\mathbf{F}$  can be written as

$$\mathbf{F} = \nabla \times (T\mathbf{r}) + \nabla^2(S\mathbf{r}) \equiv \mathbf{T} + \mathbf{S},$$

where

$$\begin{aligned} \mathbf{T} &\equiv \nabla \times (T\mathbf{r}) = -\mathbf{r} \times (\nabla T) \\ \mathbf{S} &\equiv \nabla^2(S\mathbf{r}) = \nabla \left[ \frac{\partial}{\partial r}(rS) \right] - \mathbf{r} \nabla^2 S. \end{aligned}$$

Following Lamb,  $\mathbf{T}$  and  $\mathbf{S}$  are called TOROIDAL FIELD and POLOIDAL FIELD.

see also BELTRAMI FIELD, IRROTATIONAL FIELD, POLOIDAL FIELD, SOLENOIDAL FIELD, TOROIDAL FIELD

### Divergent Sequence

A divergent sequence is a SEQUENCE for which the LIMIT exists but is not CONVERGENT.

see also CONVERGENT SEQUENCE, DIVERGENT SERIES

### Divergent Series

A SERIES which is not CONVERGENT. Series may diverge by marching off to infinity or by oscillating.

see also CONVERGENT SERIES, DIVERGENT SEQUENCE

### Diversity Condition

For any group of  $k$  men out of  $N$ , there must be at least  $k$  jobs for which they are collectively qualified.

### Divide

To divide is to perform the operation of DIVISION, i.e., to see how many time a DIVISOR  $d$  goes into another number  $n$ .  $n$  divided by  $d$  is written  $n/d$  or  $n \div d$ . The result need not be an INTEGER, but if it is, some additional terminology is used.  $d|n$  is read " $d$  divides  $n$ " and means that  $d$  is a PROPER DIVISOR of  $n$ . In this case,  $n$  is said to be DIVISIBLE by  $d$ . Clearly,  $1|n$  and  $n|n$ . By convention,  $n|0$  for every  $n$  except 0 (Hardy and Wright 1979). The "divided" operation satisfies

$$\begin{aligned} b|a \text{ and } c|b &\Rightarrow c|a \\ b|a &\Rightarrow bc|ac \\ c|a \text{ and } c|b &\Rightarrow c|(ma + nb). \end{aligned}$$

$d'|n$  is read " $d'$  does not divide  $n$ " and means that  $d'$  is not a PROPER DIVISOR of  $n$ .  $a^k||b$  means  $a^k$  divides  $b$  exactly.

### Divided Difference

The divided difference  $f[x_1, x_2, \dots, x_n]$  on  $n$  points  $x_1, x_2, \dots, x_n$  of a function  $f(x)$  is defined by  $f[x_1] \equiv f(x_1)$  and

$$f[x_1, x_2, \dots, x_n] = \frac{f[x_1, \dots, x_n] - f[x_2, \dots, x_n]}{x_1 - x_n} \quad (1)$$

for  $n \geq 2$ . The first few differences are

$$[x_0, x_1] = \frac{f_0 - f_1}{x_0 - x_1} \quad (2)$$

$$[x_0, x_1, x_2] = \frac{[x_0, x_1] - [x_1, x_2]}{x_0 - x_2} \quad (3)$$

$$[x_0, x_1, \dots, x_n] = \frac{[x_0, \dots, x_{n-1}] - [x_1, \dots, x_n]}{x_0 - x_n}. \quad (4)$$

Defining

$$\pi_n(x) \equiv (x - x_0)(x - x_1) \cdots (x - x_n) \quad (5)$$

and taking the DERIVATIVE

$$\pi'_n(x_k) = (x_k - x_0) \cdots (x_k - x_{k-1})(x_k - x_{k+1}) \cdots (x_k - x_n) \quad (6)$$

gives the identity

$$[x_0, x_1, \dots, x_n] = \sum_{k=0}^n \frac{f_k}{\pi'_n(x_k)}. \quad (7)$$

Consider the following question: does the property

$$f[x_1, x_2, \dots, x_n] = h(x_1 + x_2 + \dots + x_n) \quad (8)$$

for  $n \geq 2$  and  $h(x)$  a given function guarantee that  $f(x)$  is a POLYNOMIAL of degree  $\leq n$ ? Aczél (1985) showed that the answer is “yes” for  $n = 2$ , and Bailey (1992) showed it to be true for  $n = 3$  with differentiable  $f(x)$ . Schwaiger (1994) and Andersen (1996) subsequently showed the answer to be “yes” for all  $n \geq 3$  with restrictions on  $f(x)$  or  $h(x)$ .

## Divisibility Tests

Write a decimal number  $a$  out digit by digit in the form  $a_n \dots a_3 a_2 a_1 a_0$ . It is always true that  $10^0 = 1 \equiv 1$  for any base.

- 2  $10^1 \equiv 0$ , so  $10^n \equiv 0$  for  $n \geq 1$ . Therefore, if the last digit  $a_0$  is divisible by 2 (i.e., is EVEN), then so is  $a$ .
- 3  $10^1 \equiv 1$ ,  $10^2 \equiv 1$ ,  $\dots$ ,  $10^n \equiv 1$ . Therefore, if  $\sum_{i=1}^n a_i$  is divisible by 3, so is  $a$ .
- 4  $10^1 \equiv 2$ ,  $10^2 \equiv 0$ ,  $\dots$ ,  $10^n \equiv 0$ . So if the last two digits are divisible by 4, more specifically if  $r \equiv a_0 + 2a_1$  is, then so is  $a$ .
- 5  $10^1 \equiv 0$ , so  $10^n \equiv 0$  for  $n \geq 1$ . Therefore, if the last digit  $a_0$  is divisible by 5 (i.e., is 5 or 0), then so is  $a$ .
- 6  $10^1 \equiv -2$ ,  $10^2 \equiv -2$ , so  $10^n \equiv -2$ . Therefore, if  $r \equiv a_0 - 2 \sum_{i=1}^n a_i$  is divisible by 6, so is  $a$ . If  $a$  is divisible by 3 and is EVEN, it is also divisible by 6.
- 7  $10^1 \equiv 3$ ,  $10^2 \equiv 2$ ,  $10^3 \equiv -1$ ,  $10^4 \equiv -3$ ,  $10^5 \equiv -2$ ,  $10^6 \equiv 1$ , and the sequence then repeats. Therefore, if  $r \equiv (a_0 + 3a_1 + 2a_2 - a_3 - 3a_4 - 2a_5) + (a_6 + 3a_7 + \dots) + \dots$  is divisible by 7, so is  $a$ .

8  $10^1 \equiv 2$ ,  $10^2 \equiv 4$ ,  $10^3 \equiv 0$ ,  $\dots$ ,  $10^n \equiv 0$ . Therefore, if the last three digits are divisible by 8, more specifically if  $r \equiv a_0 + 2a_1 + 4a_2$  is, then so is  $a$ .

9  $10^1 \equiv 1$ ,  $10^2 \equiv 1$ ,  $\dots$ ,  $10^3 \equiv 1$ . Therefore, if  $\sum_{i=1}^n a_i$  is divisible by 9, so is  $a$ .

10  $10^1 \equiv 0$ , so if the last digit is 0, then  $a$  is divisible by 10.

11  $10^1 \equiv -1$ ,  $10^2 \equiv 1$ ,  $10^3 \equiv -1$ ,  $10^4 \equiv 1$ ,  $\dots$ . Therefore, if  $r \equiv a_0 - a_1 + a_2 - a_3 + \dots$  is divisible by 11, then so is  $a$ .

12  $10^1 \equiv -2$ ,  $10^2 \equiv 4$ ,  $10^3 \equiv 4$ ,  $\dots$ . Therefore, if  $r \equiv a_0 - 2a_1 + 4(a_2 + a_3 + \dots)$  is divisible by 12, then so is  $a$ . Divisibility by 12 can also be checked by seeing if  $a$  is divisible by 3 and 4.

13  $10^1 \equiv -3$ ,  $10^2 \equiv -4$ ,  $10^3 \equiv -1$ ,  $10^4 \equiv 3$ ,  $10^5 \equiv 4$ ,  $10^6 \equiv 1$ , and the pattern repeats. Therefore, if  $r \equiv (a_0 - 3a_1 - 4a_2 - a_3 + 3a_4 + 4a_5) + (a_6 - 3a_7 + \dots) + \dots$  is divisible by 13, so is  $a$ .

For additional tests for 13, see Gardner (1991).

## Divisible

A number  $n$  is said to be divisible by  $d$  if  $d$  is a PROPER DIVISOR of  $n$ . The sum of any  $n$  consecutive INTEGERS is divisible by  $n!$ , where  $n!$  is the FACTORIAL.

see also DIVIDE, DIVISOR, DIVISOR FUNCTION

### References

## Division

Taking the RATIO  $x/y$  of two numbers  $x$  and  $y$ , also written  $x \div y$ . Here,  $y$  is called the DIVISOR. The symbol “/” is called a SOLIDUS (or DIAGONAL), and the symbol “÷” is called the OBELUS. Division in which the fractional (remainder) is discarded is called INTEGER DIVISION, and is sometimes denoted using a backslash, \.

see also ADDITION, DIVIDE, INTEGER DIVISION, LONG DIVISION, MULTIPLICATION, OBELUS, ODDS, RATIO, SKELETON DIVISION, SOLIDUS, SUBTRACTION, TRIAL DIVISION

## Division Algebra

A division algebra, also called a DIVISION RING or SKEW FIELD, is a RING in which every NONZERO element has a multiplicative inverse, but multiplication is not COMMUTATIVE. Explicitly, a division algebra is a set together with two BINARY OPERATORS  $S(+, *)$  satisfying the following conditions:

1. Additive associativity: For all  $a, b, c \in S$ ,  $(a+b)+c = a+(b+c)$ ,
2. Additive commutativity: For all  $a, b \in S$ ,  $a+b = b+a$ ,
3. Additive identity: There exists an element  $0 \in S$  such that for all  $a \in S$ ,  $0+a = a+0 = a$ ,
4. Additive inverse: For every  $a \in S$  there exists a  $-a \in S$  such that  $a+(-a) = (-a)+a = 0$ ,
5. Multiplicative associativity: For all  $a, b, c \in S$ ,  $(a*b)*c = a*(b*c)$ ,
6. Multiplicative identity: There exists an element  $1 \in S$  not equal to 0 such that for all  $a \in S$ ,  $1*a = a*1 = a$ ,
7. Multiplicative inverse: For every  $a \in S$  not equal to 0, there exists  $a^{-1} \in S$ ,  $a*a^{-1} = a^{-1}*a = 1$ ,
8. Left and right distributivity: For all  $a, b, c \in S$ ,  $a*(b+c) = (a*b)+(a*c)$  and  $(b+c)*a = (b*a)+(c*a)$ .

Thus a division algebra  $(S, +, *)$  is a UNIT RING for which  $(S - \{0\}, *)$  is a GROUP. A division algebra must contain at least two elements. A COMMUTATIVE division algebra is called a FIELD.

In 1878 and 1880, Frobenius and Peirce proved that the only associative REAL division algebras are real numbers, COMPLEX NUMBERS, and QUATERNIONS. The CAYLEY ALGEBRA is the only NONASSOCIATIVE DIVISION ALGEBRA. Hurwitz (1898) proved that the ALGEBRAS of REAL NUMBERS, COMPLEX NUMBERS, QUATERNIONS, and CAYLEY NUMBERS are the only ones where multiplication by unit "vectors" is distance-preserving. Adams (1956) proved that  $n$ -D vectors form an ALGEBRA in which division (except by 0) is always possible only for  $n = 1, 2, 4$ , and 8.

### Division Lemma

When  $ac$  is DIVISIBLE by a number  $b$  that is RELATIVELY PRIME to  $a$ , then  $c$  must be DIVISIBLE by  $b$ .

### Division Ring

see DIVISION ALGEBRA

### Divisor

A divisor of a number  $N$  is a number  $d$  which DIVIDES  $N$ , also called a FACTOR. The total number of divisors for a given number  $N$  can be found as follows. Write a number in terms of its PRIME FACTORIZATION

$$N = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_r^{\alpha_r}. \quad (1)$$

For any divisor  $d$  of  $N$ ,  $N = dd'$  where

$$d = p_1^{\delta_1} p_2^{\delta_2} \cdots p_r^{\delta_r}, \quad (2)$$

so

$$d' = p_1^{\alpha_1 - \delta_1} p_2^{\alpha_2 - \delta_2} \cdots p_r^{\alpha_r - \delta_r}. \quad (3)$$

Now,  $\delta_1 = 0, 1, \dots, \alpha_1$ , so there are  $\alpha_1 + 1$  possible values. Similarly, for  $\delta_n$ , there are  $\alpha_n + 1$  possible values, so the total number of divisors  $\nu(N)$  of  $N$  is given by

$$\nu(N) = \prod_{n=1}^r (\alpha_n + 1). \quad (4)$$

The function  $\nu(N)$  is also sometimes denoted  $d(N)$  or  $\sigma_0(N)$ . The product of divisors can be found by writing the number  $N$  in terms of all possible products

$$N = \begin{pmatrix} d^{(1)} d'^{(1)} \\ \vdots \\ d^{(\nu)} d'^{(\nu)} \end{pmatrix}, \quad (5)$$

so

$$\begin{aligned} N^{\nu(N)} &= [d^{(1)} \cdots d^{(\nu)}] [d'^{(1)} d'^{(\nu)}] \\ &= \prod_{i=1}^{\nu} d_i \prod_{i=1}^{\nu} d'_i = \left( \prod d \right)^2, \end{aligned} \quad (6)$$

and

$$\prod d = N^{\nu(N)/2}. \quad (7)$$

The GEOMETRIC MEAN of divisors is

$$G = \left( \prod d \right)^{\nu(N)/2} = [N^{\nu(N)/2}]^{1/\nu(N)} = \sqrt{N}. \quad (8)$$

The sum of the divisors can be found as follows. Let  $N \equiv ab$  with  $a \neq b$  and  $(a, b) = 1$ . For any divisor  $d$  of  $N$ ,  $d = a_i b_i$ , where  $a_i$  is a divisor of  $a$  and  $b_i$  is a divisor of  $b$ . The divisors of  $a$  are 1,  $a_1, a_2, \dots$ , and  $a$ . The divisors of  $b$  are 1,  $b_1, b_2, \dots$ ,  $b$ . The sums of the divisors are then

$$\sigma(a) = 1 + a_1 + a_2 + \dots + a \quad (9)$$

$$\sigma(b) = 1 + b_1 + b_2 + \dots + b. \quad (10)$$

For a given  $a_i$ ,

$$a_i(1 + b_1 + b_2 + \dots + b) = a_i \sigma(b). \quad (11)$$

Summing over all  $a_i$ ,

$$(1 + a_1 + a_2 + \dots + a) \sigma(b) = \sigma(a) \sigma(b), \quad (12)$$

so  $\sigma(N) = \sigma(ab) = \sigma(a) \sigma(b)$ . Splitting  $a$  and  $b$  into prime factors,

$$\sigma(N) = \sigma(p_1^{\alpha_1}) \sigma(p_2^{\alpha_2}) \dots \sigma(p_r^{\alpha_r}). \quad (13)$$

For a prime POWER  $p_i^{\alpha_i}$ , the divisors are  $1, p_i, p_i^2, \dots, p_i^{\alpha_i}$ , so

$$\sigma(p_i^{\alpha_i}) = 1 + p_i + p_i^2 + \dots + p_i^{\alpha_i} = \frac{p_i^{\alpha_i+1} - 1}{p_i - 1}. \quad (14)$$

For  $N$ , therefore,

$$\sigma(N) = \prod_{i=1}^r \frac{p_i^{\alpha_i+1} - 1}{p_i - 1}. \quad (15)$$

For the special case of  $N$  a PRIME, (15) simplifies to

$$\sigma(p) = \frac{p^2 - 1}{p - 1} = p + 1. \quad (16)$$

For  $N$  a POWER of two, (15) simplifies to

$$\sigma(2^\alpha) = \frac{2^{\alpha+1} - 1}{2 - 1} = 2^{\alpha+1} - 1. \quad (17)$$

The ARITHMETIC MEAN is

$$A(N) \equiv \frac{\sigma(N)}{\nu(N)}. \quad (18)$$

The HARMONIC MEAN is

$$\frac{1}{H} \equiv \frac{1}{n} \left( \sum \frac{1}{d} \right). \quad (19)$$

But  $N = dd'$ , so  $\frac{1}{\nu(N)} = \frac{d'}{N}$  and

$$\sum \frac{1}{d} = \frac{1}{N} \sum d' = \frac{1}{N} \sum d = \frac{\sigma(N)}{N}, \quad (20)$$

and we have

$$\frac{1}{H(N)} = \frac{1}{N(\nu)} \frac{\sigma(N)}{N} = \frac{A(N)}{N} \quad (21)$$

$$N = A(N)H(N). \quad (22)$$

Given three INTEGERS chosen at random, the probability that no common factor will divide them all is

$$[\zeta(3)]^{-1} \approx 1.202^{-1} = 0.832 \dots, \quad (23)$$

where  $\zeta(3)$  is APÉRY'S CONSTANT.

Let  $f(n)$  be the number of elements in the greatest subset of  $[1, n]$  such that none of its elements are divisible by two others. For  $n$  sufficiently large,

$$0.6725 \dots \leq \frac{f(n)}{n} \leq 0.673 \dots \quad (24)$$

(Le Lionnais 1983, Lebensold 1976/1977).

### Divisor Function

$\sigma_k(n)$  is defined as the sum of the  $k$ th POWERS of the DIVISORS of  $n$ . The function  $\sigma_0(n)$  gives the total number of DIVISORS of  $n$  and is often denoted  $d(n)$ ,  $\nu(n)$ ,  $\tau(n)$ , or  $\Omega(n)$  (Hardy and Wright 1979, pp. 354-355). The first few values of  $\sigma_0(n)$  are 1, 2, 2, 3, 2, 4, 2, 4, 3, 4, 2, 6, ... (Sloane's A000005). The function  $\sigma_1(n)$  is equal to the sum of DIVISORS of  $n$  and is often denoted  $\sigma(n)$ . The first few values of  $\sigma(n)$  are 1, 3, 4, 7, 6, 12, 8, 15, 13, 18, ... (Sloane's A000203). The first few values of  $\sigma_2(n)$  are 1, 5, 10, 21, 26, 50, 50, 85, 91, 130, ... (Sloane's A001157). The first few values of  $\sigma_3(n)$  are 1, 9, 28, 73, 126, 252, 344, 585, 757, 1134, ... (Sloane's A001158).

The sum of the DIVISORS of  $n$  excluding  $n$  itself (i.e., the PROPER DIVISORS of  $n$ ) is called the RESTRICTED DIVISOR FUNCTION and is denoted  $s(n)$ . The first few values are 0, 1, 1, 3, 1, 6, 1, 7, 4, 8, 1, 16, ... (Sloane's A001065).

As an illustrative example, consider the number 140, which has DIVISORS  $d_i = 1, 2, 4, 5, 7, 10, 14, 20, 28, 35, 70$ , and 140 (for a total of  $N = 12$  of them). Therefore,

$$d(140) = N = 12 \quad (1)$$

$$\sigma(140) = \sum_i^N d_i = 336 \quad (2)$$

$$\sigma_2(140) = \sum_i^N d_i^2 = 27,300 \quad (3)$$

$$\sigma_3(140) = \sum_i^N d_i^3 = 3,164,112. \quad (4)$$

The  $\sigma(n)$  function has the series expansion

$$\sigma(n) = \frac{1}{6}\pi^2 n \left[ 1 + \frac{(-1)^n}{2^2} + \frac{2\cos(\frac{2}{3}n\pi)}{3^2} + \frac{2\cos(\frac{1}{2}n\pi)}{4^2} + \frac{2[\cos(\frac{2}{5}n\pi) + \cos(\frac{4}{5}n\pi)]}{5^2} + \dots \right] \quad (5)$$

(Hardy 1959). It also satisfies the INEQUALITY

$$\frac{\sigma(n)}{n \ln \ln n} \leq e^\gamma + \frac{2(1 - \sqrt{2}) + \gamma - \ln(4\pi)}{\sqrt{\ln n} \ln \ln n} + \mathcal{O}\left(\frac{1}{\sqrt{\ln n} (\ln \ln n)^2}\right), \quad (6)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT (Robin 1984, Erdős 1989).

Let a number  $n$  have PRIME factorization

$$n = \prod_{j=1}^r p_j^{\alpha_j}, \quad (7)$$

then

$$\sigma(n) = \prod_{j=1}^r \frac{p_j^{\alpha_j+1} - 1}{p_j - 1} \quad (8)$$

(Berndt 1985). GRONWALL'S THEOREM states that

$$\lim_{n \rightarrow \infty} \frac{\sigma(n)}{n \ln \ln n} = e^\gamma, \quad (9)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT.

In general,

$$\sigma_k(n) \equiv \sum_{d|n} d^k. \quad (10)$$

In 1838, Dirichlet showed that the average number of DIVISORS of all numbers from 1 to  $n$  is asymptotic to

$$\frac{\sum_{i=1}^n \sigma_0(i)}{n} \sim \ln n + 2\gamma - 1 \quad (11)$$

(Conway and Guy 1996), as illustrated above, where the thin solid curve plots the actual values and the thick dashed curve plots the asymptotic function.

A curious identity derived using MODULAR FORM theory is given by

$$\sigma_7(n) = \sigma_3(n) + 120 \sum_{k=1}^{n-1} \sigma_3(k) \sigma_3(n-k). \quad (12)$$

The asymptotic SUMMATORY FUNCTION of  $\sigma_0(n) = \Omega(n)$  is given by

$$\sum_{k=2}^n \Omega(k) = n \ln \ln n + B_2 + o(n), \quad (13)$$

where

$$B_2 = \gamma + \sum_{p \text{ prime}} \left[ \ln(1 - p^{-1}) + \frac{1}{p-1} \right] \approx 1.034653 \quad (14)$$

(Hardy and Wright 1979, p. 355). This is related to the DIRICHLET DIVISOR PROBLEM. The SUMMATORY FUNCTIONS for  $\sigma_a$  with  $a > 1$  are

$$\sum_{k=1}^n \sigma_a(k) = \frac{\zeta(a+1)}{a+1} n^{a+1} + \mathcal{O}(n^a). \quad (15)$$

For  $a = 1$ ,

$$\sum_{k=1}^n \sigma_1(k) = \frac{\pi^2}{12} n^2 + \mathcal{O}(n \ln n). \quad (16)$$

The divisor function is ODD IFF  $n$  is a SQUARE NUMBER or twice a SQUARE NUMBER. The divisor function satisfies the CONGRUENCE

$$n\sigma(n) \equiv 2 \pmod{\phi(n)}, \quad (17)$$

for all PRIMES and no COMPOSITE NUMBERS with the exception of 4, 6, and 22 (Subbarao 1974).  $\tau(n)$  is PRIME whenever  $\sigma(n)$  is (Honsberger 1991). Factorizations of  $\sigma(p^a)$  for PRIME  $p$  are given by Sorli.

## Divisor Theory

A generalization by Kronecker of Kummer's theory of PRIME IDEAL factors. A divisor on a full subcategory  $C$  of  $\text{mod}(A)$  is an additive mapping  $\chi$  on  $C$  with values in a SEMIGROUP of IDEALS on  $A$ .

## Dixon's Factorization Method

In order to find INTEGERS  $x$  and  $y$  such that

$$x^2 \equiv y^2 \pmod{n} \quad (1)$$

(a modified form of FERMAT'S FACTORIZATION METHOD), in which case there is a 50% chance that  $\text{GCD}(n, x - y)$  is a FACTOR of  $n$ , choose a RANDOM INTEGER  $r_i$ , compute

$$g(r_i) \equiv r_i^2 \pmod{n}, \quad (2)$$

and try to factor  $g(r_i)$ . If  $g(r_i)$  is not easily factorable (up to some small trial divisor  $d$ ), try another  $r_i$ . In practice, the trial  $r$ s are usually taken to be  $\lfloor \sqrt{n} \rfloor + k$ , with  $k = 1, 2, \dots$ , which allows the QUADRATIC SIEVE FACTORIZATION METHOD to be used. Continue finding and factoring  $g(r_i)$ s until  $N \equiv \pi d$  are found, where  $\pi$  is the PRIME COUNTING FUNCTION. Now for each  $g(r_i)$ , write

$$g(r_i) = p_1^{a_{1i}} p_2^{a_{2i}} \dots p_N^{a_{Ni}}, \quad (3)$$

and form the EXPONENT VECTOR

$$\mathbf{v}(r_i) = \begin{bmatrix} a_{1i} \\ a_{2i} \\ \vdots \\ a_{Ni} \end{bmatrix}. \quad (4)$$

Now, if  $a_{ki}$  are even for any  $k$ , then  $g(r_i)$  is a SQUARE NUMBER and we have found a solution to (1). If not, look for a linear combination  $\sum_i c_i \mathbf{v}(r_i)$  such that the elements are all even, i.e.,

$$c_1 \begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{N1} \end{bmatrix} + c_2 \begin{bmatrix} a_{12} \\ a_{22} \\ \vdots \\ a_{N2} \end{bmatrix} + \dots + c_N \begin{bmatrix} a_{1N} \\ a_{2N} \\ \vdots \\ a_{NN} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \pmod{2} \quad (5)$$

$$\begin{bmatrix} a_{11} & a_{12} & \dots & a_{1N} \\ a_{21} & a_{22} & \dots & a_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ a_{N1} & a_{N2} & \dots & a_{NN} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_N \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \pmod{2}. \quad (6)$$

Since this must be solved only mod 2, the problem can be simplified by replacing the  $a_{ij}$ s with

$$b_{ij} = \begin{cases} 0 & \text{for } a_{ij} \text{ even} \\ 1 & \text{for } a_{ij} \text{ odd.} \end{cases} \quad (7)$$

GAUSSIAN ELIMINATION can then be used to solve

$$\mathbf{bc} = \mathbf{z} \quad (8)$$

for  $\mathbf{c}$ , where  $\mathbf{z}$  is a VECTOR equal to  $\mathbf{0} \pmod{2}$ . Once  $\mathbf{c}$  is known, then we have

$$\prod_k g(r_k) \equiv \prod_k r_k^2 \pmod{n}, \quad (9)$$

where the products are taken over all  $k$  for which  $c_k = 1$ . Both sides are PERFECT SQUARES, so we have a 50% chance that this yields a nontrivial factor of  $n$ . If it does not, then we proceed to a different  $z$  and repeat the procedure. There is no guarantee that this method will yield a factor, but in practice it produces factors faster than any method using trial divisors. It is especially amenable to parallel processing, since each processor can work on a different value of  $r$ .

#### Dixon's Random Squares Factorization Method

see DIXON'S FACTORIZATION METHOD

#### Dixon's Theorem

$${}_3F_2 \left[ \begin{matrix} n, -x, -y \\ x+n+1, y+n+1 \end{matrix} \right] \\ = \Gamma(x+n+1)\Gamma(y+n+1)\Gamma(\tfrac{1}{2}n+1)\Gamma(x+y+\tfrac{1}{2}n+1) \\ \times \Gamma(n+1)\Gamma(x+y+n+1)\Gamma(x+\tfrac{1}{2}n+1)\Gamma(y+\tfrac{1}{2}n+1),$$

where  ${}_3F_2(a, b, c; d, e; z)$  is a GENERALIZED HYPERGEOMETRIC FUNCTION and  $\Gamma(z)$  is the GAMMA FUNCTION. It can be derived from the DOUGALL-RAMANUJAN IDENTITY. It can be written more symmetrically as

$${}_3F_2(a, b, c; d, e; 1) = \frac{(\tfrac{1}{2}a)!(a-b)!(a-c)!(\tfrac{1}{2}a-b-c)!}{a!(\tfrac{1}{2}a-b)!(\tfrac{1}{2}a-c)!(a-b-c)!},$$

where  $1 + a/2 - b - c$  has a positive REAL PART,  $d = a - b + 1$ , and  $e = a - c + 1$ . The identity can also be written as the beautiful symmetric sum

$$\sum_k (-1)^k \binom{a+b}{a+k} \binom{a+c}{c+k} \binom{b+c}{b+k} = \frac{(a+b+c)!}{a!b!c!}$$

(Petkovšek 1996).

#### Dobiński's Formula

Gives the  $n$ th BELL NUMBER,

$$B_n = \frac{1}{e} \sum_{k=0}^{\infty} \frac{k^n}{k!}. \quad (1)$$

It can be derived by dividing the formula for a STIRLING NUMBER OF THE SECOND KIND by  $m!$ , yielding

$$\frac{m^n}{m!} = \sum_{k=1}^m \left\{ \begin{matrix} n \\ k \end{matrix} \right\} \frac{1}{(m-k)!}. \quad (2)$$

Then

$$\sum_{m=1}^{\infty} \frac{m^n}{m!} \lambda^m = \left( \sum_{k=1}^n \left\{ \begin{matrix} n \\ k \end{matrix} \right\} \lambda^k \right) \left( \sum_{j=0}^{\infty} \frac{\lambda^j}{j!} \right), \quad (3)$$

and

$$\sum_{k=1}^n \left\{ \begin{matrix} n \\ k \end{matrix} \right\} \lambda^k = e^{-\lambda} \sum_{m=1}^{\infty} \frac{m^n}{m!} \lambda^m. \quad (4)$$

Now setting  $\lambda = 1$  gives the identity (Dobiński 1877; Rota 1964; Berge 1971, p. 44; Comtet 1974, p. 211; Roman 1984, p. 66; Lupas 1988; Wilf 1990, p. 106; Chen and Yeh 1994; Pitman 1997).

## Dodecadodecahedron

The UNIFORM POLYHEDRON  $U_{36}$  whose DUAL POLYHEDRON is the MEDIAL RHOMBIC TRIACONTAHEDRON. The solid is also called the GREAT DODECADODECAHEDRON, and its DUAL POLYHEDRON is also called the SMALL STELLATED TRIACONTAHEDRON. It can be obtained by TRUNCATING a GREAT DODECAHEDRON or FACETING a ICOSIDODECAHEDRON with PENTAGONS and covering remaining open spaces with PENTAGRAMS (Holden 1991, p. 103). A FACETED version is the GREAT DODECAHEMICOSAHEDRON. The dodecadodecahedron is an ARCHIMEDEAN SOLID STELLATION. The dodecadodecahedron has SCHLÄFLI SYMBOL  $\{\frac{5}{2}, 5\}$  and WYTHOFF SYMBOL  $2|\frac{5}{2}5$ . Its faces are  $12\{\frac{5}{2}\} + 12\{5\}$ , and its CIRCUMRADIUS for unit edge length is

$$R = 1.$$

## Dodecagon

The constructible regular 12-sided POLYGON with SCHLÄFLI SYMBOL  $\{12\}$ . The INRADIUS  $r$ , CIRCUMRADIUS  $R$ , and AREA  $A$  can be computed directly from

the formulas for a general regular POLYGON with side length  $s$  and  $n = 12$  sides,

$$r = \frac{1}{2}s \cot\left(\frac{\pi}{12}\right) = \frac{1}{2}(2 + \sqrt{3})s \quad (1)$$

$$R = \frac{1}{2}s \cot\left(\frac{\pi}{12}\right) = \frac{1}{2}(\sqrt{2} + \sqrt{6})s \quad (2)$$

$$A = \frac{1}{4}ns^2 \cot\left(\frac{\pi}{12}\right) = 3(2 + \sqrt{3})s^2. \quad (3)$$

A PLANE PERPENDICULAR to a  $C_5$  axis of a DODECAHEDRON or ICOSAHEDRON cuts the solid in a regular DECAGONAL CROSS-SECTION (Holden 1991, pp. 24–25).

The GREEK, LATIN, and MALTESE CROSSES are all irregular dodecagons.

see also DECAGON, DODECAGRAM, DODECAHEDRON, GREEK CROSS, LATIN CROSS, MALTESE CROSS, TRIGONOMETRY VALUES— $\pi/12$ , UNDECAGON

## Dodecagram

The STAR POLYGON  $\{\frac{12}{5}\}$ .

see also STAR POLYGON, TRIGONOMETRY VALUES— $\pi/12$

**Dodecahedral Conjecture**

In any unit SPHERE PACKING, the volume of any VORONOI CELL around any sphere is at least as large as a regular DODECAHEDRON of INRADIUS 1. If true, this would provide a bound on the densest possible sphere packing greater than any currently known. It would not, however, be sufficient to establish the KEPLER CONJECTURE.

**Dodecahedral Graph**

A POLYHEDRAL GRAPH.

see also CUBICAL GRAPH, ICOSAHERAL GRAPH, OCTAHEDRAL GRAPH, TETRAHEDRAL GRAPH

**Dodecahedral Space**

see POINCARÉ MANIFOLD

**Dodecahedron**

The regular dodecahedron is the PLATONIC SOLID ( $P_4$ ) composed of 20 VERTICES, 30 EDGES, and 12 PENTAGONAL FACES. It is given by the symbol  $12\{5\}$ , the SCHLÄFLI SYMBOL  $\{5, 3\}$ . It is also UNIFORM POLYHEDRON  $U_{23}$  and has WYTHOFF SYMBOL  $3|25$ . The dodecahedron has the ICOSAHERAL GROUP  $I_h$  of symmetries.

A PLANE PERPENDICULAR to a  $C_3$  axis of a dodecahedron cuts the solid in a regular HEXAGONAL CROSS-SECTION (Holden 1991, p. 27). A PLANE PERPENDICULAR to a  $C_5$  axis of a dodecahedron cuts the solid in a regular DECAGONAL CROSS-SECTION (Holden 1991, p. 24).

The DUAL POLYHEDRON of the dodecahedron is the ICOSAHERON.

When the dodecahedron with edge length  $\sqrt{10 - 2\sqrt{5}}$  is oriented with two opposite faces parallel to the  $xy$ -PLANE, the vertices of the top and bottom faces lie at  $z = \pm(\phi + 1)$  and the other VERTICES lie at  $z = \pm(\phi - 1)$ , where  $\phi$  is the GOLDEN RATIO. The explicit coordinates are

$$\pm \left( 2 \cos\left(\frac{2}{5}\pi i\right), 2 \sin\left(\frac{2}{5}\pi i\right), \phi + 1 \right) \quad (1)$$

$$\pm \left( 2\phi \cos\left(\frac{2}{5}\pi i\right), 2\phi \sin\left(\frac{2}{5}\pi i\right), \phi - 1 \right) \quad (2)$$

with  $i = 0, 1, \dots, 4$ , where  $\phi$  is the GOLDEN RATIO. Explicitly, these coordinates are

$$\mathbf{x}_{10}^{\pm} = \pm(2, 0, \frac{1}{2}(3 + \sqrt{5})) \quad (3)$$

$$\mathbf{x}_{11}^{\pm} = \pm(\frac{1}{2}(\sqrt{5} - 1), \frac{1}{2}\sqrt{10 + 2\sqrt{5}}, \frac{1}{2}(3 + \sqrt{5})) \quad (4)$$

$$\mathbf{x}_{12}^{\pm} = \pm(-\frac{1}{2}(1 + \sqrt{5}), \frac{1}{2}\sqrt{10 - 2\sqrt{5}}, \frac{1}{2}(3 + \sqrt{5})) \quad (5)$$

$$\mathbf{x}_{13}^{\pm} = \pm(-\frac{1}{2}(1 + \sqrt{5}), -\frac{1}{2}\sqrt{10 - 2\sqrt{5}}, \frac{1}{2}(3 + \sqrt{5})) \quad (6)$$

$$\mathbf{x}_{14}^{\pm} = \pm(\frac{1}{2}(\sqrt{5} - 1), -\frac{1}{2}\sqrt{10 + 2\sqrt{5}}, \frac{1}{2}(3 + \sqrt{5})) \quad (7)$$

$$\mathbf{x}_{20}^{\pm} = \pm(1 + \sqrt{5}, 0, \frac{1}{2}(\sqrt{5} - 1)) \quad (8)$$

$$\mathbf{x}_{21}^{\pm} = \pm(1, \sqrt{5 + 2\sqrt{5}}, \frac{1}{2}(\sqrt{5} - 1)) \quad (9)$$

$$\mathbf{x}_{22}^{\pm} = \pm(-\frac{1}{2}(3 + \sqrt{5}), \frac{1}{2}\sqrt{10 + 2\sqrt{5}}, \frac{1}{2}(\sqrt{5} - 1)) \quad (10)$$

$$\mathbf{x}_{23}^{\pm} = \pm(-\frac{1}{2}(3 + \sqrt{5}), -\frac{1}{2}\sqrt{10 + 2\sqrt{5}}, \frac{1}{2}(\sqrt{5} - 1)) \quad (11)$$

$$\mathbf{x}_{24}^{\pm} = \pm(1, -\sqrt{5 + 2\sqrt{5}}, \frac{1}{2}(\sqrt{5} - 1)), \quad (12)$$

where  $\mathbf{x}_{1i}^+$  are the top vertices,  $\mathbf{x}_{2i}^+$  are the vertices above the mid-plane,  $\mathbf{x}_{2i}^-$  are the vertices below the mid-plane, and  $\mathbf{x}_{2i}^-$  are the bottom vertices. The VERTICES of a dodecahedron can be given in a simple form for a dodecahedron of side length  $a = \sqrt{5} - 1$  by  $(0, \pm\phi^{-1}, \pm\phi)$ ,  $(\pm\phi, 0, \pm\phi^{-1})$ ,  $(\pm\phi^{-1}, \pm\phi, 0)$ , and  $(\pm 1, \pm 1, \pm 1)$ .

For a dodecahedron of unit edge length  $a = 1$ , the CIRCUMRADIUS  $R'$  and INRADIUS  $r'$  of a PENTAGONAL FACE are

$$R' = \frac{1}{10} \sqrt{50 + 10\sqrt{5}} \quad (13)$$

$$r' = \frac{1}{10} \sqrt{25 + 10\sqrt{5}}. \quad (14)$$

The SAGITTA  $x$  is then given by

$$x \equiv R' - r' = \frac{1}{10} \sqrt{125 - 10\sqrt{5}}. \quad (15)$$

Now consider the following figure.

Using the PYTHAGOREAN THEOREM on the figure then gives

$$z_1^2 + m^2 = (R' + r')^2 \quad (16)$$

$$z_2^2 + (m - x)^2 = 1 \quad (17)$$

$$\left(\frac{z_1 + z_2}{2}\right)^2 + R'^2 = \left(\frac{z_1 - z_2}{2}\right)^2 + (m + r')^2. \quad (18)$$

Equation (18) can be written

$$z_1 z_2 + r^2 = (m + r')^2. \quad (19)$$

Solving (16), (17), and (19) simultaneously gives

$$m = r' = \frac{1}{10} \sqrt{25 + 10\sqrt{5}} \quad (20)$$

$$z_1 = 2r' = \frac{1}{5} \sqrt{25 + 10\sqrt{5}} \quad (21)$$

$$z_2 = R' = \frac{1}{10} \sqrt{50 + 10\sqrt{5}}. \quad (22)$$

The INRADIUS of the dodecahedron is then given by

$$r = \frac{1}{2}(z_1 + z_2), \quad (23)$$

so

$$\begin{aligned} r^2 &= \frac{1}{4} \left( \frac{1}{10} \sqrt{50 + 10\sqrt{5}} + \frac{1}{5} \sqrt{25 + 10\sqrt{5}} \right)^2 \\ &= \frac{1}{40} (25 + 11\sqrt{5}), \end{aligned} \quad (24)$$

and

$$r = \sqrt{\frac{25 + 11\sqrt{5}}{40}} = \frac{1}{20} \sqrt{250 + 110\sqrt{5}} = 1.11351\dots \quad (25)$$

Now,

$$\begin{aligned} R^2 &= R'^2 + r^2 = \left[ \frac{1}{100} (50 + 10\sqrt{5}) + \frac{1}{400} (250 + 110\sqrt{5}) \right] \\ &= \frac{3}{8} (3 + \sqrt{5}), \end{aligned} \quad (26)$$

and the CIRCUMRADIUS is

$$R = a \sqrt{\frac{3}{8} (3 + \sqrt{5})} = \frac{1}{4} (\sqrt{15} + \sqrt{3}) = 1.40125\dots \quad (27)$$

The INTERRADIUS is given by

$$\begin{aligned} \rho^2 &= r'^2 + r^2 = \left[ \frac{1}{100} (25 + 10\sqrt{5}) + \frac{1}{400} (250 + 110\sqrt{5}) \right] \\ &= \frac{1}{8} (7 + 3\sqrt{5}), \end{aligned} \quad (28)$$

so

$$\rho = \frac{1}{4} (3 + \sqrt{5}) = 1.30901\dots \quad (29)$$

The AREA of a single FACE is the AREA of a PENTAGON,

$$A = \frac{1}{4} \sqrt{25 + 10\sqrt{5}}. \quad (30)$$

The VOLUME of the dodecahedron can be computed by summing the volume of the 12 constituent PENTAGONAL PYRAMIDS,

$$\begin{aligned} V &= 12 \left( \frac{1}{3} Ar \right) \\ &= 12 \left( \frac{1}{3} \right) \left( \frac{1}{4} \sqrt{25 + 10\sqrt{5}} \right) \left( \frac{1}{20} \sqrt{250 + 110\sqrt{5}} \right) \\ &= \frac{1}{20} (75 + 35\sqrt{5}) = \frac{1}{4} (15 + 7\sqrt{5}). \end{aligned} \quad (31)$$

Apollonius showed that the VOLUME  $V$  and SURFACE AREA  $A$  of the dodecahedron and its DUAL the ICOSAHEDRON are related by

$$\frac{V_{\text{icosahedron}}}{V_{\text{dodecahedron}}} = \frac{A_{\text{icosahedron}}}{A_{\text{dodecahedron}}} \quad (32)$$

The HEXAGONAL SCALENOHEDRON is an irregular dodecahedron.

**Dodecahedron-Icosahedron Compound**

A POLYHEDRON COMPOUND of a DODECAHEDRON and ICOSAHEDRON which is most easily constructed by adding 20 triangular PYRAMIDS, constructed as above, to an ICOSAHEDRON. In the compound, the DODECAHEDRON and ICOSAHEDRON are rotated  $\pi/5$  radians with respect to each other, and the ratio of the ICOSAHEDRON to DODECAHEDRON edges lengths are the GOLDEN RATIO  $\phi$ .

The above figure shows compounds composed of a DODECAHEDRON of unit edge length and ICOSAHEDRON having edge lengths varying from  $\sqrt{5}/2$  (inscribed in the dodecahedron) to 2 (circumscribed about the dodecahedron).

The intersecting edges of the compound form the DIAGONALS of 30 RHOMBUSES comprising the TRIACONTAHEDRON, which is the DUAL POLYHEDRON of the ICOSIDODECAHEDRON (Ball and Coxeter 1987). The dodecahedron-icosahedron is the first STELLATION of the ICOSIDODECAHEDRON.

 Wenninger, M. J. *Polyhedron Models*. Cambridge, England: Cambridge University Press, p. 76, 1989.

**Dodecahedron Stellations**

The dodecahedron has three STELLATIONS: the GREAT DODECAHEDRON, GREAT STELLATED DODECAHEDRON, and SMALL STELLATED DODECAHEDRON. The only STELLATIONS of PLATONIC SOLIDS which are UNIFORM POLYHEDRA are these three and one ICOSAHEDRON STELLATION. Bulatov has produced 270 stellations of a deformed dodecahedron.

Bulatov, V.v "270 Stellations of Deformed Dodecahedron."  
<http://www.physics.orst.edu/~bulatov/polyhedra/dodeca270/>.

**Dodecahedron 2-Compound**

A compound of two dodecahedra with the symmetry of the CUBE arises by combining the two dodecahedra rotated  $90^\circ$  with respect to each other about a common  $C_2$  axis (Holden 1991, p. 37).

see also POLYHEDRON COMPOUND

**References**

Holden, A. *Shapes, Space, and Symmetry*. New York: Dover, 1991.

**Domain**

A connected OPEN SET. The term domain is also used to describe the set of values  $D$  for which a FUNCTION is defined. The set of values to which  $D$  is sent by the function (MAP) is then called the RANGE.

see also MAP, ONE-TO-ONE, ONTO, RANGE (IMAGE), REINHARDT DOMAIN

**Domain Invariance Theorem**

The Invariance of Domain Theorem is that if  $f : A \rightarrow \mathbb{R}^n$  is a ONE-TO-ONE continuous MAP from  $A$ , a compact subset of  $\mathbb{R}^n$ , then the interior of  $A$  is mapped to the interior of  $f(A)$ .

see also DIMENSION INVARIANCE THEOREM

**Dome**

see BOHEMIAN DOME, GEODESIC DOME, HEMISPHERE, SPHERICAL CAP, TORISPHERICAL DOME, VAULT

**Dominance**

The dominance RELATION on a SET of points in EUCLIDEAN  $n$ -space is the INTERSECTION of the  $n$  coordinate-wise orderings. A point  $p$  dominates a point  $q$  provided that every coordinate of  $p$  is at least as large as the corresponding coordinate of  $q$ .

The dominance orders in  $\mathbb{R}^n$  are precisely the POSETS of DIMENSION at most  $n$ .

see also PARTIALLY ORDERED SET, REALIZER

**Domino**

The unique 2-POLYOMINO consisting of two equal squares connected along a complete EDGE.

The FIBONACCI NUMBER  $F_{n+1}$  gives the number of ways for  $2 \times 1$  dominoes to cover a  $2 \times n$  CHECKERBOARD, as illustrated in the following diagrams (Dickau).

#### Doob's Theorem

A theorem proved by Doob (1942) which states that any random process which is both GAUSSIAN and MARKOV has the following forms for its correlation function, spectral density, and probability densities:

$$\begin{aligned}
 C_y(\tau) &= \sigma_y^2 e^{-\tau/\tau_r} \\
 G_y(f) &= \frac{4\tau_r^{-1}\sigma_y^2}{(2\pi f)^2 + \tau_r^{-2}} \\
 p_1(y) &= \frac{1}{\sqrt{2\pi\sigma_y^2}} e^{-(y-\bar{y})^2/2\sigma_y^2} \\
 p_2(y_1|y_2, \tau) &= \frac{1}{\sqrt{2\pi(1 - e^{-2\tau/\tau_r})\sigma_y^2}} \\
 &\quad \times \exp \left\{ -\frac{[(y_2 - \bar{y}) - e^{-\tau/\tau_r}(y_1 - \bar{y})]^2}{2(1 - e^{-2\tau/\tau_r})\sigma_y^2} \right\},
 \end{aligned}$$

where  $\bar{y}$  is the MEAN,  $\sigma_y$  the STANDARD DEVIATION, and  $\tau_r$  the relaxation time.

#### References

#### Dot

The "dot"  $\cdot$  has several meanings in mathematics, including MULTIPLICATION ( $a \cdot b$  is pronounced "a times b"), computation of a DOT PRODUCT ( $\mathbf{a} \cdot \mathbf{b}$  is pronounced "a dot b"), or computation of a time DERIVATIVE ( $\dot{a}$  is pronounced "a dot").

see also DERIVATIVE, DOT PRODUCT, TIMES

#### Dot Product

The dot product can be defined by

$$\mathbf{X} \cdot \mathbf{Y} = |\mathbf{X}| |\mathbf{Y}| \cos \theta, \quad (1)$$

where  $\theta$  is the angle between the vectors. It follows immediately that  $\mathbf{X} \cdot \mathbf{Y} = 0$  if  $\mathbf{X}$  is PERPENDICULAR to  $\mathbf{Y}$ . The dot product is also called the INNER PRODUCT and written  $\langle a, b \rangle$ . By writing

$$A_x = A \cos \theta_A \quad B_x = B \cos \theta_B \quad (2)$$

$$A_y = A \sin \theta_A \quad B_y = B \sin \theta_B, \quad (3)$$

it follows that (1) yields

$$\begin{aligned}
 \mathbf{A} \cdot \mathbf{B} &= AB \cos(\theta_A - \theta_B) \\
 &= AB(\cos \theta_A \cos \theta_B + \sin \theta_A \sin \theta_B) \\
 &= A \cos \theta_A B \cos \theta_B + A \sin \theta_A B \sin \theta_B \\
 &= A_x B_x + A_y B_y.
 \end{aligned} \quad (4)$$

So, in general,

$$\mathbf{X} \cdot \mathbf{Y} = x_1 y_1 + \dots + x_n y_n. \quad (5)$$

The dot product is COMMUTATIVE

$$\mathbf{X} \cdot \mathbf{Y} = \mathbf{Y} \cdot \mathbf{X}, \quad (6)$$

ASSOCIATIVE

$$(\mathbf{rX}) \cdot \mathbf{Y} = \mathbf{r}(\mathbf{X} \cdot \mathbf{Y}), \quad (7)$$

and DISTRIBUTIVE

$$\mathbf{X} \cdot (\mathbf{Y} + \mathbf{Z}) = \mathbf{X} \cdot \mathbf{Y} + \mathbf{X} \cdot \mathbf{Z}. \quad (8)$$

The DERIVATIVE of a dot product of VECTORS is

$$\frac{d}{dt} [\mathbf{r}_1(t) \cdot \mathbf{r}_2(t)] = \mathbf{r}_1(t) \cdot \frac{d\mathbf{r}_2}{dt} + \frac{d\mathbf{r}_1}{dt} \cdot \mathbf{r}_2(t). \quad (9)$$

The dot product is invariant under rotations

$$\begin{aligned}\mathbf{A}' \cdot \mathbf{B}' &= A'_i B'_i = a_{ij} A_j a_{ik} B_k = (a_{ij} a_{ik}) A_j B_k \\ &= \delta_{jk} A_j B_k = A_j B_j = \mathbf{A} \cdot \mathbf{B},\end{aligned}\quad (10)$$

where EINSTEIN SUMMATION has been used.

The dot product is also defined for TENSORS  $A$  and  $B$  by

$$A \cdot B = A^\alpha B_\alpha. \quad (11)$$

## Double Factorial

The double factorial is a generalization of the usual FACTORIAL  $n!$  defined by

$$n!! \equiv \begin{cases} n \cdot (n-2) \cdots 5 \cdot 3 \cdot 1 & n \text{ odd} \\ n \cdot (n-2) \cdots 6 \cdot 4 \cdot 2 & n \text{ even} \\ 1 & n = -1, 0. \end{cases} \quad (1)$$

For  $n = 0, 1, 2, \dots$ , the first few values are 1, 1, 2, 3, 8, 15, 48, 105, 384, ... (Sloane's A006882).

There are many identities relating double factorials to FACTORIALS. Since

$$\begin{aligned} (2n+1)!!2^n n! &= [(2n+1)(2n-1)\cdots 1][2n][2(n-1)][2(n-2)]\cdots 2(1) \\ &= [(2n+1)(2n-1)\cdots 1][2n(2n-2)(2n-4)\cdots 2] \\ &= (2n+1)(2n)(2n-1)(2n-2)(2n-3)(2n-4)\cdots 2(1) \\ &= (2n+1)!, \end{aligned} \quad (2)$$

it follows that  $(2n+1)!! = \frac{(2n+1)!}{2^n n!}$ . Since

$$\begin{aligned} (2n)!! &= (2n)(2n-2)(2n-4)\cdots 2 \\ &= [2(n)][2(n-1)][2(n-2)]\cdots 2 = 2^n n!, \end{aligned} \quad (3)$$

it follows that  $(2n)!! = 2^n n!$ . Since

$$\begin{aligned} (2n-1)!!2^n n! &= [(2n-1)(2n-3)\cdots 1][2n][2(n-1)][2(n-2)]\cdots 2(1) \\ &= (2n-1)(2n-3)\cdots 1[2n(2n-2)(2n-4)\cdots 2] \\ &= 2n(2n-1)(2n-2)(2n-3)(2n-4)\cdots 2(1) \\ &= (2n)!, \end{aligned} \quad (4)$$

it follows that

$$(2n-1)!! = \frac{(2n)!}{2^n n!}. \quad (5)$$

Similarly, for  $n = 0, 1, \dots$ ,

$$(-2n-1)!! = \frac{(-1)^n}{(2n-1)!!} = \frac{(-1)n2^n n!}{(2n)!}. \quad (6)$$

For  $n$  ODD,

$$\begin{aligned} \frac{n!}{n!!} &= \frac{n(n-1)(n-2)\cdots(1)}{n(n-2)(n-4)\cdots(1)} \\ &= (n-1)(n-3)\cdots(1) = (n-1)!!. \end{aligned} \quad (7)$$

For  $n$  EVEN,

$$\begin{aligned} \frac{n!}{n!!} &= \frac{n(n-1)(n-2)\cdots(2)}{n(n-2)(n-4)\cdots(2)} \\ &= (n-1)(n-3)\cdots(2) = (n-1)!!. \end{aligned} \quad (8)$$

Therefore, for any  $n$ ,

$$\frac{n!}{n!!} = (n-1)!! \quad (9)$$

$$n! = n!!(n-1)!! \quad (10)$$

The FACTORIAL may be further generalized to the MULTIFACTORIAL

## Double Folium

see BIFOLIUM

## Double-Free Set

A SET of POSITIVE integers is double-free if, for any integer  $x$ , the SET  $\{x, 2x\} \not\subset S$  (or equivalently, if  $x \in S$  IMPLIES  $2x \notin S$ ). Define

$$r(n) = \max\{S : S \subset \{1, 2, \dots, n\} \text{ is double-free}\}.$$

Then an asymptotic formula is

$$r(n) \sim \frac{2}{3}n + \mathcal{O}(\ln n)$$

(Wang 1989).

- Fischer, G. (Ed.). *Mathematical Models from the Collections of Universities and Museums*. Braunschweig, Germany: Vieweg, pp. 12–13, 1986.

**Double Sixes**

Two sextuples of SKEW LINES on the general CUBIC SURFACE such that each line of one is SKEW to one LINE in the other set. Discovered by Schläfli.

see also BOXCARS, CUBIC SURFACE, SOLOMON'S SEAL LINES

**References**

- Fischer, G. (Ed.). *Mathematical Models from the Collections of Universities and Museums*. Braunschweig, Germany: Vieweg, p. 11, 1986.

**Double Sum**

A nested sum over two variables. Identities involving double sums include the following:

$$\sum_{p=0}^{\infty} \sum_{q=0}^p a_{q,p-q} = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} a_{n,m} = \sum_{r=0}^{\infty} \sum_{s=0}^{\lfloor r/2 \rfloor} a_{s,r-2s}, \quad (1)$$

where

$$\lfloor r/2 \rfloor = \begin{cases} \frac{1}{2}r & r \text{ even} \\ \frac{1}{2}(r-1) & r \text{ odd} \end{cases} \quad (2)$$

is the FLOOR FUNCTION, and

$$\sum_{i=1}^n \sum_{j=1}^n x_i x_j = n^2 \langle x^2 \rangle. \quad (3)$$

Consider the sum

$$S(a, b, c; s) = \sum_{(m,n) \neq (0,0)} (am^2 + bmn + cn^2)^{-s} \quad (4)$$

over binary QUADRATIC FORMS. If  $S$  can be decomposed into a linear sum of products of DIRICHLET  $L$ -SERIES, it is said to be solvable. The related sums

$$S_1(a, b, c; s) = \sum_{(m,n) \neq (0,0)} (-1)^m (am^2 + bmn + cn^2)^{-s} \quad (5)$$

$$S_2(a, b, c; s) = \sum_{(m,n) \neq (0,0)} (-1)^n (am^2 + bmn + cn^2)^{-s} \quad (6)$$

$$S_{1,2}(a, b, c; s) = \sum_{(m,n) \neq (0,0)} (-1)^{m+n} (am^2 + bmn + cn^2)^{-s} \quad (7)$$

can also be defined, which gives rise to such impressive FORMULAS as

$$S_1(1, 0, 58; 1) = -\frac{\pi \ln(27 + 5\sqrt{29})}{\sqrt{58}}. \quad (8)$$

A complete table of the principal solutions of all solvable  $S(a, b, c; s)$  is given in Glasser and Zucker (1980, pp. 126–131).

**Doubly Magic Square**

see BIMAGIC SQUARE

**Dougall-Ramanujan Identity**

Discovered by Ramanujan around 1910. From Hardy (1959, pp. 102–103),

$$\sum_{n=0}^{\infty} (-1)^n (s+2n) \frac{s^{(n)}}{1^{(n)}} \frac{(x+y+z+u+2s+1)^{(n)}}{(x+y+z+u-s)_{(n)}} \times \prod_{x,y,z,u} \frac{x_{(n)}}{(x+s+1)^{(n)}} = \frac{s}{\Gamma(s+1)\Gamma(x+y+z+u+s+1)} \times \prod_{x,y,z,u} \frac{\Gamma(x+s+1)\Gamma(y+z+u+s+1)}{\Gamma(z+u+s+1)}, \quad (1)$$

where

$$a^{(n)} \equiv a(a+1) \cdots (a+n-1) \quad (2)$$

$$a_{(n)} \equiv a(a-1) \cdots (a-n+1) \quad (3)$$

(here, the POCHHAMMER SYMBOL has been written  $a^{(n)}$ ). This can be rewritten as

$${}_7F_6 \left[ \begin{matrix} s, 1 + \frac{1}{2}s, -x-y, -z, -u, x-y+z+u+2s+1 \\ \frac{1}{2}s, x+s+1, y+s+1, z+s+1, u+s+1, -x-y-z-u-s \end{matrix} ; 1 \right] = \frac{1}{\Gamma(s+1)\Gamma(x+y+z+u+s+1)} \times \prod_{x,y,z,u} \frac{\Gamma(x+s+1)\Gamma(y+z+u+s+1)}{\Gamma(z+u+s+1)}. \quad (4)$$

In a more symmetric form, if  $n = 2a_1 + 1 = a_2 + a_3 + a_4 + a_5$ ,  $a_6 = 1 + a_1/2$ ,  $a_7 = -n$ , and  $b_i = 1 + a_1 - a_{i+1}$  for  $i = 1, 2, \dots, 6$ , then

$${}_7F_6 \left[ \begin{matrix} a_1, a_2, a_3, a_4, a_5, a_6, a_7 \\ b_1, b_2, b_3, b_4, b_5, b_6 \end{matrix} ; 1 \right] = \frac{(a_1+1)_n (a_1-a_2-a_3+1)_n}{(a_1-a_2+1)_n (a_1-a_3+1)_n} \times \frac{(a_1-a_2-a_4+1)_n (a_1-a_3-a_4+1)_n}{(a_1-a_4+1)_n (a_1-a_2-a_3-a_4+1)_n}, \quad (5)$$

where  $(a)_n$  is the POCHHAMMER SYMBOL (Petkovšek *et al.* 1996).

The identity is a special case of JACKSON'S IDENTITY.

**Douglas-Neumann Theorem**

If the lines joining corresponding points of two directly similar figures are divided proportionally, then the LOCUS of the points of the division will be a figure directly similar to the given figures.

**Dowker Notation**

A simple way to describe a knot projection. The advantage of this notation is that it enables a KNOT DIAGRAM to be drawn quickly.

For an oriented ALTERNATING KNOT with  $n$  crossings, begin at an arbitrary crossing and label it 1. Now follow the undergoing strand to the next crossing, and denote it 2. Continue around the knot following the same strand until each crossing has been numbered twice. Each crossing will have one even number and one odd number, with the numbers running from 1 to  $2n$ .
